Another claim made for metal wheels is that their strength is greater than wood wheels. Assuming the cast steel wheels to be free from defects, and to have the chemical and physical characteristics recommended by the iron and steel division, these wheels certainly develop marvelous resistance to shocks. I witnessed a test of such a wheel recently which was subjected to the impact of a weight swung as a pendulum against the side of the felloe and the wheel was deformed beyond the semblance of a wheel and even then did not show any fracture. At the same time, as has been pointed out by the iron and steel division, steel castings cannot be inspected against blow holes, and had the wheel in question contained some concealed defect, failure in testing would probably have resulted. The difficulty in securing uniform steel castings free from defects and conforming to the S. A. E. standards is generally conceded and several of the foundries making cast steel wheels in this country, at the present time, are having difficulty in making steel castings of other motor truck parts which will pass the inspection of some of their customers. As to the strength of well constructed and properly designed wood wheels, the front wheel of a truck manufactured by one of my clients came in contact recently with a road obstruction with such impact that the strain broke the steering gear, but the wheel was uninjured, and on another truck a rear wheel was subjected to such an impact that the axle spindle was bent without injury to the wheel. Therefore, on the question of strength, that of the high grade wood wheel is entirely adequate for commercial purposes.

The contention is also made that the metal wheel will dissipate heat more effectively than the wood wheel. There has come under my observation no case in which a truck tire on a modern motor truck has been injured by lack of heat radiation under service conditions. I assume that the heat developed in a solid rubber tire is due to the deformation of the rubber and this is greatest near the surface of the rubber which comes in contact with the ground. This surface is in contact with the air and I should expect that the heat would be radiated through the air more easily than transmitted through the base of the tire to the wheel and hence radiated by the wheel, felloe and spokes.

The fourth point in considering the relative merits of wood and metal wheels is the comparative cost and weight. From information received from one of my clients regarding wood wheels being regularly manufactured and used on this company's trucks, and from information received from the chief engineer of one of the companies which is bringing out cast steel wheels, the following comparison of weight and cost has been made:

Set of wheels for three-ton truck to take 36-inch by five-inch tires, front; and 40-inch by four-inch dual tires, rear; wood wheels equipped with S. A. E. band and Timken hubs and flanges—steel wheels having band and hubs integral—

Wood	Steel	Increase of Steel over Wood
	Weight.	
Front 122 lb. each	151 lb.	12.4%
Rear 212 lb. each	373 lb.	76.0%
Set 668 lb.	1048 lb.	57.0%—380 lb.
	Cost.	
Front each $20.00	$26.80	34.0%
Rear each $30.00	52.10	74.0%
Set each $100.00	157.80	57.8%—$57.80

Information obtained from a European manufacturer of cast steel wheels indicates that their weight is substantially the same as American cast steel wheels, but the price is 25 to 50 per cent. higher, thereby placing the steel wheel at a still further disadvantage as far as cost is concerned. Consequently, it would appear that the cast steel wheels are both costlier and heavier than the wood wheels. The burden of proof seems to rest with the metal wheel manufacturer, that they have an economic advantage over the wood wheels, resulting in a financial saving to the owner of the truck equipped with metal wheels.

There is one type of metal wheel which might overcome the disadvantage, real or fancied, of the wood wheel, and which would at the same time eliminate the element of risk always existent in a casting, and also the criticism of the built-up structural steel wheel, the loosening rivets. This is the drop forged wheel. Drop forgings of high-grade steel, which after suitable heat treatments, develop extraordinary physical characteristics, would, in my opinion, be an ideal construction, unless their first cost proved prohibitive. I hope we may hear something from the drop forging experts among our membership in regard to the feasibility of such a construction for motor truck wheels.

As stated at the outset of this paper, its purpose is to stimulate discussion and secure additional data, by which the motor truck designer may be benefited and assisted in his work. I trust it may accomplish its purpose.

JACKSHAFT VS. REAR WHEEL BRAKES.

"Jackshaft vs. Double Rear Wheel Brakes" was the title of a paper by Arthur M. Laycock, which was in part:

An investigation from a designer's outlook on the following lines may prove instructive: 1, danger of braking through any intermediary and not direct; 2, the detrimental effects of brakes on end of jackshaft; 3, effect on universal joints and differential gears.

Our government in its specifications for army trucks has without any question taken the right step in insisting on both brakes being on the rear wheels. This must have a beneficial effect on the trade in general. Similar enactments should be made in all our large cities to save property and life in congested streets. The London Scotland Yard authorities, who are represented by a capable and efficient board of engineers, now insist that all motor 'buses and public service vehicles have both brakes fitted to the rear wheels.

Whatever may be the status as to brake location on the pleasure car, there is no comparison between the energy stored up in a six-ton machine and the heaviest of pleasure cars. In case of collision at a given speed the disastrous possibilities of brake failure are more pronounced in commercial than in pleasure car work.

Many designers have the opinion that you can take a pleasure car axle and use it as a jackshaft. This is all right if jackshaft brakes are not used, the conditions then being analogous to pleasure car work so far as the jackshaft ends are concerned; in other words, you can never impose strains greater than the full torque of the motor. But with the jackshaft brake you may exceed this from two to three times; the larger the truck the more pronounced, of course, is the difference. Figures based on a six-ton truck are so glaring in this respect that the outer ends must be so large as to be out of all proportion to the rest of the truck.

Take, for example, a six-ton truck, 50 per cent. overload, 80 per cent. on the rear, which would be equal to about 10,000 pounds on each wheel; 40-inch rear wheel diameter, sprocket diameters six inches and 22 inches, countershaft brake drum diameter 12 inches and coefficient of friction between the road and the tires 75 per cent.

Considering the jackshaft brake first.

$$\text{The pull on chain} = \frac{10{,}000 \times .75 \times 20}{11} = 13{,}650 \text{ lbs.}$$

The horizontal component of 13,650 lbs. = 13,300 lbs.

$$\text{Reaction on fulcrum pin A} = \frac{13{,}300 \text{ lbs.} \times 3}{6} = 6650 \text{ lbs.}$$

Plotting the above forces the resultant reaction on the sprocket bearing is 19,950 lbs.

The distance from the centre line of the sprocket to the centre line of the sprocket bearing being 3.5 inches, and the distance from the centre line of the sprocket bearing to the centre line of the countershaft 20 inches, the total load on bearing is equal to

$$\frac{19{,}950 \times 3.5}{20} + 19{,}950 = 23{,}445 \text{ lbs.}$$

Considering a motor of 50 horsepower, 1000 revolutions a

minute, with 12:1 reduction, that is, 4:1 in the bevels and 3:1 in the transmission, we obtain

$$\text{Pull in chain required in driving} = \frac{50 \times 63{,}000}{83 \times 2 \times 3} = 6300 \text{ lbs.}$$

You will notice that in the double rear wheel brake construction it is utterly impossible to impose any load whatever on the jackshaft ends except, of course, the reaction from the radius rods, which can be taken easily direct on the frame. The figures given undoubtedly account for the many failures as well as for the exceptionally large brackets used by some. Almost 12 tons is quite an item to take care of. It seems perfectly absurd to introduce these strains on the end of the jackshaft and more than double the work on the chain. Where pleasure car axles, with brakes attached, have been used for jackshafts there has been more or less trouble. The bearings, tubes and drive shafts are subjected to stresses they were never designed for.

In the above paragraphs I have endeavored to demonstrate conditions the jackshaft brake imposes on the surrounding parts. This has not been considered by any means from every angle, but sufficient, I think, to show the superiority of the double-brakes-on-the-rear over the jackshaft brake design. It is manifest that the wheels are the only place for the brakes, spelling finality in design as to their location, unless dependability and cost be sacrificed in the extreme.

In making a diagnosis of the situation pertaining to propeller shaft brakes, the same questions may be asked and like answers returned as in the case of jackshaft brakes. The question may be raised as to the propeller shaft brake eliminating to some extent the tendency of skidding. * * * It is obvious that the durability of joints and gears must be sacrificed with the propeller shaft brake, and I am sure that a good

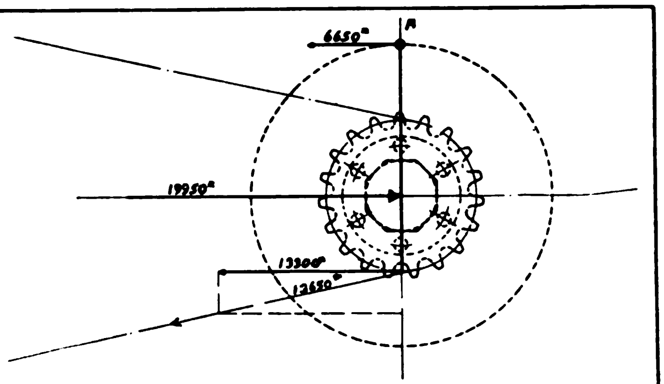

Fig. 1

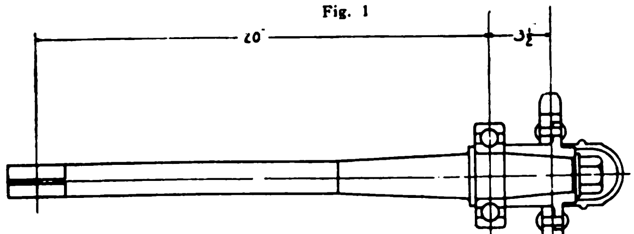

Fig. 2

equalizer on the brake rock shaft with double brakes on the rear wheels leaves nothing to be desired so far as side skidding is concerned, some of our largest makers having always retained this construction.

The replacement of joints, however, is not so expensive or troublesome as the repair of broken differential gears. Precisely the same theory holds good here; most of our differential gears are working under exceedingly high pressures. In fact, it is quite common practise to work at from 75,000 to 100,000 pounds, the stresses being the resultant of the full torque of the engine and the reduction in transmission. The steel used here will probably range from 100,000 to 150,000 pounds a square inch elastic limit. Very few makers have a greater factor of safety than 2:1. These parts are also subjected to the same 200 per cent. overload from the rear, which you will admit must be a pretty warm place for gears already stressed to 100,000 pounds a square inch from engine torque alone. Considering that these extreme loads are of a reversible nature, it is very surprising the gears stand up at all, speaking well for the grade of steel used and the particularly fine heat treatment obtained in our large factories.

The drive shafts are usually stressed very high, even in the full floating type. In the semi-floating construction the combined bending torsion is very rarely taken care of adequately, figuring from the road wheel end, whereas it may be quite safe as to taking the torque of the motor only. Take for example a five-ton worm driven truck of approximate weight with body of 8000 pounds; figuring 25 per cent. overload and 80 per cent. on the rear, which in round figures comes out 8000 pounds a wheel; using an engine of 4.875 inches by six inches, four cylinders, which will develop 47 horsepower at 1000 revolutions per minute; reduction in first gear 3.77:1, and a ratio of 8:1 in the axle; the diameter of the propeller shaft 1.5 inches; diameter of pitch circle on worm three inches and diameter of rear wheels 40 inches.

The torsion moment in propeller shaft from the engine on low gear would equal

$$Mt = \frac{47 \times 63{,}000}{265} = 11{,}300 \text{ inch-pounds.}$$

The torsion moment in propeller shaft from road wheels equals

$$Mt = \frac{16{,}000 \times 20 \times .75}{8} = 30{,}000 \text{ inch-pounds.}$$

$$\text{Stress in propeller shaft from engine} = \frac{11{,}300 \times 5}{1\tfrac{1}{2}^3} = 16{,}700 \text{ lbs. per sq. in.}$$

$$\text{Stress in propeller shaft from road wheels and propeller shaft brake locked} = \frac{30{,}000 \times 5}{1\tfrac{1}{2}^3} = 44{,}000 \text{ lbs. per sq. in.}$$

$$\text{Tangential pressure on teeth} = \frac{11{,}300}{1.5} = 7420 \text{ lbs. on low gear.}$$

$$\text{Tangential pressure on teeth} = \frac{30{,}000}{1.5} = 20{,}000 \text{ lbs. from locked wheels.}$$

Of course the question might be brought up that under this load of 20,000 pounds there is no motion, the wheels being locked, but in mountainous country I think you will agree with me, it is quite customary for a man to slide his wheels intermittently, and I am sure we can have considerable speed between the surfaces in contact and pressure very close to this. Many follow this construction in England at the present time, and it would be interesting to have our English friends' views on the subject. Where this design is used it undoubtedly speaks volumes for the dependability of worm gears as applied to heavy vehicles, considering they may be subjected to pressures from three to four times more than in the case of the double-brakes-on-the-rear-wheels construction. The high stress in the propeller shaft is quite easy to take care of, but it is mighty hard on joints, differential gears and bearings.

The above discussion may be radical, but will seem quite in order to anyone who has handled an overloaded car in mountainous country, where an amateur will declutch and roll backwards for a considerable distance and then apply the brakes violently. An observer watching the manipulation of a robust jackshaft or propeller shaft brake, coupled with a fierce clutch on a 25 per cent. grade, and the weight thrown on the rear wheel—as much as 80 per cent.—is led to surmise that the only logical design to stand abnormal shocks is the one involving the minimum number of parts subjected to the strains. To see a six-ton machine under these conditions is an event not easily forgotten by any designer; words are inadequate to express the frightful abuse machines have to stand under the conditions enumerated.

STEAM OMNIBUSES.

The paper by Thomas Clarkson of the Institution of Automobile Engineers on "Steam Omnibuses" was as follows:

In order to avoid misconception with respect to my attitude toward the internal combustion motor using spirit fuel, permit me at the outset to state that I fully appreciate the enormous utility of this type of motor in certain departments of automobilism—that my strictures upon it as applied to 'bus work should not be regarded as the outcome of a prejudiced judgment, but rather as an impartial scientific analysis of the special conditions applicable to 'bus work and heavier automobilism. This to the end that other fuels besides spirit should be utilized, such as kerosene, crude oil, coal, or coke, thereby easing the demands upon the spirit motor and its fuel supply, and leaving it greater freedom of development along its special lines of utility.

Increased facilities for passenger transport in cities are constantly in demand. Transport by electric rail motors, both on the surface and under ground has, to some extent, met this demand. But the automobile public service car, or as it is generally called, the motor 'bus, has already demonstrated its superiority over the rail car or tram.

The main points in favor of the 'bus over the rail car are its flexibility and independence of action. Flexibility is the dominant feature, flexibility of route, both as to deviations, extensions and modifications according to traffic conditions, and also flexibility of control in traffic, especially rapid flexibility of speed so as to accelerate promptly in response to traffic conditions whether congested or otherwise.

Complete flexibility is obviously impossible so long as the motors are dependent upon an extraneous power station. The vehicles must be self-contained and the power generated from within. Flexibility I regard as the keystone to the successful solution of the street traffic problem in cities, and I submit that the type of motor which gives most flexibility with the least trouble and expense is the type which will make good. Hence my preference for the steam motor 'bus in its present perfected form.

A properly constructed steam motor possesses a reserve of energy which is immediately available for a spurt, and acceleration can be speeded up smoothly and without jerk or inconvenience to the passengers. The control by the driver of a steam motor is simplified and the demands upon his energy and nerve force are reduced to a minimum. This last has an

important bearing upon the prevention of accidents and loss of life. The speed is entirely controlled by a foot throttle and no change gears are used.

The weight of a fully laden standard London 'bus is 13,440 pounds. The unladen weight is 7840 pounds. This is about 2000 pounds less than the former weights of both internal combustion and steam 'buses of the same carrying capacity (34 passengers) which were common a few years ago. This substantial reduction in weight has vastly improved the breed of the 'bus, for which thanks are due to the police authorities for insisting upon a lighter construction in order to obviate damage to adjacent properties consequent upon severe road vibrations. It was prophesied that this police demand would rule out the steam 'bus as it did the storage battery electric 'bus. But it is significant that the first 'bus to be licensed under the new regime as to weight was a steam 'bus; as a matter of fact a No. 5 National. This was nearly fours years ago.

I claim that the steam 'bus is still the best, the most efficient and popular, and this view is shared by some of the leading traffic men who control internal combustion motor 'buses. It is noteworthy that every one of the companies running internal combustion 'buses in London have been unable to stand the competition of their largest petrol omnibus rival, and have all been absorbed. Today the only omnibus company able to maintain its independence of the great omnibus combine in London is the company running steam omnibuses.

The advent of the motor omnibus appears to sound the death knell of the street rail car. The public shows a decided preference for the motor 'bus and the reason is not far to seek. The 'bus, owing to its greater freedom and flexibility of action, is easily able to beat the rail car in carrying passengers to their destination in the shortest possible time. Another advantage of the 'bus is that it can pick up and set down at the edge of a sidewalk instead of requiring passengers to walk in the roadway to or from the car. As a rival to the street rail car the motor omnibus has become a very serious proposition, and the perfected motor omnibus should be of immense value in solving the street traffic problem of cities. The presence of rails in the surface of a common road all automobilists will agree is detrimental to the efficiency of the road surface, and to the vehicles using the road.

The following summarized description will explain the leading points of the National steam 'bus: The fuel is kerosene, which is vaporized, mixed with air and burned beneath a water tube generator. The generator is entirely of steel and works at a pressure of 300 pounds (test pressure 1000 pounds). The generator is enclosed in a vertical cylindrical case under the bonnet of the chassis. The generator has a central drum which is closed at the lower end, and fitted at the upper end with a lid for cleaning. The drum is furnished outside with generating tubes of horseshoe form which permits free expansion without strain.

The steam is manufactured in four successive stages: (a) A preliminary heating of the water to about 140 degrees. (b) A secondary heating of the water under pressure to about 400 degrees. (c) Conversion of the heated water into steam at 300 pounds pressure. (d) Superheating of the steam to about 800 degrees.

The steam is utilized in a simple engine, two-cylinder double acting reversible, which drives the rear wheels of the chassis direct through worm gearing at a ratio of about 7:1. There is no clutch and no change gears.

The exhaust steam is condensed, filtered and returned to the tank for further use. The fuel consumption is regulated automatically by steam pressure. The success of the National steam 'buses is doubtless due in great measure to the excellent "fool proof" generator.

Time does not permit me to refer to the springing, steering, axle construction or brakes of the chassis, which are upon standard lines, but there is one detail of the construction of the National 'bus which calls for special notice, i. e., the wheel.

The life of a motor 'bus is extremely strenuous, probably the most strenuous of any automobile. Its annual mileage is about 30,000. Most of this is done on roads teeming with other traffic; consequently a 'bus has to stand hard knocks and rough usage. Wooden artillery wheels have proved unequal to the duty. Wheels constructed of cast steel have proved troublesome and uncertain. The National 'bus road wheel is constructed entirely of forged steel. The spokes are solid drawn tubes welded to a hub which is machined out of a solid forging. The outer ends of the spokes are welded to flanges which are afterwards machined before the rim is shrunk on. The perfect balance of this wheel and the reduction of about 170 pounds in the weight of the four wheels of a 'bus have materially reduced the wear on tires, and the absence of any internal stresses in the wheel is a great factor in reliability and public safety.

The proper lighting of a 'bus has been a troublesome problem, neither oil nor acetylene having proved satisfactory. Electric illumination gives best results. The problem has been to devise suitable electric equipment. This problem has been solved on the steam 'bus in a very simple and satisfactory manner. About 10 years ago I experimented with electric light for 'bus illumination. The first equipment was worked from a storage battery, but it did not pan out and electric lighting was discarded. Subsequently a scheme was devised whereby a small storage battery was used in combination with a special dynamo driven by the car and with cut-outs similar to lighting systems now used on some pleasure cars. After running this combination in service for several years I abandoned it in favor of a dynamo of the ordinary type directly attached to a small steam motor and without batteries or cut-outs. This steam motor runs at a constant speed of 900 revolutions per minute, and the equipment provides current for 150 candlepower a 'bus. The arrangement has proved completely satisfactory. The cost and weight of the installation have been reduced as well as the cost of maintenance; at the same time greater brilliancy of illumination has been secured. Excellence of illumination has proved a bull point in popularizing the steam 'bus and in helping traffic receipts.

Some steam 'buses of the earlier type have been in regular service for the past 10 years and are still running. But the steam 'bus of today has been evolved during the past two or three years since the designer and manufacturer took up the business of running 'buses and maintaining them.

In the short time available for this paper, it is impossible to give a history of the evolution of the modern steam 'bus upon which I have been engaged for nearly 20 years, and as the main object of this paper is to promote a discussion on the relative merits of steam and internal combustion 'buses, I will briefly summarize a comparison between these two types of motor.

The first cost of the 'bus appears to be about equal for the same quality of material and workmanship and with a similar rate of production.

Cost of maintenance—It has so far been impossible to obtain figures which are strictly comparable as to the relative maintenance costs of the two systems. The only way to obtain them would be for the same auditors to examine and analyze the books of both a steam 'bus and an internal combustion 'bus company, and to treat both in precisely the same manner as to depreciation, annual overhaul, establishment expenses, etc. Experience shows that the steam 'bus is in the garage for maintenance a much shorter time than its rival. It is the practise to withdraw an internal combustion 'bus from service one whole day in 10 for maintenance, apart from the withdrawal from service for annual overhaul which usually takes about two weeks. On an average during the year the internal combustion 'bus loses more than 15 per cent. of its total possible mileage. Total possible mileage means every 'bus that is licensed doing every journey every day for seven days a week throughout the year. During the year ended Oct. 31, 1912, the National steam 'buses, lost only 2.847 per cent. of the total possible mileage, and of this only .877 per cent. was due to mechanical failure. That it has been possible to run steam 'buses under the extremely strenuous conditions prevailing in London so as to give over 97 per cent. of their total possible mileage, whereas the internal combustion 'bus is not able to do 85 per cent., speaks eloquently both for the superior reliability of the steam 'bus and its cheaper maintenance.

Tires—There is less wear on tires with the steam 'bus owing to the smooth drive.

Rapid and smooth acceleration—In this respect the steam 'bus is easily demonstrated a winner. The extra steam pressure which accumulates at each stop gives an extra "push off" at restarting.

Flexibility and speed—In this respect also the superiority of the steam 'bus is demonstrated daily.

Illumination—The steam 'bus is admittedly the most perfectly illuminated.

Popularity—The public shows decided preference for the steam 'bus.

Vibration and jerk—There is less vibration on the steam 'bus. The engine does not run when the 'bus is stationary for picking up or setting down passengers, and there is no uncomfortable jerk at starting.

Depreciation—Steam 'buses which I started in regular public service over nine years ago are still running. I cannot find any internal combustion 'buses which have been in service so long. My rule for estimating depreciation is to give a six years' life, and at each annual overhaul to bring the 'bus right up to date.

Fuel—A steam 'bus uses kerosene fuel and so helps to relieve the pressure on the spirit market. With equality of ratio between

$$\frac{\text{price of kerosene}}{\text{price of spirit}} \quad \text{and} \quad \frac{\text{mileage on kerosene}}{\text{mileage on spirit}}$$

there is nothing to choose between either type in cost of fuel. The great increase in the demand for spirit and the absence of a like increase in the demand for kerosene favors the kerosene fired steam 'bus.

Drivers prefer the steam 'bus on account of less fatigue in operation and greater certainty of completing the journeys. Drivers are paid by the journey.

I will conclude the summary by giving the actual figures for lost mileage from all causes during the year ended Oct. 31, 1912, for the fleet of National steam 'buses in London.

'Buses withdrawn from service for annual overhaul	1.844%
'Buses withdrawn from service for passing drivers	.045%
'Buses withdrawn from service for police stops	.023%
'Buses withdrawn from service as a result of accidents	.058%
'Buses withdrawn from service in consequence of mechanical failure	.877%
Total, from all causes	2.847%

I think it will be agreed that these figures are remarkable, especially in view of the fact that the loss of service due to mechanical failure was well under one per cent., having regard to the exceptionally severe conditions of the service. During the above period over 15,000,000 passengers were carried on the steam 'buses.

It must be obvious that a steam motor which gives such results, under the abnormally severe conditions of public omnibus service, should have useful work to do in other departments of commercial automobilism, say for net loads of three tons and over. And it is important to note that for this work the steam motor can use coal or even coke fuel. In this manner a large section of commercial automobilism can be placed right out-

side the range of the oil trusts which now dominate the fuel supply, and commercial transport of first class reliability can thus be supplied at a lower working cost than is possible under present conditions with the internal combustion motor.

LUBRICATING OIL.

The paper read by Harry Tipper on "Lubricating Oil" was in part as follows:

Lubrication, of course, has for its one general object the conservation of power, or to put it another way, the reduction of frictional waste. The amount of lubricating oil used in the running of any machinery is so small that it has probably been neglected in favor of operations which involve much larger sums in the aggregate. A little study of the losses due to friction which occur in the moving equipment of any plant is sufficient, however, to show the enormous possibilities for the conservation of power and the reduction of waste, which lie in the examination of the conditions affecting lubrication and the quality necessary to meet it.

In practical use the oil must vary according to the speed, pressure and heat conditions in the equipment, the amount of moisture, the mechanical arrangements for oiling, together with the question of settlement and filtration. Innumerable modifications may be necessary in the grade of oil required; for instance, the question of dry and wet steam in the cylinders of a steam engine, superheated steam, character of circulating systems, the fit and finish of bearings, etc., all exercise a modifying influence upon the oils which can be used. The accuracy with which the mechanical conditions are determined and the extent to which the manufacturer and his engineering corps are experienced, in the consequent requirements of oils to meet such conditions, are the bases for the successful solution of lubricating problems.

On account of the lack of study which has been apparent on this question, and also partly on account of the rapid extension in the number of fields from which oil is produced, and the better possibilities for comparison in that regard today, it is possible to consider some of the usual methods of determining the lubricating qualities of oils and show wherein they fail of giving any indications of the practical value of such oils under the conditions in which they are to be used.

The common method of specifying lubricating oil which has been in use for a great many years is to stipulate a certain gravity, flash, fire, viscosity and cold test, under the assumption, of course, that such limitations of the tests mentioned will have the effect of obliging the manufacturer to submit an oil which will do the work to the best advantage. A thorough examination of these tests, however, shows that they are not by any means conclusive of the value of an oil for lubricating purposes. In regard to some of them the results are entirely misleading. The reason, of course, is easily determined. Some 20 years ago when practically all the oil which was in general use for lubricating purposes was drawn from Pennsylvania and adjacent fields, and was composed of practically the same hydrocarbon compounds with the same arrangements and was refined under much the same conditions, it was possible to compare two lubricating oils produced under these conditions by the arbitrary tests mentioned above, which were used by the refiner for his own convenience in measuring the uniformity and character of his runs. But the situation is entirely different. The fields from which the oil was drawn principally in those days supply only a very small percentage of the oil which is used today. The newer fields do not always deliver crude oil of the same characteristics either in a chemical or a physical way, and as a consequence these arbitrary tests no longer answer the purpose, as the different chemical and physical construction of the oils is sufficient to make any comparison on the same basis impossible. To put it briefly, such specifications are out-of-date. In the last 20 years new discoveries have been just as frequent in the oil business as in any other industry. New requirements have been imposed upon the oil refiner, owing to changing conditions in the equipment to be lubricated. It is consequently absurd to expect specifications which were permissible 20 years ago, under entirely different conditions, to be of any value to the buyer of lubricating oil today under new requirements and new possibilities.

Taking these tests in detail, let us examine the question of gravity in respect of the present day conditions. Gravity is simply the weight of the liquid in terms of weight of water. * * * The gravity reading is practically of no value to anybody but the refiner, who can and must use it in comparing the uniformity of his runs from the same crude. It has been proved through the gasolines, naphthas and burning oils that it has no relation to their value for use, and in the last two or three years the same feature has been thoroughly investigated and proved in respect of lubricating oils.

The flash and fire tests are represented respectively by the temperature at which oil, being heated at a standard rate, with a standard flame, passed over it at a standard distance, will show a flash or flame from the gases arising from its surface, and the point at which the oil under the same conditions begins to burn. From the standpoint of lubrication, the only bearing which the flash and fire tests have upon the oil under service, is to insure against the presence of volatile constituents which might begin to vaporize at the temperatures reached in ordinary work.

The viscosity of an oil has a considerable bearing upon its value for lubricating purposes, as it determines the speed of flow of the oil under certain temperature conditions, and it is obvious that the rate of flow of the oil is of great importance in considering conditions of pressure and speed in connection with all ordinary lubricating work. The trouble with the viscosity specification as it is used at present arises from the fact that the viscosity depends upon the temperature at which the oil will work, and if this temperature varies considerably from the standard temperatures at which the tests are usually made, there will necessarily be a great deal of difference in the usual working of the oil under the practical conditions involved.

The cold test is of importance as demonstrating the ability of lubricating oil to remain fluid under conditions of exposure to low temperatures. Its value, however, depends entirely upon the work to which the oil is to be put.

The point, however, which should be noted in connection with all these tests on specifications for oils is that they do not demonstrate the value of the oil under practical conditions, and merely put a limit upon the competition which can be secured or upon the amount of oil which can be drawn from for use without in any way furthering the value or advantage. To put this matter concretely, engine oils manufactured from different crudes show the following variations in the characteristics:

Gravity	19° to 31°
Flash	320° to 400°
Fire	370° to 450°
Cold	0° to 30°
Viscosity (on Saybolt instrument)	120° to 750°

or higher at 100° Fahrenheit.

Within this range of characteristics oil suitable for all classes of engines can be picked out, and the question of their suitability would not depend upon the particular test displayed by the oil. Two oils answering the same laboratory tests might show entirely different results in actual work, due to difference in the methods of manufacture not appreciable in a laboratory inspection; one would lubricate and the other would not.

Inasmuch as the arbitrary tests to determine the physical characteristics of the oil do not illuminate its value for any particular purpose, let consider what the oil should do. In order to bring this directly to the point of greatest interest to the society, that is, the lubrication of the motor of automobiles, let me suggest the requirements which a lubricant for this purpose should meet:

1. The oil should possess a sufficient body to keep the bearing surfaces apart at the temperature at which the bearings run.
2. It should possess such qualities as will reduce the friction to a minimum.
3. The flash point should be sufficiently high to insure against the presence of volatile constituents.
4. It should remain fluid at such low temperatures as will be met in service conditions.
5. It should have no tendency to decompose or to form such deposits as will gum up the machine and increase the friction, where the object is to decrease it.
6. It should contain no ingredients which will corrode or pit the metal.

In considering the qualifications to be added to these general requirements in order to define application to the mechanical conditions of cylinder lubrication, it is necessary to consider the questions involved in the operation of an internal combustion engine, which are different from those of any other type. What I have to say now may appear very elementary from a mechanical standpoint, but unless it is mentioned, the important bearing which it has upon lubrication will not be as obvious as I want to make it. After a charge has been taken into the cylinder on the suction stroke it is compressed to form 50 to 75 pounds before being fired. Naturally upon the starting of the compression stroke there is a tendency for the gasoline mixture to leak. There are two ways of obviating this difficulty, of securing full compression. These two ways might be stated as mechanically secured compression, formed by the close fit between the piston or piston rings and the cylinder wall; or compression secured by liquid seal, which means the use of an easy clearance between the piston rings and the cylinder wall and the sealing of the space between them by the use of a proper kind of lubricating oil. In respect to the mechanically secured compression the following points are worth noting as axioms which must be taken into consideration in estimating the conditions:

1. The closer the fit, that is, the less the clearance between the piston and cylinder walls, the more the power absorbed in turning the engine over. In fact, it is possible to secure perfect compression in this way only by securing so tight a fit that the mechanism will not turn. Even in practise good compression can be secured only at the sacrifice of some of the effective power.
2. The closer the mechanical fit between piston and cylinder walls the thinner a lubricating oil which will work its way between them. The thinner the lubricating oil the greater will be the wear and tear, because of the impossibility of keeping the metal surfaces apart where the clearances are so small and the lubricant must be such a slight film.

With these conditions, when wear and tear has once begun, every stroke of the engine increases the loss of compression, the consumption of lubricating oil, the consumption of gasoline, in proportion to the amount of power, and, in fact, decreases continually the efficiency of the motor. You will readily see the impossibility of securing and maintaining maximum efficiency under the conditions.

(Continued on Page 482.)

MARMON 1500-POUND DELIVERY WAGON.

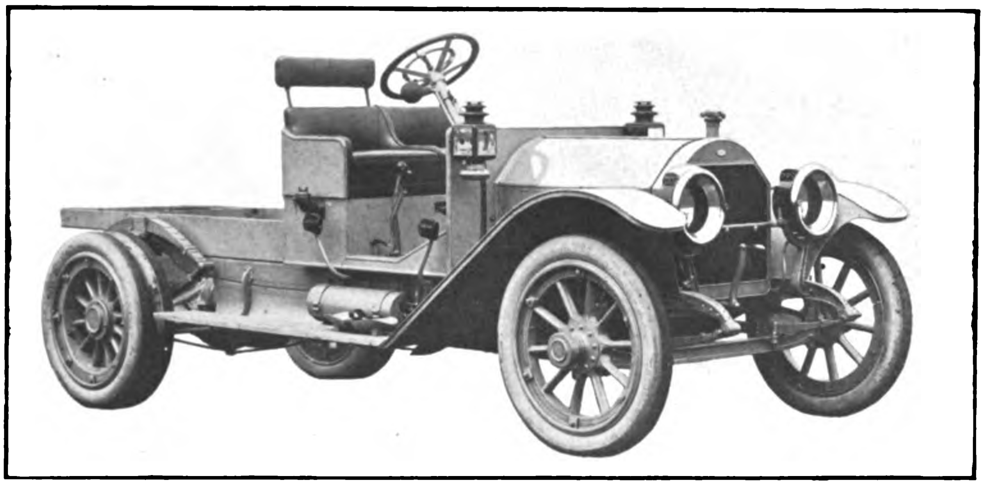
THE Marmon delivery wagon of 1500 pounds capacity, built by the Nordyke & Marmon Company, Indianapolis, Ind., is placed in the market with the assurance of the maker that it has been developed for the service for which it is adapted with more than usual care. The company has built pleasure vehicles for years, and has been engaged in machine manufacturing for three generations, an experience that is reflected in the Marmon passenger cars and is quite as noticeable in the delivery wagon.

The Marmon wagon is not in any manner radical. In fact it accords with standard practise so far as principles are concerned, and examination will impress one with the proportions of all the members and the quality of workmanship. The materials are of high grade and the design has been worked out to secure a combination of simplicity, accessibility and endurance. All wearing parts have been made of generous size with means for compensating wear, and provision has been made for sufficient lubrication wherever surfaces have frictional contact.

The motor is typical of Marmon design and construction, but differs from the pleasure car engines in that it has a bore of four inches and stroke of five inches, the horsepower rating being 25.6 by the S. A. E. formula. It is a T head, four-cylinder, water-cooled construction, and it is maintained that it is built as heavy as is the average 40 horsepower machine. The water jacket is large and the valves and ports are designed to insure sufficient charges of fuel and complete scavenging of the cylinders. The crankcase is a barrel form without supporting arms, which shape makes for accessibility and permits work and attention with minimum labor on the water pump, magneto, carburetor, oil pump and the connections.

The lubrication system is positive and has been tested for years in the Marmon cars. The crankshaft is drilled and the oil is fed by a pump to the three main bearings into the crankshaft, then through the connecting rod bearings and through tubing on the connecting rods to the wristpin bearings. The flow is through a sight feed on the dash and a float gauge indicates the quantity of oil in the reservoir. The other moving parts of the motor are lubricated by splash and the oil thrown off by centrifugal force. The motor is suspended on the main frame of the chassis at three points and is so installed that there is a straight line of the shaft, giving the highest efficiency and least loss from friction, angularity of shaft, and other incidental causes. The motor is governed so that by the automatic control of a valve in the fuel intake a speed in excess of 20 miles an hour is never attained. The governor is enclosed and the cover may be sealed to prevent a change by the driver. The governor is driven from the inlet camshaft. The motor is fitted with an acetylene gas starter. The ignition is by a high-tension magneto and battery, a dual system using one set of spark plugs over the intake valves. There is a single coil with a lock installed on the dash. The carburetor is an automatic float feed type that may be adjusted from the dash. The motor is cooled by a circulation of water through a cellular radiator mounted in trunnions on the chassis frame, and radiation is promoted by a large fan driven by a flat belt carried on an adjustable bracket at the front of the engine. The motor is installed under the regulation hood of sheet metal with a centre section bolted to the radiator case and the dash.

The clutch is a cone with the wide face covered with asbestos fabric, with a series of springs beneath the facing to prevent harsh engagement, a construction that affords positive results and long endurance. The transmission gearset is a selective type sliding gear having three forward ratios and reverse, assembled with the differential in the rear axle assembly. The shafts are all mounted in ball bearings and the gears are very wide face. The rear axle is a full floating construction with a pressed steel trussed housing, the design being the Marmon standard, the wheels being carried on the ends of the housing and driven by shafts bolted to the outer flanges of the wheel hubs. The differential is heavy and is designed to have long endurance. It is accessible by the removal of the rear cover plate of the axle housing. The front axle is a forged steel I section with large steering knuckles with annular ball thrust bearings. The spindles are fitted with roller bearings.



The Marmon 1500-Pounds Capacity Delivery Wagon with Open Express Body Equipment.

The frame is a pressed steel channel section with heavy cross members, well reinforced with gussets. The forward springs are semi-elliptic, 36 inches length and two inches width, and the rear springs are full elliptic, 38 inches length and two inches width. The

machine is driven from the right side by an 18-inch hand wheel through a gear of the irreversible worm and nut type. The tail lever and the drag link and tierod are liberal in size and are special heat treated forgings. Spring cushioned ball joints protect the gear from road shocks. The tiebar and the connections are behind the axle to afford protection. The control of the ignition and fuel supply is by levers mounted on a quadrant on the steering wheel. There is a foot accelerator. The left pedal operates the clutch and the right pedal the service brake. The gearset changes are made by a hand lever that is operated in an H slotted quadrant. The brakes are an expanding type operating within pressed steel drums on the rear wheels. The brake shoes are 16 inches diameter and two inches width, there being a total of 403 square inches of braking surface, and are made of alternate segments of asbestos fabric and a composition metal. The brake shoes are interchangeable and their operating mechanism is protected, but adjustment is easily made. The wheels are of wood, artillery type, 34 inches diameter, and are shod with 34 by four-inch solid or pneumatic single tires forward and single or dual tires rear. The rims are quick detachable demountable.

HARRIS OILS PROTECTED.

United States Courts Enjoin the Use of Patented Name by Two Western Concerns.

The A. W. Harris Oil Company, Providence, R. I., has secured two perpetual injunctions that prohibit the use of the name Harris in connection with lubricants offered for sale that would create the impression that these were the products of that company, the first against the Parker Refining Company, and the second against James C. Harris of Muncie, Ind.

The petition for injunction against the Parker Refining Company was presented to the United States district court for Ohio and this set forth that the petitioner had used the name Harris in connection with the distribution of oil since 1885, that the name was registered in the United States patent office, and that its business reputation was built on the public knowledge of Harris oils. Judge William L. Day in this case made decree that the registration of the name was good and valid at law and that the Parker Refining Company had infringed upon the exclusive rights of the A. W. Harris Oil Company, and issued a perpetual injunction prohibiting the Parker Refining Company from using the name Harris in connection with the sale of oils, and from its use in advertisements or upon labels, or the use of any word of similar sound or appearance.

In the United States district court for Indiana Judge Albert R. Anderson decided that James C. Harris of Muncie, Ind., doing business as the Harris Oil Company, had improperly used the name Harris without properly distinguishing it from the name of the complainant and that the defendant had copied advertisements of the complainant. He made decree perpetually enjoining James C. Harris, his agents or associates, from using the name Harris or Harris Oil Company in connection with the business of selling oils, or in advertisements, unless preceded by "James C." and followed by "of Muncie, Ind.," in the same size and style of type, and unless accompanied by some statement showing that the oils sold are not the original oils sold by the A. W. Harris Oil Company; from copying the advertisements of the A. W. Harris Oil Company, from using containers similar to those used by that company, from copying any of the distinctive designs of that company, and from offering to sell oil in any manner that might give the impression that it was the original Harris oil of the A. W. Harris Oil Company.

SEPARATE ACCESSORY SHOW.

Manufacturers Considering Exclusive Display During the New York Exhibition.

The question of continuing exhibition in connection with the next annual show of automobile pleasure cars at Grand Central Palace, New York City (there will be no truck display in that city or Chicago next year), or of holding a separate exhibit at Madison Square Garden concurrently with the vehicle show, is now being considered by the executives of the Motor & Accessory Manufacturers. The proposition to be determined is whether or not the interests would be best conserved by a separate show. Should the exclusive display be decided upon for members and others engaged in the manufacture of similar products the motorcycle and motorcycle parts makers will be invited to participate. In such an event no automobile vehicles will be shown, and neither would there be exhibits of accessories, motors, parts, supplies, equipment, etc., at the Grand Central Palace show. There will be no change, however, with reference to the Chicago exposition, and the members of the Motor & Accessory Manufacturers will show in connection with the exhibition of vehicles at the pleasure car exhibit. The Motor & Accessory Manufacturers now has an option on Madison Square Garden for a show, and will continue this until a decision is reached.

The H. J. Koehler Sporting Goods Company, maker of the Koehler delivery wagon, has produced a second model or type, the principal change being the use of 36-inch diameter artillery wheels fitted with demountable rims instead of the 48-inch rear wheels which was the original equipment. The new machine is also equipped with a standard automatic float feed carburetor, a Bosch magneto and other similar high grade auxiliaries and accessories. The original type of wagons, with 48-inch rear wheels and two-inch tires, will be continued, with some refinements.

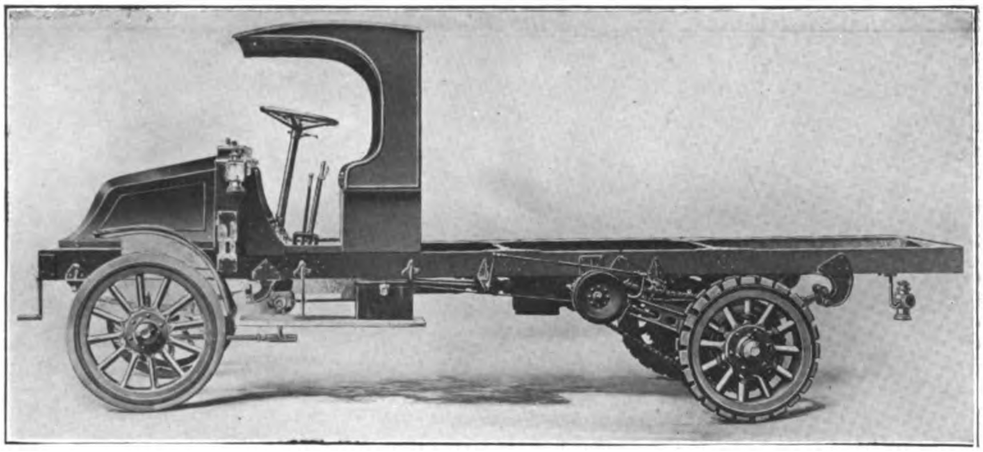
THE WILLET TWO-TON WAGON.

THE Willet Engine & Truck Company, Buffalo, N. Y., is building a two-ton delivery wagon, the first of a series of sizes that it purposes to produce. The machine has been carefully developed and it is maintained that it has unusual simplicity, extreme endurance and the working parts have been so greatly reduced that the care and attention has been minimized. The two-stroke cycle type of engine has been adopted, and this is a special construction that has features not to be found in any other. The design has been patented and it is the exclusive property of the Willet company.

The engine differs from conventional two-stroke cycle motors in that rotary intake valves are used, it being claimed that these valves are self-grinding and self-adjusting and require practically no attention. The design of the motor is unusual from several points of view. The cylinders are cast en bloc with the cylinders separate from the water jacket to the base flange. The head of the block is cast separate, this being cored for a generous water space. In the block the water jacket is open the full length and width of the casting, the spaces being very large. This construction permits clearing the water jacket of every obstruction, affording perfectly free circulation.

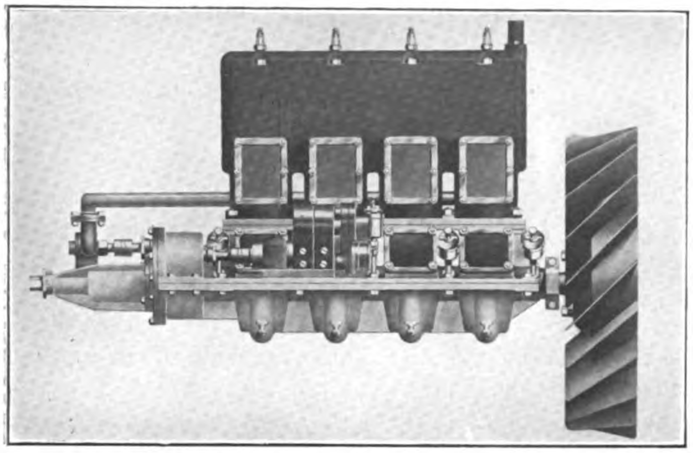
The head of the water jacket is a plate that is slightly crowned and it is retained by a series of cap screws. There is a single outlet at the extreme rear of the block. The exhaust manifold is cored into the block and it is covered with a ribbed plate, to which the exhaust pipe is coupled at the rear of the block. The water intake is at the base of the jacket, practically under the exhaust pipe connection. The base flange of the block is continuous and this is drilled for bolts at the ends and between each cylinder at either side. The engine base is in three sections, the upper and lower halves and an extension that covers the forward end of the crankshaft and forms a cover for the timing gears. In the upper section are large plates covering handholes through which main and crankpin bearings may be examined or adjusted. The lower section is formed to have four transverse channels or pits into which the big ends of the connecting rods swing, and which take the drainage of lubricant from the interior of the engine case. Large flanges are at either side of the case, which materially stiffen it.

The bore of the cylinders is 4.5 inches and the stroke is five inches. The engine is rated by the maker at 32 horsepower, but the rating by the S. A. E. formula for a four-cycle engine is 32.4, and if the usual 50 per cent. is added this gives a total of 48.6. The crankshaft is a steel drop forging, case hardened and ground, 1.75 inches diameter, and it is mounted in five bronze bearings, the front bearing being 3.625 inches length, the centre bearings 2.5 inches length, and the rear bearing 3.625 inches length, this giving a total bearing length of 14.75 inches. The crankpin bearings are two inches length. Each main bearing is lubricated by a grease cup. The forward extension of the crankshaft carries the timing sprockets from which the outside magneto and the pump and valve shafts are driven by silent chains. The valves are connected with the intake manifold and these will permit a predetermined volume of fuel to pass into the crankcase, where it is compressed and taken into the expansion chamber through the usual ports. These ports are covered with plates that may be removed should occasion require. The lubrication is by feeding the oil in the fuel in the proportions of one pint of lubricant to five gallons of gasoline. The fuel is carbureted by a carburetor that has fixed adjustment and in which there are no moving parts. The engine is cooled by a centrifugal pump of conventional type, the intake manifold being carried to the forward end of the motor and then back to the rear end. The radiator is a flat tube type that is mounted on springs on the main frame forward of the dash and is protected against damage and from the strains of chassis distortion. The ignition is by an Eisemann high-tension magneto. The motor is installed in the frame so that the lower section rests on the hangers, there being no strains on the bolts connecting the sections of the case.



The Chassis of the Willet Two-Ton Delivery Wagon, Standard Length, with Driver's Cab.

The clutch is a leather faced cone with a series of flat springs beneath the facing to insure ease in engagement. The drive is by shaft to the selective type Brown-Lipe transmission gearset, which is assembled as a unit with the jackshaft. The forward end of the gearset case is supported by a frame cross member, and the jackshaft is mounted with the outboard ends in heavy hangers. The gearset has three forward speed ratios and reverse. The shafts are heat treated nickel steel, and the gears, with inch faces, are heat



The Left Side of the Willet Two -Cycle Motor, Used in the Willet Wagons.

treated chrome nickel steel. The bearings of the gearset are Timken type, of large size. The drive from the jackshaft is by side chains.

The frame is a channel section of pressed steel, six inches width, and the cross members are large and reinforced by gusset plates. The front cross member is slightly curved and serves as a bumper. It is detachable and interchangeable, and may be quickly replaced if damaged. The springs are Krupp silico manganese steel, semi-elliptic, of extra length, and the bolts are very large and are hardened, ground and fitted with grease cups. The front and rear axle are Timken constructions, the front member being an I section and the rear rectangular, both being drop forged steel. These are fitted with adjustable roller bearings. The radius rods are swivelled and adjustable. The wheels are of wood, artillery type, and these are shod with 36 by four-inch single tires forward and 36 by 3.5 dual tires rear.

The drive is left side with the control levers in the centre. The steering gear is a worm and gear type. The usual pedals operate the clutch and the service brake and the hand levers control the gearset and the emergency brake. The service brake on the jackshaft drums is a contracting type, the drums being 10 inches diameter and two inches width, and the emergency brake shoes act on rear wheel drums 16 inches diameter and 2.5 inches width. The gasoline tank under the driver's seat has 30 gallons capacity. The wheelbase is 144 inches regular and 168 inches special construction, with 61 inches tread forward and 65 inches tread rear. The road clearance is 11 inches. The loading space of the standard body is 126 inches length for the regular machine and 144 inches for the special. The chassis frame is 39 inches width and on this bodies six feet inside measurement are installed. The chassis is fitted with a driver's cab with a bonnet extending over the dash. To this a windshield and curtains may be fitted if desired. The equipment includes the oil dash and tail lamps, horn, kit of tools and jack.

The purpose of the company is to produce different capacity vehicles which will have the same characteristics of that described, and will vary only with reference to the proportions of the components.

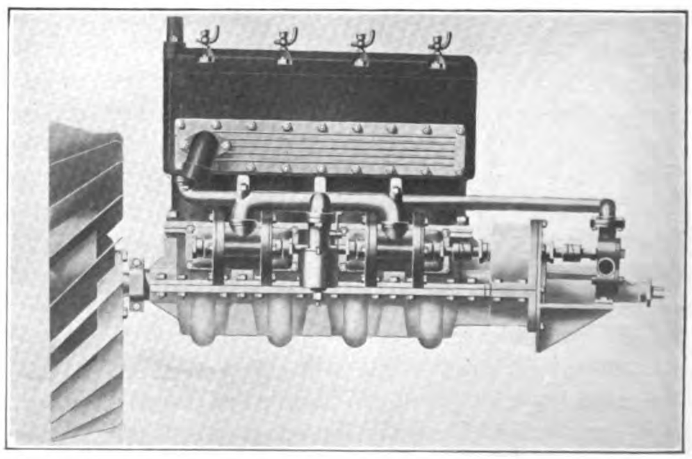
WOULD MOVE ARMY TRUCKS.

Col. E. T. Glenn Explains the Economy of Motor Transportation Over Railroads.

Col. E. T. Glenn of the Twenty-third Infantry Regiment, U. S. A., is an enthusiastic advocate of the government moving its armies by motor truck train instead of railroads, and he has given the subject much careful study. He proposed to the War Department last December that a regiment be moved from Indiana to San Francisco by a train of motor trucks, this to demonstrate the economy and the practicability of the proposition. The proposal was rejected as the War Department did not own sufficient machines.

Col. Glenn has not lost faith in the utility of the motor truck in army transportation, and he recently reviewed the subject before the officers of the Sixth Brigade and Second Division at the Sixth Brigade headquarters at Texas City, Tex., where the general value of the road train in army service was considered and discussed by a considerable number of army men. Col. Glenn has had the co-operation of a number of authorities in the collating of information and has developed plans for moving any number of men any desired distance. He maintains that it is practical to move a regiment of 2000 men across a country in 140 motor wagons at an expense of approximately $10 a mile, carrying 18 men to a vehicle and having a sufficient number of machines to carry the impedimenta. He believes in the mobility of the army carried by motor truck transports, and that there is decided advantage in being able to place a large body of infantry at a given point, not too far distant from the base, in the time that would ordinarily be required to make up and start a special train. Col. Glenn claims that motor truck transportation would cost about half the expense of using railroads. With such equipment an army would be practically independent of all the usual means of travel and communication.

Such truck trains would be practical for use under all conditions and would be extremely serviceable save in the event of quick mobilization at distant points, when railroads would be the most expeditious.



Right Side of the Willet Motor, Showing the Mechanism Operating the Rotary Valves.

WHITE TRACTOR IN LUMBER HAULAGE.

THE possibilities of power wagon use are seldom understood, even by those who have carefully studied the subject of transportation. Theoretically the motor wagon can only be used on highways, and the better results from every point of view obtain with the smooth and level road. Being constructed for operation on solid and comparatively even surfaces, there is no doubt that the greatest ratio of work and the largest economy will follow use where these conditions exist. The experience with the power vehicle has demonstrated that the better highway is imperative, and the use of machines designed for pleasure has educated the public generally to this requirement. That good roads are necessary for the realization of pleasure from the use of automobile vehicles has been so constantly emphasized that the public is now educated to the full value of perfected highways, and to maintain that power wagons can be worked where the ways are rough and unimproved, or where roads do not exist, appears to controvert every fact that has been impressed upon the people by experience and theory.

For years makers, owners and drivers of automobiles have sought to attract attention by using or driving machines where the conditions have been in reverse of what have been suited for legitimate use, but while such demonstrations may have established the endurance of a construction or the skill of the driver there is little probability that any person has been convinced that vehicles could be used under such circumstances for any length of time. Not only this, the cost of experiments of this character is generally so great that measured by any standard of publicity the actual return is exceedingly doubtful.

The use of the power wagon or truck is not necessarily confined to smooth highways or to the paved city street, but the mistake made by practically all who utilize machines on anything else than ideal ways is in neglecting to adapt the vehicles to the conditions of service. By this is meant that the truck or wagon, designed for work on the improved road, might be more economical were it adapted for the work to be done, but obviously the designer cannot produce special machines at the prices of stock productions, and the impracticability of building types that might be adapted for varying purposes is evident. Upon reflection there is little probability that any one will take issue with this statement. Those who consider the use of machines today are generally limited by the designs and constructions from which choice can be made, and instead of having just what can be worked to greatest advantage and economy as a rule endeavor is made to do work with what would be decidedly more efficient were it adapted for the express purpose.

An illustration of this statement is found in the use made of a five-ton White truck by a lumberman. The man is Theodor Kundtz of Cleveland, O., whose operations are carried on in the southern part of Cuyahoga county, that state, near the Brecksville station. The work that this man does differs somewhat from ordinary lumbering, where timber is cut and the land cleared indiscriminately, for his policy is to select trees that will yield the class of timber desired, to fell these and to haul the logs to the railroad station, whence they can be shipped to the customer. In other words, his business is furnishing special lumber, which is selected, cut and delivered.

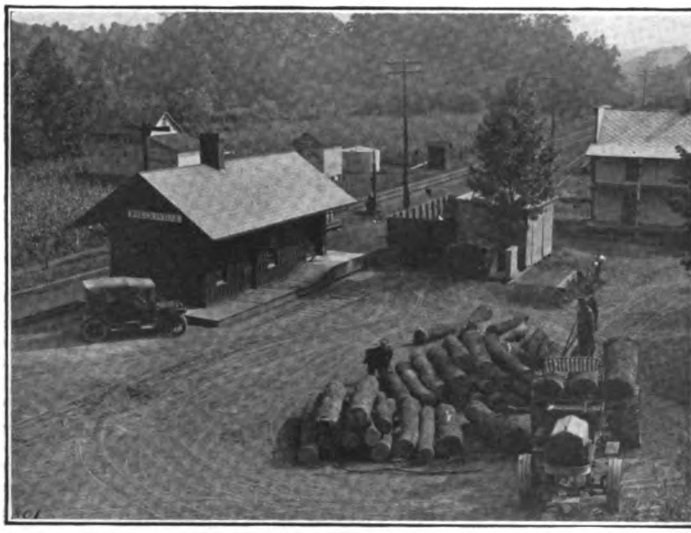
Hauling the First Log of a Load Onto the White Truck in Theodor Kundts's Timber Land.

Hoisting the Final Log of a Big Load with the Power Winch and Skid Poles.

Where it is possible to do so lumbering on a large scale is carried on near rivers, and generally in winter, so that the logs may be hauled with sledges on snow and piled on the banks so that they may be floated down the river with the high water of the spring. Sometimes industrial railways are built and the logs hauled by animals or small locomotives to the nearest river, and occasionally to railroad stations, and where the railroad is the means of transportation work can be carried on the entire year. Mr. Kundtz's business is not what would be considered large, but it

is of material proportions. He had used horses for a considerable period and he conceived the possibility of using a large truck to haul the logs from the forest to the railroad. He realized that it would not be practical to use a truck as built for road service, and he was uncertain what could be built for him. He consulted the engineers of the White company at Cleveland and stated to them the work he wanted to do and why he could not use a truck of the stock type.

The tractor engine might have been used, but such a machine must necessarily haul trailers, it is more difficult to handle in a forest because of the length, it is not as useful on the road, and with it the trailer must be loaded by manual labor. Mr. Kundtz wanted to have a single unit equipment that would have the power of the tractor and the mobility and usefulness of a truck, and while the machine he required cannot be compared with the logging train, the railroad was impossible for his purposes because of the peculiar character of his business. The log train would have large tonnage capacity, but it would be necessary to haul the logs to the track and load them, while he desired to have a truck that could be driven anywhere in the forest and loaded, this minimizing handling, and this machine could be driven on the roads, which would not be possible with a logging locomotive.



Unloading the Truck at the Log Pile at Brecksville, Six Miles from the Loading Point.

The White Truck Hauling a Six-Ton Load of Hardwood Timber Through the Forest to the Highway.

The engineering department of the White company began with a five-ton truck as a basis for development. Instead of the usual four-cylinder motor a six-cylinder engine was installed, this having great flexibility and abundant power, and the front member of the chassis frame was carried forward in semi-circular form to afford protection for the radiator and engine. Then special axles were built, for the front and rear wheels are special. The front wheels are the standard White cast steel construction, but they are fitted with steel tires which have a centre ring or flange that prevents side slip. The tires are wide, so as to be sufficiently supporting on soft ground. The rear wheels are the regular tractor type with 22-inch steel rims and round steel spokes that are mounted at either side of the wheel hub, where they are adjustable, and fitted to the rim a considerable distance apart. In the centre of the outer surface of the rim is a ring of steel, and from this at an angle of perhaps 20 degrees flat cleats extend to the edge of the rim, stiffening the rim and insuring traction on any surface. With the supporting rim width of 44 inches the truck may be driven with a full load over very soft ground. Of course the tread is much wider than that of the standard truck. The gear ratio is greatly reduced, so that the tractive effort is largely multiplied, and a load of six tons can be drawn over the ground in the woods without excessive strain upon the machine. The top speed is approximately eight miles an hour.

The truck or tractor is fitted with a power winch that is driven off the transmission gearset shaft, this being installed transversely and operated with a hand lever. This winch is really a necessity in handling the big logs, for with rope and chain tackle and skids 1000 feet of timber has been loaded in 20 minutes. Much of the wood handled is hard, such as oak, walnut, hickory and ash, and this is picked out and felled, sometimes in places almost inaccessible, where the truck must be driven with extreme care, especially when loaded. Timber of high grade, necessary for superior cabinet work, commands special prices, and wood that might not ordinarily be handled because of the difficulty of hauling is often a quality that is particularly desirable. Where timber is in ravines or in places where the truck cannot be driven close to it the winch and tackle can be used to haul it near enough to load, or the truck is hitched to tackle and the machine driven so as to haul the logs where they can be loaded. The work could be accomplished with horses or portable engines, but the cost would be very much increased.

Hauling from five to six tons for a load the truck makes trips between the forest and the Brecksville station that average about six miles. The loads are either piled close to the railroad siding or placed on

cars, the winch being used for raising the logs from the ground on skids or from the truck. With the truck a car can be quickly loaded, so that it has an efficiency that could be realized with no other equipment. The logs can be piled until cars are in readiness, so that the truck can be kept busy. After a year's service in all conditions the machine can be regarded as well tried, and it has been found equal to expectations in every way. The result from this special truck bears out the statement that when a machine has been adapted to meet unusual requirements it will have at least the same relative economy that it would have under the ordinary conditions of use.

COMPETING WITH RAILROAD.

Motor Truck Line Established to Serve Farmers Producing for Philadelphia Market.

The Diamond-Keystone Supply & Transportation Company, with a capital of $100,000, has been formed at Philadelphia, Penn., to operate a dozen or more motor trucks between Philadelphia and lower Delaware over the old King's highway, and transport the fresh fruits and vegetables, eggs, poultry and butter in less than a day from the small farms of Kent and Sussex counties to the city.

The idea is to deliver these fresh supplies early every morning to the green grocers and storekeepers direct, so that residents of Philadelphia can be served with fresh produce without the intervention of the middleman and the jobber or huckster. On the return trip of each of the five-ton trucks, freight and merchandise which the farmers do not produce themselves, will be carried south, thus lessening the cost of operations by getting revenue both going and coming. During the winter during every favorable hauling day, apples, celery, sweet potatoes, lettuce, eggs, poultry, pork, butter, etc., will be hauled.

William H. Saunders, a mechanical engineer, is a leading spirit in the venture. He conducted a farm in Sussex county and thoroughly investigated conditions. The concern will also agitate for the building of good roads. Heretofore there has been little if any competition with the Pennsylvania railroad's one line of transportation and farmers have habitually complained of losing their profits in freight rates.

The Muir shock shifter, the invention of an Englishman, by which a series of balls convert road shock into power, is being tried on a Velie truck.

ONE CHEESE A TRUCK LOAD.

Unique Demonstration Made in San Francisco Streets on Federal Machine.

The California Central Creameries specializes butter, cheese and dry milk, and recently as a demonstration of the possibilities a cheese weighing 1500 pounds was produced. Of course the only value of this enormous product was the public attention that it would attract, and just how to realize the fullest measure of publicity was a problem that was carefully considered. While exhibition at different places was logical enough, the main purpose was to bring to the knowledge of the people that this cheese had been made.

San Francisco, the largest city of the Pacific Coast, was the first place for display, and so the mammoth cheese was shipped there. Then it was placed on a Federal truck, and with the machine carrying signs and with the cheese stencilled in large characters, it was hauled through all of the streets in which the vehicle could be driven. The display was continued for several days, and then the cheese was shown in a store, where it was viewed by many thousands of people who had seen it on the wagon, or had learned of it through those who had seen it.

Federal One-Ton Wagon Carrying a 1500-Pound Cheese Through the Streets of San Francisco to Exploit High Grade Products.

An unusual use was made of a Reo two-ton wagon by A. F. Fifield of the Reo Sales Company, St. Catharines, Ont., who pulled down the walls of a brick barn on his property with grapplings and chains, the machine being a mechanical "Samson" for the occasion.

John N. Willys, president of the Willys-Overland Company, Garford Company and Gramm Motor Car Company, has appointed George W. Bennett vice president and general manager of these concerns. Mr. Bennett's headquarters is at Toledo, O.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

TAXING THE MOTOR WAGON.

Following the example in Massachusetts, inaugurated by the state highway commission, several states have this year proposed to tax the owners of motor service wagons for the use of the highways, this being based on the theory of a license issued by the state by the authority of assumed police power. But whatever the pretext, the proposition resolves itself into a means for increasing revenue. The conclusion is, apparently, that the owner of a freight automobile ought to be compelled to pay for the maintenance of the highway in addition to his regular contributions through taxation.

The highway authorities as a rule are in office through political preference. Taxation is a burden unless the other fellow pays for it. Logically it is practical to impose a heavy registration tax, especially if the opinion of the people can be based on a very general desire to escape from every possible form of tax. In Massachusetts an argument to limit the weight of the vehicles and load to 12 tons is the condition of the bridges, which are assumed to be too light in many instances. Unless controlled by the state the towns must maintain the bridges. To strengthen existing bridges and to build in future what will be adequate for the present needs of road transportation, the towns, the distinct beneficiaries through the use of vehicles carrying large loads, would tax all forms of motor wagons and deny the use of the highways to those which would be productive of the largest economy for those owning them. What has been attempted will be repeated in 1914 and the motor wagon interests of every character should organize for protection and force every candidate for the legislature to declare himself. In the event of failure to obtain such declaration the candidate should be defeated. The place to decide this proposition is at the polls.

SERVICE AND MAINTENANCE.

The selling organizations throughout the power vehicle market are making great efforts to impress upon the users and owners of machines and those studying the economies of such equipment the value of "service," and the relation it has to the economical use of all motor vehicles. The purpose is undoubtedly praiseworthy, but the result sought would be the better accomplished if "service" and "maintenance" were exactly defined. That is to say, if there were a precise knowledge of what constituted "service" and "maintenance" and each vehicle manufacturer, his representatives and agents, were bound by general acceptance to afford whatever was included in "service," and the owners would know just what they would have to pay for as "maintenance." Without a clear understanding of what is implied by either word there is no doubt uncertainty in the minds of thousands as to what they can justly expect from the manufacturers, and this being so there are those who assume they are discriminated against when they are denied what they may want, no matter what the claim. Without question there are those who honestly believe they are entitled to more than they receive; there are others who are satisfied with the attention given, while some claim as service practically everything that could be included in maintenance, and do so with a hope of getting something for nothing.

DRIVING UNLOADED MACHINES.

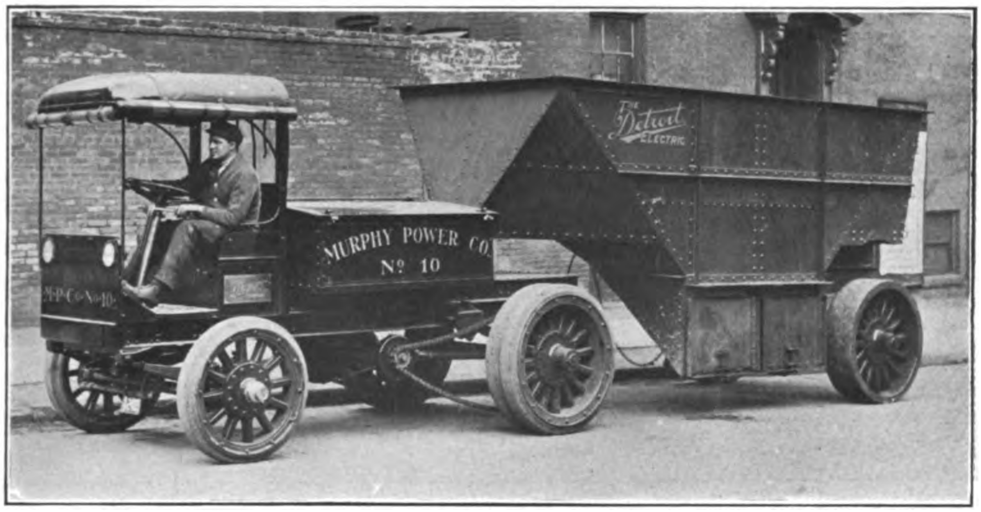
The owner of any motor wagon or truck should be certain how his machine is driven when unloaded. For the abuse of fast driving when light, and when the vehicle may be subjected to the extreme stresses of road shock, the driver is generally, if not always responsible, in like proportion to the owner who permits overloading. The machine may be driven well toward its limit when the road surfacing is smooth, but when on block or similar paving the pace should be minimum. The mistake is usually made of pounding a vehicle over rough highway, when as a matter of fact there is frequently distinct loss of time in loading and unloading. While there is no doubt of the wisdom of keeping a motor wagon moving, the speed should be made by those operating it—in reducing the standing or idle time to the lowest point practicable. How this may best be accomplished may be a problem of considerable proportions, but when once worked out the saving is continuous and, better than all else, the service is improved.

ELECTRIC COAL TRACTOR.

Twelve Tons of Fuel Hauled at a Load by a Detroit Industrial Equipment.

The economy of large load haulage impelled the Murphy Power Company, Detroit, Mich., to install an electric tractor and trailer to transport coal from the yards of the concerns supplying it to the plant of the company. The proposition was to haul as large loads as was practical, and, because it was proposed to utilize electric power, to have such trailer body equipment that there would be a minimum of time required for loading and unloading. The requirements were made known to the Anderson Electric Car Company and a tractor was designed by the engineering department which was approved and constructed.

As will be noted from the accompanying illustrations the tractor does not differ generally from the design of Detroit vehicles, other than that the chassis is short and jackshaft is carried very low, the jackshaft sprockets being very nearly, if not quite, on a line with the rear axle. The rear axle is heavy and the rear wheels are large. The short chassis and the position of the motor and jackshaft necessitated the location of the battery box in the chassis frame, the covers of the box being slightly inclined to insure drainage. The forward end of the body of the trailer is coupled on a pivot at the rear of the tractor chassis. The body is designed for gravity discharge from one or two side gates, and the form is such that the coal will settle to these gates as the body is emptied. The body is constructed of steel plates and angles, being reinforced wherever necessary. The trailer wheels are shod with wide steel tires and the tread is wide to insure stability, because of the unusual height of the body. The capacity of the trailer is 12 tons when fully loaded.



Twelve-Ton Detroit Electric Tractor, Built for the Murphy Power Company, Detroit, Mich.

ELECTRIC TRUCK IN ARSENAL.

Driven 35 Miles Daily in the United States Magazines at Frankford, Penn.

In the United States arsenal at Frankford, Penn., a one-ton G. M. C. electric wagon, a driver and two men are now doing a work for which three single horse wagons and 19 men were required. The men are paid an average of about $2 a day, and the cost of the electric current necessary to operate the machine, which is produced at the arsenal, is less than a cent a mile.

Previous to the acquisition of the electric wagon raw and finished material was transferred from the one department to another, some of these divisions being separate buildings, by hand trucks and horse wagons. This meant that the materials were collected in a building on a floor truck and drawn to a doorway, where a wagon was loaded. The load was taken to another building where it was removed and then distributed by the hand trucks. One driver was required for each wagon, and the other men loaded and unloaded the hand trucks and drew them about. The ammunition is packed in cases that weigh from 150 to 250 pounds, and this is largely the finished product of the arsenal.

As the electric wagon may be driven in the different buildings where ammunition is manufactured, provision was made to utilize it to the fullest extent by the construction of ramps or runways into the ground floors of the structures, and so the machine is driven into them, loaded and unloaded in quick time. The hauls are all short and the handling of the freight is expeditiously done, for the truck is not usually worked more than from 8 in the morning until 4:30 in the afternoon. The speed of the wagon is 11 miles an hour. The average expense for current has never been more than 30 cents daily.

It will be understood that the wagon has been made to take the place of the hand trucks formerly used, and that half the handling of raw and finished materials has been eliminated because of the safety of the machine. Figuring the saving of the wages of the men and the expense of the horses it is very evident that the electric will soon save its cost.

One of the large commercial motor vehicle orders that has been recorded in the industry this season has been received by the Knox Automobile Company, Springfield, Mass., from its San Francisco agent, the Reliance Automobile Company. This order is for six Knox-Martin tractors on a total contract for 15, which are to be delivered as fast as the factory can build them. Another order for two 10-ton tractors has been received from Sacramento, Cal. The company ordering the 15 machines will operate them in the oil fields, where Knox-Martin tractors have attracted attention.

NEW ENGLAND ELECTRIC MEN CONVENE.

Central Station, Vehicle Manufacturing and Allied Interests Meet to Promote the Systematic Development of a Field Unequalled in America--Co-Operation to Insure Service and Practical Exploitation Results.

THE New England convention of Central Stations, Electric Vehicle Manufacturers and Allied Interests, arranged by the New England Section of the Electric Vehicle Association of America and the Electric Motor Car Club of Boston, held at the Engineers' Club, Boston, Mass., May 20-21, was the first gathering in the history of the motor vehicle industry where manufacturers and distributors and the producers of energy met for the purpose of generally promoting business and stimulating activities that will be productive of greater utilization of machines.

The Electric Motor Car Club of Boston is a very active and aggressive organization, and the officers and members have for two years systematically endeavored to educate the people of that city and vicinity to the economy and endurance of the electric wagons and trucks, and to the simplicity and luxury of the electric pleasure car. The New England Section of the Electric Vehicle Association of America includes practically the membership of the Boston organization, which is made up of central station representatives, branch managers and agents for manufacturers of machines, batteries, motors, electric devices, appliances, accessories and central stations, manufacturers, representatives, etc., outside of Boston.

Delegates to the New England Convention of Central Station, Manufacturing and Allied Interests at Boston.

The purpose of the convention was to bring together those not identified with or active in the association, who might profit through the greater use of machines, especially those who represented the central stations, for it is believed that with the realization by central station interests that there will be profit in the sale of current there will be such co-operation as will materially increase the use of electric vehicles.

The convention was held in three sessions, the first given over to the discussion of "Electric Vehicle Progress," the second to "Salesmanship and Service" and the third to "Advertising." At each of these pertinent papers were read, and these were followed by discussion, the intention of the officials of the convention being to obtain constructive suggestions and ideas that might be submitted to the executive committee of the New England Section and to the Electric Motor Car Club of Boston with a view of formulating policies and systematizing endeavors that would lead to positive and direct results.

The co-operation of the central stations with the manufacturers and agents for electric vehicles has been advocated by those who have given the subject careful study because it is believed that unless the central station, which is to profit by the sale of current to the user of electric machines, shall give such assistance as is practicable, those who might purchase vehicles would hesitate to do so. It has been maintained that logically each central station can use electric wagons and trucks for service and maintenance work, and that this use is justified because of the economy. Having legitimate and economic reasons for utilizing these machines, supplying current that might otherwise be non-productive, the central stations must necessarily have garaging facilities which could be made sufficiently large to give a public service. With a public garage, which could be handled with a comparatively small force of men, and with employees experienced with batteries, motors, etc., there would be a distinct source of profit because patronage would be impelled.

Perhaps the greatest handicap to a proposition of this character is the general desire of all managers to make a profit from money invested, when it would hardly be practical to make an electric garage profitable until a sufficient number of customers had been attracted and been taught by experience that the ma-

chines were given the service paid for. Undoubtedly a small organization can care for a garage of large proportions, and it is conservatively estimated that a man can secure a greater measure of economy by patronizing a public service if he has less than 10 vehicles. But a very small number of men can care for 50 or 60 wagons and cars. This being so the central station can, when a garage has been established, reduce the cost of maintaining its own transportation equipment materially, supply current without the construction of private installations, encourage the use of machines through practical care and attention, and develop a business that is certain to be continuously profitable. But like any other business that is primarily dependent upon the endeavors of those promoting it, profit can only come when customers have been attracted.

In New England there are a number of central station garages, among them being those at Boston, Hartford, Lowell, Salem, Worcester, with others in prospect at New Bedford, Springfield, and possibly other cities. These have been developed along different lines and policies, and the experiences of those conducting them are varied. The officials of these companies have had sufficient confidence in the future of electric machines to establish public service stations when making provision for their own transportation departments, and in each instance this has been followed by the increase of number of vehicles in use. The desire of the promoters of the convention was to bring together as many as possible of central station men, manufacturers and representatives, with a view of learning if possible a level on which all could co-operate and create an understanding as to the attitude of each with refence to the policies of the other.

The convention was undoubtedly productive of a great deal of good. More than 150 different delegates were present and there was a desire to discuss every proposition from every angle. The uncertainty of the commercial possibilities of New England brought forth the suggestion that two men be selected, both experienced with electrics, the one a pleasure car and the other a service wagon expert, who should visit every locality in the six states to make surveys as to local conditions, to ascertain definitely the facilities and attitude of the central station, and to carefully determine the probabilities for business, they to make report to the association, submitting the data for the benefit of any of the members who might care to utilize them. This suggestion was very generally approved. With the manufacturers the main problem is to learn where they may locate agents, and the central men are equally desirous of knowing how far the manufacturers will co-operate in the development of business.

Another question carefully considered was that of service, there being so wide a variance to the expectations of the users of vehicles, the builders of machines, the agents and the central stations, that the delegates wished to reach a reasonable definition of the term and differentiate it with maintenance. From all points of view there was agreement that the purchasers were entitled to care and attention, and the belief of the manufacturers was that the central stations ought to be willing to co-operate to the extent of inspecting vehicles, advising the users of them, and of making rates for current that would encourage and not discourage those owning machines. The central stations, however, were inclined to believe that the manufacturers of vehicles should not expect them to give some of the attention that would ordinarily be given by agents or branches because of the sale of current, but should contribute a definite amount of the purchase price of machines, for instance, that would compensate the stations for the expense of the service given.

May 20-21, Gathered at the Ball Field, Bass Point, Nahant, to Witness the Struggle for the Championship.

Those present agreed that service was the greatest and most potent factor in the promotion of the sale and use of electric machines. Wherever service could be given the machines increased in numbers and gave satisfaction. Where service is not afforded the reverse of this is true.

The convention was arranged by a committee made up of these committees: E. S. Mansfield, chairman; O. G. Draper, secretary. Entertainment, Day Baker, chairman; E. W. M. Bailey and D. C. Tiffany. Headquarters, Leavitt L. Edgar, chairman; Robert C. Gregg and Edmund H. Hewins. Programme, H. F. Thomson, chairman; E. R. Davenport, George W. Holden, Howard T. Sands and F. D. Stidham. Finance, Mor-

ton J. Fitch, chairman; J. A. Hunnewell, Fred M. Kimball, S. Fred Smith and Albert Weatherby. Invitation and attendance, Eugene Carpenter, chairman; F. W. Smith and John A. White. Review, Frank N. Phelps, chairman; E. D. Dodge, H. S. Knowlton and Frank J. Stone. Publicity, O. G. Draper, chairman; John F. Mahoney, Charles F. Marden, John D. Murphy, George L. Parker, Howard Reynolds, Charles F. Roberts, Frederick G. Roberts, James T. Sullivan and A. W. Talbot.

The morning of the first day from 10 was given over to registration and the reception of the delegates by the committee. The first session was begun at 1 in the afternoon, the company being called together by Chairman Mansfield, who announced the first subject and introduced Fred M. Kimball as the presiding officer of the convention. Mr. Kimball's introductory remarks were substantially as follows:

Chairman Kimball's Opening Address.

Gentlemen: I welcome you here on behalf of the New England Section of the Electric Vehicle Association of America and the Electric Motor Car Club of Boston, and trust you will find your attendance pleasant and profitable. We have met for wise deliberation and frank, full and friendly discussion of ways and means of promoting the scope and enlargement of the electric vehicle industry, the success of which means so much to us and to the people of our country. Very great progress in the introduction of the commercial vehicle, particularly, has been made during the past year, and there is every reason to expect still greater activity and progress during the coming year. It seems to me that among the more important objects of our activities are

First: An effort to popularize the electric vehicle with the small tradesman, the artisan and the family of moderate means, for the electric carriage is a vehicle for woman's use as much as for man's; to develop a demand that can be met by a standardized product that can be built in quantity and, therefore, at a cost which shall permit a selling price more comparable with that of the horse drawn equipment. I think you will probably agree with me that a greater number of commercial electric vehicles are "made" than are manufactured at present. More varied and widespread use of standardized types of vehicles and quantity production is the "key to success" in this particular direction. In this regard we can well take a leaf from the book of experience of our friends in the gas car business. Those who require heavy trucks and wagons, and those who require special construction, usually can and will pay a price commensurate with the cost of serving their needs, but the grocer, the laundryman, the butcher and the baker need simply a reliable, sturdy vehicle of moderate carrying capacity, at an initial cost and annual maintenance and operating charge within the reach of a pocket book none too plethoric. A business built up on the production and sale of vehicles of this character, however, when once established, dealing with large, continuous and duplicate production, can be made very attractive.

Second: Attention should be concentrated on providing a wider distribution of garage facilities which will be available to the class of customers referred to above. Garage service must be prompt, effective and honestly and fairly conducted. While the use of the mercury arc rectifier and the rotary rectifier has made it possible for the owner of a small pleasure or commercial vehicle to do his own charging, the owner of a commercial vehicle usually lacks the dispositon, the time, the knowledge and the means to adequately care for his battery and the inspection and up-keep of the vehicle itself during the first year's use at least. Improved garage facilities will do much to assist in enlarging sales of the types of vehicles required by tradesmen, and I am rather hopeful that by a suitable campaign of education, livery stable keepers may gradually be induced to add facilities for charging and garaging electric vehicles, so that ultimately adequate service may be found, even in all our smaller towns. Proprietors of livery stables must appreciate that the horseless vehicle has come to stay. It would seem to be part of wisdom for them to recognize the situation and meet the new demand half way. The electric carriage can be garaged and charged in buildings heretofore devoted to caring for horses, with substantially no changes or additions, and in this respect the stable keeper can much more easily provide for electric garaging than for garaging gas cars.

Third: To the central stations we must look for the most moderate rates they can safely adopt. Our larger city stations for the most part are already making rates which are attractive and helpful, but in the case of many of the smaller stations there is a lack of appreciation of the ultimate gain which will almost certainly succeed the apparent present loss. Rates are frequently held at a prohibitive figure, and only an indifferent service is provided.

Finally, we all—manufacturers, owners of garages and central station managers—must strive for economies in our business. Inefficiency of labor, the high cost of all material used in our industry and the deadly "overhead" charges, in particular, unite to make the problems of achieving popular prices for vehicles and service a most difficult one.

Day Baker, Treasurer, Electric Vehicle Association of America.

Fred M. Kimball, Chairman, Presiding Officer of the Convention.

Harvey Robinson, Secretary, Electric Vehicle Association of America.

Mr. Kimball then read a paper on "New England as an Electric Vehicle Field," which was retrospective, emphasizing that these states might properly be regarded as the birthplace of the modern electric conveyance, showing the part New England men and interests had taken in its development, calling attention to the possibilities for its use for pleasure and in industry, and pointing out that there were some special uses, such as milk and ice distribution, that were seemingly of very large promise.

The paper was briefly considered and then the second paper, "The Growing Popularity of Electrics," written by H. H. Rice of the Waverley Company, Indianapolis, Ind., was read by F. F. Rogers of New

York City. This paper was discussed to some length and it was followed by the paper of L. R. Wallis on "Central Station Service for the Owners of Electric Cars," which was taken up in the absence of W. C. Anderson, whose contribution to the programme was deferred until the evening session. This paper was as follows:

Central Station Service for the Owners of Electric Cars.

In the majority of cases the purchaser of his first electric of either type knows comparatively little about those essentials of operating, maintenance, care and charging, which it is necessary for him to understand in order to insure the successful operation and satisfactory performance of his battery driven machine. It, therefore, devolves upon some interested party to provide the information and render the service required for its intelligent installation and operation. The logical agencies for the undertaking of this work are the manufacturer or his representatives, the central station and the owner.

We will assume that the owner is willing to use what knowledge and facilities he may possess for the most efficient handling of his property, but he may rightfully look to the manufacturers from whom he purchases his car and equipment and the central station which supplies him with electric current for charging to co-operate in providing such service as is necessary to assist him in making his electric a success. From an electric motor car standpoint the interests and responsibilities of the manufacturer and central station are very closely allied and it becomes difficult to differentiate between the character of service that each should render as in many instances each interest stands ready to offer the electric car user service along practically the same line. Geographical and financial conditions often become instrumental in determining just where the line of responsibility should be drawn.

In the large cities where the manufacturers are ably represented and a strong central station company exists, the question of service should be of such a character that the methods employed would not need discussion as each interest will doubtless be willing to offer the user practically the same assistance. In smaller cities and towns where the central stations are not in a position to engage actively in promoting the electric vehicle, if the field is considered a promising one, the manufacturer should assume the larger part of the burden until the business grows to such an extent that the central station will be automatically forced into it, while in such territories as are remote from the factories and lack adequate factory representation, the central station should strain a point to foster the industry during the introductory period, after which the volume of business will warrant the manufacturers in establishing sales agencies and maintenance departments in those sections.

In any event there should be a tacit understanding between the manufacturer and central station as to what part of the service each is willing to assume and a compromise agreed upon covering such details not previously arranged for, so that the efficiency of the service will not suffer.

If a distinct line were to be drawn between the service to be rendered by the manufacturer and the central station it would appear to be equitable to make the division on the basis of instruction and supervision of that portion of the equipment supplied by each. According to this rule the manufacturer would advise as to the size and type of the machine to be purchased, the battery and motor equipment and other details necessary for the satisfactory performance of the work required, while the central station, if sufficiently informed, might properly act in an advisory capacity to approve the recommendations of the agent. The manufacturer should also have charge of the maintenance of the machines after they have entered service and direct the manner in which they should be charged and cared for.

The central station should deal with the customer in matters relative to the supply of charging current, the rate at which it is sold, the proper charging apparatus to be installed and in the capacity of a consulting engineer in case the operation of the electric should be unsatisfactory, or the cost of such operation should prove excessive. In justice to the user, however, in each case it should be clearly understood what portion of the service is gratuitous and what is to be charged for.

To be a bit more specific the selling agent of the manufacturer should seek out the prospect, bestow upon him the necessary time and attention and provide him with full information concerning his product; he should study his conditions and requirements in order to convince first himself and then the prospect whether or not the electric will satisfactorily perform the service required. If the results of the investigation are favorable to the electric he should put forward his best efforts to effect a sale. The central station should then be notified of the sale with full information as to name, address, type of machine, size of battery, etc. This is important in order that the central station may study the situation from its standpoint and be ready with service by the time the car arrives. On the arrival of the car the manufacturers' agent should instruct the owner or his driver to a full understanding of its construction, the most effective and efficient operation of the machine, the care necessary for its most successful performance and familiarize him with the care and charging of the battery necessary for its maximum life and mileage. He should provide regular inspections and arrange for speedy delivery of repair and renewal parts in case of necessity.

The central station on being advised of the sale of a car should at once get in touch with the purchaser for the purpose of learning his requirements and advise the best methods of caring for and charging his car either at a public garage or his own charging station. In case of the latter the lines should be run and the service installed. The central station should be in a position to recommend the best charging apparatus for his specific need and render assistance if desired in procuring and installing it in the customer's premises. The electric company should also provide instruction in the best methods of using such apparatus and the most economical manner of using the current. Regular inspection of the electrical apparatus should also be made to insure constant service, safety and satisfactory performance.

The central station should establish a rate for charging current which, while profitable to itself, should be low enough to meet the requirements of battery charging, realizing that this branch of its business requires service during the period of its valley load. Although the foregoing may be considered a legitimate division of responsibility between the manufacturer and central station, it is self-evident that the line should not be drawn too rigidly, as in many instances the two interests can work conjointly not only for the increase of sales, but for the betterment of the service and the greater satisfaction of the user.

Co-operation is the key note of success in the electric vehicle as well as in every other business and where the various agencies work in harmony there the best results will be obtained. The central station can well afford through advertising and publicity to educate the minds of the public along the lines of the superiority and advantages of the electric and thus augment the sales of the agent, and he in turn can easily increase the business of the central station by friendly advice to the purchaser and wisely designed sales.

The central station can render valuable service to the manufacturer as well as the user by maintaining a department of vehicle and battery engineering, whether it consists of one or more individuals whose function it is to bring the prospect and agent together for their mutual benefit and to safeguard the interests of each after the sale has become consummated. Service after the sale is of the utmost importance by whomever rendered and is the secret of the repeat order.

Another important feature of service which should be undertaken by the central station is the purchase and use of electric vehicles of both types, in its own transportation, to an extent warranted by the size of the company and character of its business. In this manner only can the central station obtain the data necessary to intelligently foster the interests of its customer. The moral effect of putting into practise the advice given to prospects cannot be thoughtlessly ignored. It is the province of the central station either to establish public charging stations under its own auspices or use its influence to induce others in its territory to open electric garages or add electric charging apparatus in an already established garage. The majority of the owners of passenger electrics and fleets of commercial electrics will desire to support their own charging facilities, but it is essential that public charging stations be available to provide boosts and render maintenance service when called upon to do so.

As a step in the right direction in anticipation of a more satisfactory arrangement, facilities should be arranged at the main power station where electrics may be charged at any time during the 24 hours. The subject of a public electric garage is one of the utmost importance during the introductory period of the electric vehicle, for without such an institution the agent finds it very difficult to interest his prospects, and even if a sale is made the owner passes through a very discouraging period of experimentation on account of the superficial knowledge possessed by those directly in charge of the machine.

In an increasing number of instances central stations have deemed it expedient to maintain public electric garages either in connection with their own fleets or under independent management at another location where owners may receive expert care and advice and there they may feel free to come in cases of unsatisfactory performance and unknown difficulties. There are few central stations of moderate size who cannot provide some such an arrangement and it will be found that the agents will centre their efforts on the territories which have been made possible in this manner. Whatever else the manufacturers may demand of the central stations they certainly have the right to expect a friendly attitude, co-operation and a warm welcome in the territory served by them.

There will probably be a wide difference of opinion as to the natural division of responsibility between the manufacturer and central station, but we must not lose sight of the fact that the two interests are in partnership for the purpose of supplying the maximum of service to the user with the minimum amount of friction between themselves. Service must be rendered—by whom the user is but slightly concerned, and if each factor in the business is willing to do just a little more than he considers his share no one need have any misgivings as to the future of the electric vehicle.

The conclusion of Mr. Wallis' paper was followed by discussion relative to service and what constituted it, and the value of the co-operation of the central station was set forth by J. C. Bartlett of the Woods Electric Garage, Philadelphia, Penn., who stated his experience with the Public Service Corporation of New Jersey in connection with the establishment of a ga-

rage at Camden, N. J., and who defined service and maintenance as afforded by his own business and the co-operation of the central station as productive of practical promotion. He demonstrated that both the central station and the garage had their responsibility to the owner of the vehicle, and where the obligation was understood and regarded the results were in every way satisfactory. Mr. Bartlett stated that while the line between the service and maintenance was clearly drawn in his business, it was a part of his policy to go even 300 miles away to give to customers the attention they were entitled to. Yet whatever was maintenance was charged as such.

Following the session the delegates gathered outside the club and saw a very large number of electric cars, wagons and trucks driven through Arlington street for their observation, the owners of machines in Boston instructing their drivers to make detour through the thoroughfare.

Constructive Criticism of the Electric Vehicle.

The evening session was begun at 7:30, at which time E. R. Davenport read a paper on "Constructive Criticism of the Electric Vehicle" (from the viewpoint of the outsider looking in.) Mr. Davenport was a very exacting critic and he maintained that the purpose was to encourage discussion and to formulate opinion that might be productive of beneficial results. Relative to manufacturing, the observation was that most builders of electric vehicles were so healthy industrially that they were not disposed to consider conditions they should; that the production was not as large as the size of the plants might lead one to believe; that the large capitalization, big overhead charges and small production necessitated a heavy fixed charge on each vehicle. To this must be added the manufacturing cost and the profit. In reply to the suggestion that if the central station co-operated with the manufacturer the producton would be increased, he maintained that if the manufacturer improved his service and the quality of his salesmen he could materially increase production without demanding so much from the central stations.

He urged that an electric pleasure car, to be sure, that could be sold for about $1250, would be immensely popular and would be bought in large numbers. He recalled that an electric runabout was sold about 10 years ago for $850 that was really very serviceable, and argued that electric vehicles were steadily increasing in price instead of decreasing, while gasoline car builders were decreasing the price or were adding to the equipment with no greater cost. Not only this, the gasoline makers are generally increasing production. He analyzed the cost of the components, concluded that an electric car should be built cheaply and maintained that the central stations were not unreasonable if they asked that the selling prices be reduced. With reference to service machines he did not regard the prices as high as those generally established for the pleasure cars, but believed there should be a radical change in the methods by which these were sold.

Turning to salesmanship he held that it was not wise to appoint a man in Boston agent for six New England states, for while such agency might be profitable the central station cannot be given the attention and co-operation necessary, especially if some distance from Boston. He gave illustrations to demonstrate the need of well trained salesmen, thoroughly informed relative to the machines they sell, who know the conditions in which these will be used, who understand the attitude of the central stations, who can analyze a haulage problem and present the facts in convincing manner, who can advise their customers and can influence business because they know all that a high class man should know. He gave attention to advertising, and pointed out that it was not sufficient to deluge an inquirer with literature, but there should be means for following up and developing the business. He commented on the character of advertising and rejected the artistic as against that which educated, that the electric is a utility and gives data and facts, and contended that the public wants experience data and information that it can prove; suggestions that talk the language of the different businesses, and service all the time.

With regard to service he believed that this was a term that should be well defined, so that there shall be no doubt as to what the manufacturer and agent shall provide, and when a vehicle has been sold attention should be given that will satisfy. How a customer should be taken care of should be clearly understood. He believed that the service responsibility should be shared by the manufacturer, the battery maker and the central station and that the obligation should not be shirked. No matter what the condtions the customer ought to be given a standard service by all three, and a thorough understanding of responsibility would no doubt bring about satisfactory attention and a united endeavor that would be in every way promotive of the use of electric machines. He did not assume how the service expense should be shared by the manufacturer, his agent, the battery maker and the central station, but believed this division was the ultimate solution of the problem. He believed that the service station, operated to give the best care possible to every make of car or service wagon in a given territory, no matter who provided the service or how the expense of it is to be divided, was the first essential to the permanent advancement and progress of the electric vehicle industry.

This paper was highly appreciated and it was followed by a paper on "How the Central Station Can Develop the Electric Vehicle Load," by W. C. Anderson, president of the Anderson Electric Car Company, Detroit. He said in substance:

How the Central Station Can Develop Electric Vehicle Load.

I should indeed be ungrateful if I did not avail myself at this time of the opportunity to publicly express my appreciation as well as that of my associates, at the splendid publicity work which has been done, and general co-operation by the Boston Edison Company in promoting the electric vehicle industry. Its management has been broad minded enough to see that the advent of the electric vehicle in large quantities in this city would effectively solve one of the most vexing problems which the central station has to meet, namely, a constant demand for their off-peak load.

An exclusive electric garage, which I understand, is of the

highest quality, is now being operated by the Boston Edison Company. This garage is fast assuming the characteristics of the ideal station, and will undoubtedly serve as a model to be followed by other central stations who will soon fall in line with this "help each other" progressive movement so general throughout our land.

Since Oct. 1, 1912, the power rates for charging electric vehicles in your city have been reduced more than 50 per cent. Prior to the date mentioned the consumer of current for battery charging paid $10 for 100 kilowatts. Now he may secure the same amount for about $4. The benefits of this reduction in power rates has already been felt by the Edison company in the large increase in power consumption which has followed. The electric vehicle industry has also been greatly benefited.

The Boston Edison Company has set the pace by purchasing and operating 56 electrically propelled vehicles. By this move material evidence is shown the merchants of this city that those of highest authority on electrical matters have put their stamp of approval on the modern electric vehicle. Further, the Edison company has appropriated generous sums for publicity work.

These acts are in strong contrast with the policy followed by some of the non-progressive central stations, who are still living in the dark ages, quite content to operate their business today along the same lines followed by their great grandfathers. There are too many central stations in the East whose managements do not realize that there is a larger profit to them in the electric car than there is in the old horse drawn equipment or gasoline cars. Would you believe, gentlemen, that there are localities within 50 miles of where I stand that are charging 25 cents a kilowatt for electric charging current. We receive many inquiries and personal calls at our Boston branch by those seeking information as to the cost of charging electric cars in certain localities, and upon learning the prohibitive rate they would have to pay the inquirers determine to postpone the purchase of electric cars, and thus sales are lost, resulting not only in loss to the electric vehicle manufacturer, but to the power station itself. Do you suppose that in such localities electric cars will ever be used to any extent under the present circumstances? I say no. There may be a few who care nothing for expenses who will invest, but the buying will never be general there until the central station does exactly what the Boston Edison Company has done, and what the New York and Chicago Edison companies are doing.

I cannot refrain from here mentioning the splendid work which has been started in New York by Mr. Arthur Williams, who has started a co-operative campaign in promotion of the electric vehicle, which substantially within the next few years will surely result in a benefit to his company.

In smaller cities the promotion of the electric vehicle industry by the central station will, of course, be on a smaller scale than in the larger cities. However, their central station manager should use his best influence and give his time to see that a responsible dealer in his city represents a line of electric cars of some standard make. He should offer every encouragement to such a dealer by not only advertising the merits of the electric vehicle in public advertisements, but also should purchase electric cars from him for the central power station work. Help him start his garage right by giving him the service of his engineers, and last, but not least, give him free power for several months until he gets his work built up to a paying basis. In my opinion the establishment of a responsible dealer who is capable and has the proper facilities for handling the electric vehicle business is the first step toward success. If such a dealer cannot be easily located in your city you should take hold of the proposition yourself until a representative of the proper caliber can be found.

We are constantly selling electric cars to owners of gasoline automobiles such as the Packard, Pierce-Arrow, Locomobile, etc. In such cases the owner usually has his own garage and will require the installation of a rectifier or motor generator set with which his batteries may be charged. When such a case arises would it not be a wise move on the part of the central station to give its part of the installation immediate attention, instead of dallying along for several weeks, during which time the new electric car owner becomes disgusted with the entire proposition? The rate charged for current in private garages should be gotten down as low as is consistent with local conditions. When the lady owner of an electric car tells her friend whom she may meet at an afternoon tea that her electric car current bill last month, who drove her car in the vicinity of 600 miles, was less than $10, you may be sure the friend resolves to make a strong point of this fact when she next discusses the matter with the master of the house.

Some of you present may consider it impossible to so cheaply operate an electric car. Gentlemen, I hold in my hand power bills for operating my two electric cars in Detroit which during the past two months cost respectively $5 and $7. The Detroit Edison Company is thriving under these conditions. Its stock is way above par and indications are that it is going much higher.

That there is a just reason for the intensified efforts of the central station manager to promote the use of electric vehicles in his territory, is most ably and conservatively outlined by Mr. H. W. Hillman in his paper read before the Electric Vehicle Association of America on the evening of Jan. 21. Mr. Hillman closed his paper with a statement based on Mr. Edison's prophecy that "with the proper efforts extended by the central stations throughout the country, an increased income to those companies will be realized, amounting to $480,000,000 within the next 15 years."

Aside from the promotion work being done in Boston and New York, much credit is due to other central stations in New England, these including the Northampton Electric Light & Power Company, Northampton, Mass.; Greenfield Electric Light & Power Company, Greenfield, Mass.; Middletown Gas & Electric Company, Middletown, Conn.; United Electric Company, Bridgeport, Conn.; United Illuminating Company and Union Gas & Light Company and the New Haven Gas & Electric Company, New Haven, Conn.; Norwich Gas & Electric Company, Norwich, Conn.; Edison Electric Illuminating Company, Brockton, Mass.; New Bedford Gas & Edison Light Company, New Bedford, Mass.; Lowell Electric Light Company, Lowell, Mass.; Holyoke Gas & Electric Company, Holyoke, Mass.; United Gas & Electric Company Springfield, Mass.; Worcester Electric Light & Power Company, Worcester, Mass., and others who have purchased electric cars for their own use and in other ways promoted the industry.

At Hartford, Conn., the Hartford Electric Light Company maintains a battery department where owners of electric vehicles may rent batteries at a fixed cost per mile or per year, as may be required. This policy relieves the vehicle owner from investing his money in battery equipment, also of the fear so many purchasers seem to have that a storage battery is difficult and expensive to maintain. This policy has resulted in largely increasing the electric vehicles in Hartford. It would be well worth your time to appoint a representative to visit the Hartford station to investigate this particular action.

In every city large enough to support a central power station there are great opportunities for electrically propelled vehicles. If the fabric mills in this territory are not all put out of business because of recent tariff legislation they will still have to transport their raw and finished material to and from depots or boats, as well as cart them about their plant. This work is now being largely done in the former case by horses and in the latter by hand trucks, pushed by laborers. Every effort should be extended by the central station in these localities to see to it that these horses be replaced by electric vehicles, and that the hand trucks be discarded for the electric industrial trucks, which are being successfully operated today by many railroads and industrial enterprises.

Within the very near future, if every central power station throughout the country will put its shoulder to the wheel and push the electric vehicle industry with a force relative to its merit, the problem of "What shall we do with our off-peak production?" will be a matter of minor consideration to the central power station.

Following this paper was discussion, and then came the paper on "Proper Selling of Electric Cars" by Louis E. Burr of the Woods Motor Vehicle Company, Chicago, Ill., which was read in the absence of Mr. Burr. This paper was in part:

Proper Selling of Electric Cars.

In offering this paper I desire to say that the ideas presented are by no means claimed as original, and my only excuse in coming before you is the conviction that the subjects mentioned are important ones and it is possible that some good may come from the fact that they are brought to the immediate attention of the convention, which may result in fruitful discussion of them.

Central stations—I am free to say that the subject of the central station is rather a hazy one to me, insofar as offering new ideas regarding it. I know very little about the central station, what it wants to do—and its ability to perform—but I do know, of course, that the central station of today is very different from the central station of even a very short time ago.

About five years ago a Woods Electric was driven overland from Chicago to Lincoln, Neb., and about that same time another trip was made from Philadelphia to Pittsburg over the mountains, both trips being considered quite remarkable at that time on account of the fact that the journeys were by electric car. During these journeys our men, who made the runs, were hampered a great deal by lack of proper charging facilities and were obliged to resort to all kinds of methods and devices known to the electrician to charge the battery, even when they arrived at a town where there was a central station. The central station manager was invariably courteous and ready to oblige, but as a rule possessed absolutely no knowledge of the method of charging an electric car.

I believe that should these same routes be followed at the present time the conditions—so far as central stations are concerned—would certainly be very much improved, and it is my belief that the campaign of education carried on through the Electric Vehicle Association, and in other ways, has awakened the central station to the great possibility of the electric vehicle business as a source of profit to the central station. I would think that a central station that can afford to would have an electric vehicle of some kind—either a commercial or pleasure vehicle—in its possession for its daily use, to create a desire in the minds of the people to own an electric vehicle, perhaps as much on account of the ease with which it can be cared for and charged as for any other reason. It is a self-evident fact that the price at which current is furnished is a potent argument in favor of the machine and the price should be made as low as possible, consistent with the conditions. In other words—the closer the central station and the electric vehicle dealer can get together the more business there will be for both and the greater the mutual advantage.

Service—The question of service at the present time is, to my mind, a very important one. It is a very much abused word and may be compared with the so-called "guarantee" offered by a great many dealers. A guarantee means exactly what the guarantor intends it to mean—nothing more or less. Service may be catalogued under the same head. The average buy-

(Continued on Page 463.)

THE PHILADELPHIA THIN PLATE BATTERY.

By James M. Skinner.

THE following is the second and concluding installment of the paper read by James M. Skinner, engineer of the Philadelphia Storage Battery Company, before the New York section of the Electric Vehicle Association of America. The first part was published in the May issue of the Motor Truck. The review deals with the characteristics and qualities of the Philadelphia storage batteries in particular and the thin plate battery in general, with particular reference to mileage capacity and longevity:

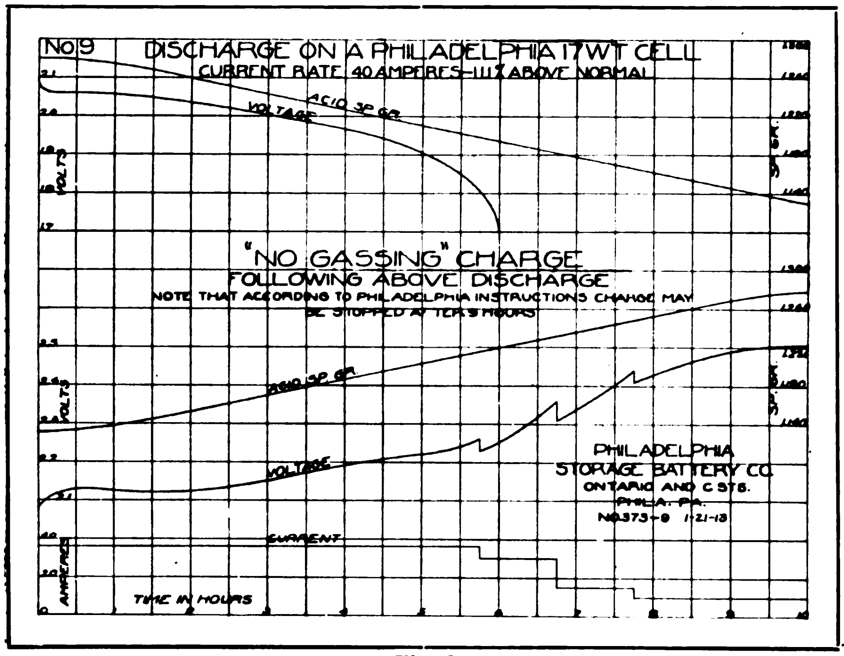


Fig. 9.

Efficiency.

The service watt-hour efficiency of Philadelphia thin plate batteries is upward of 70 per cent. This is based on 44 cells and a charging voltage of 115. Note that the efficiency has been figured from the 115 volts of the charging circuit, and not from the considerably lower average charge voltage across the terminals of the battery, because the current is metered and paid for at 115 volts regardless of the battery voltage.

Considering the proposition of charging from a theoretical standpoint, the more free surface the active material exposes, the easier it will be to charge without gassing. If gassing is not permitted, the ampere-hour efficiency rises close to 100 per cent. With some batteries gassing is a fundamental and necessary thing; the efficiency of these batteries is therefore low. With thin plate batteries gassing is not fundamental nor necessary. Hard gassing is criminal. It is a waste of current and of money, and since it washes the active material off the plates, it is a very good means of shortening the life. It is perfectly possible to charge a thin plate battery with almost no gassing. The Philadelphia Storage Battery Company has for some time advocated a "no-gassing" charging procedure. Where it has been adopted it has resulted in an extraordinary increase in battery life. It is very simple. Each daily charge is started at the normal discharge rate, and the current maintained at this point until gassing commences. The rate is then reduced in several steps, keeping below the gassing point at all times, until the low finishing rate is reached. At the finishing rate gassing is so slight that it can do no harm, and the charge is continued until the total battery voltage has risen to within about two volts and the specific gravity to within five or 10 points of the maximum obtained on the last previous overcharge. Once a week, or in light service, once every two weeks, the battery is given an overcharge at the finishing rate until the voltage and specific gravity have stopped rising for four hours. To illustrate how very simple these "no-gassing" charges are, Fig. 9 has been prepared. This shows a discharge on a 17 WC cell at 40 amperes, 111 per cent. of the normal six-hour discharge rate. Six hours were obtained at this high rate, so the cell was rather fully discharged. The lower curves show the following charge. You will note that only three reductions of current were necessary, all in the second half of the charge. This is not an exceptional case. The charging time can be materially shortened if desired. I have ventured to introduce this instruction book matter because it is vital. When means are at hand to increase the life of batteries from 20 per cent. to perhaps even 100 per cent. in the worst cases, they are of sufficient importance to merit the attention and deserve the support of every person in any way interested in electric vehicles.

It is easier to eliminate gassing on thin plate than on thick plate batteries. Gassing in lead batteries is due to the inability of the charging current to find lead sulphate. Whenever there is any current in excess of the amount which can find lead sulphate on which to expend its energy, that current dissipates itself in breaking up the water of the electrolyte into gas. If the sulphate is situated in the depths of a thick plate or if it is covered over, it is difficult to reach, and gassing and low efficiency are harder to prevent. In thin plate batteries, with their readily accessible active material, gassing is easier to prevent, and the efficiency is therefore high.

Life.

The increased capacity of Philadelphia thin plate batteries has not been obtained at the expense of life. Far from decreasing as the plates were thinned down, the life of Philadelphia batteries has actually increased. Of course, there are a number of incidental reasons why this should be so in service. Batteries today are being more intelligently handled, better charging methods are coming into vogue, cars are better designed and draw less current. But even in the laboratory, under exactly the same conditions of handling, Philadelphia thin plates give longer life than thick plates. The diamond grid is a big factor in long life, and certainly the diamond grid is even more necessary for thin plates than for thick. But all Philadelphia plates are built up on diamond grids, and the increased life of Philadelphia thin plates over Philadelphia thick plates cannot be ascribed to this feature alone, however advantageous it may be.

Disregarding this advantage, common to both thick and thin plates of Philadelphia manufacture, it seems as if there must be certain other qualities inherent in thin plates that make for longer life. Most of these have been referred to in previous parts of this paper.

First, the active material is better distributed, therefore, the internal strains due to discharge are less. This is true even

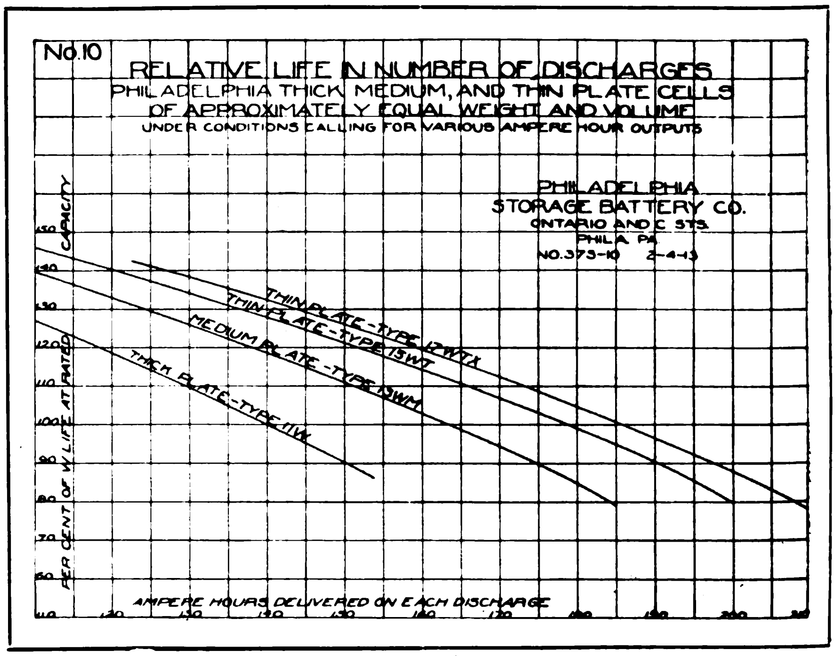

Fig. 10.

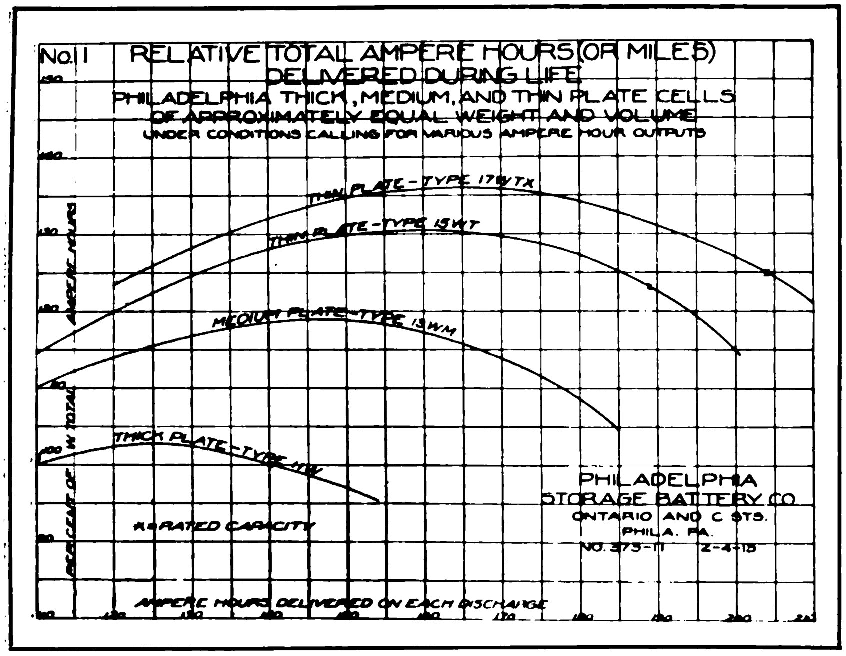

Fig. 11.

of full discharges, and on moderate discharges they are very much less.

Second, due to larger plate surface and the better accessibility of the discharged material, gassing is reduced, and where the "no-gassing" charging method is in use, the wear due to gassing is only a fraction of that on thick plate batteries charged until they "gas freely," as by the old instruction books.

Third, as will be shown later, the growing tendency toward installing larger batteries is having a marked effect in increasing life.

And finally, thin plate batteries maintain high capacity until almost the end of their lives, whereas thick plate batteries have a habit of gradually decreasing in capacity until they give less mileage than the service demands. Furthermore, it is possible to work thin plate batteries to a far lower point, because, even when they have fallen to 70 or 75 per cent. of their rated capacity, they will still give more than full thick plate mileage. It is characteristic of worn out thin plate batteries that they look worse than worn out thick plate batteries, which is to their credit. They have worked efficiently up to their last ounce.

For any given ampere-hour output a discharge, the number of discharges obtained during life increases progressively from W to WTX. This is shown in Fig. 10. Here have been plotted the relative number of discharges obtained from Philadelphia thick, medium and thin plate cells, of approximately equal weight and assembled in the same sized jars, under conditions calling for various ampere-hour outputs a discharge. The 11 W life under rated capacity discharges has been taken as 100 per cent. If discharged only to 11 W capacity, 140 ampere-hours, the 13 WM will give 118.5 per cent. of the W life in discharges, the 15 WT will give 128 per cent, the 17 WTX, 132 per cent. The total miles obtained during life increases in the same proportion. The 11 W will not give 168 ampere-hours, the 13 WM capacity, but if the 13 WM, the 15 WT, and the 17 WTX are run to 168 ampere-hours on each discharge, the WM will give 96 per cent. of the W life in discharges, the WT, 108 per cent., the WTX 114 per cent. If all cells are run to full rated capacity on each discharge the W will give 100 per cent. life, the WM 96 per cent., the WT 91.5 per cent., and the WTX 84.5 per cent., but the WM has given 20 per cent. more miles a discharge than the W, the WT 35 per cent. more, and the WTX 46 per cent. more. If all cells are run to such capacities that they give W life in discharges, the WM will give 17 per cent. more mileage a day than the W, the WT, 27 per cent. more, the WTX, 33 per cent. more.

By multiplying the number of discharges by the ampere-hour output a discharge, there is obtained the total number of ampere-hours delivered during life. This calculation has been made on the four cells of Fig. 10, and the results have been plotted on Fig. 11. The total ampere-hours delivered by an 11 W cell discharging to 140 ampere-hours a discharge has been taken as 100 per cent. You will note that the number obtained is a variable quantity, depending on the cell considered, and upon the number of ampere-hours taken out a discharge. It increases from W to WTX. At any given ampere-hour output a discharge the 13 WM will give more total ampere-hours than the 11 W, the 15 WT more than the 13 WM, and the 17 WTX more than the 15 WT. Each curve has a hump in it. These humps show the points to which the cells should be discharged in order to obtain maximum life in ampere-hours (or in miles). To obtain the maximum life in ampere-hours from an 11 W cell, it should be discharged only to 126 ampere-hours, 90 per cent. of its rated capacity. This is usually impossible in service, because the thick plate capacity is low, and 90 per cent. of it will not usually cover the mileage requirements. To obtain maximum total miles from a 13 WM, 148 ampere-hours, or 88 per cent., should be taken a discharge. This is sometimes possible, because even then the 13 WM will give nearly 6 per cent. more mileage a day than the 11 W. The 15 WT maximum is at 160 ampere-hours, 85 per cent. of its rated capacity, and the WTX at 164 ampere-hours, 80 per cent. of its rated capacity. It is usually possible to install WT and WTX batteries of sufficient size to obtain this maximum life, because even when discharged only to 85 and 80 per cent. of their rated capacities they give 14 to 17 per cent. more mileage a day than the W battery of equal size and weight.

If discharged to full rated capacity each day the WM will give 114.5 per cent. of the W life in ampere-hours, the WT, 123 per cent., the WTX, 125 per cent., while if discharged only to such an extent that maximum life is obtained, the WM will give 19 per cent. more than the W normal life, the WT, 30.5 per cent. more, and the WTX, 36 per cent. more. The differences between the ampere-hour lives at normal capacity, and the maximum lives, are not so large as to be startling—from 4 per cent. on the WM, 6 per cent. on the WT, and 12 per cent. on the WTX—but they are large enough to be worthy of some consideration. Perhaps the desirability of using batteries of the proper sizes for their work will appeal more strongly if the curves are transferred to a dollars and cents basis. This has been done in Fig. 12. The dips correspond to the humps in Fig. 11, only the thin plate cost is lower and the thin plate curves are here below the thick plate curves. When run at rated capacity the WM cost a mile is 91 per cent. of the W, the WT 90.3 per cent., and the WTX 90.6 per cent. When run at a capacity so as to give maximum total mileage the WM cost a mile is 12 per cent. less than the W, the WT, 14 per cent. less, the WTX, 17 per cent. less, despite the fact that in each case more miles a day, more days of service, and more total miles are obtained.

This matter of maximum life is very important. To make it even more clear, Fig. 13 has been prepared. This shows the relative number of discharges and total ampere-hours obtained from WT cells, when discharged to different percentages of rated capacity. As before, to obtain maximum life in ampere-hours, 85 per cent. of rated capacity should be used on each discharge. If more than 85 per cent. is used, the cell will give fewer discharges and a slightly smaller total ampere-hour output; if less than 85 per cent., more discharges but a smaller number of ampere-hours than the maximum will be obtained.

The proper time to adjust the size of the battery so as to obtain the maximum total output and the lowest cost a mile is before the purchase. It is a much harder proposition to adjust the work to the battery than to initially adjust the bat-

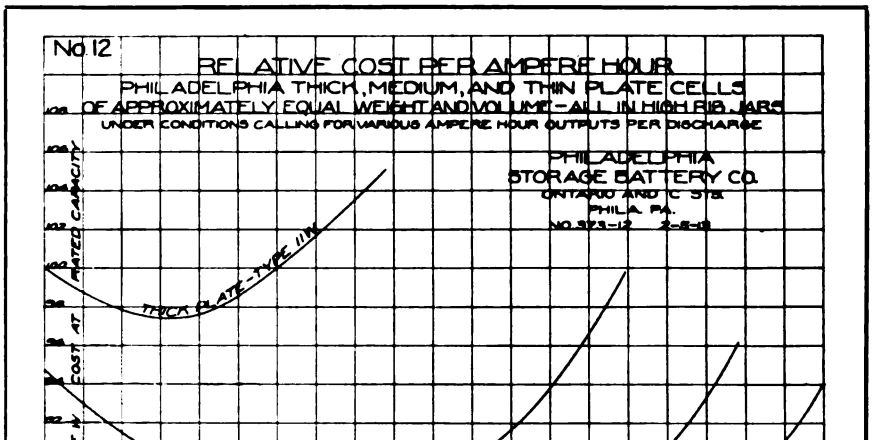

Fig. 12.

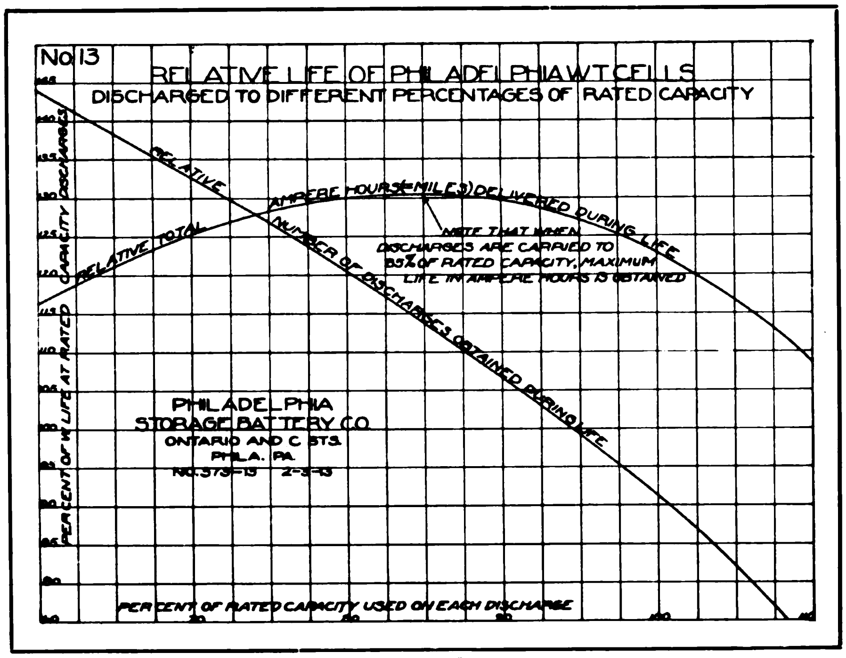

Fig. 13.

tery to the work. If the battery is already in the car and the car must do 50 miles a day, the battery will in most cases have to give the 50 miles, whether it thereby discharges to 60 or 100 per cent. of its rated capacity. But the better way would have been to have first figured out how many ampere-hours the 50 miles required, divided this figure by .85 in the case of WT batteries (.88 for WM or .80 for WTX), and to have determined the size of battery according to the result obtained.

Fig. 14 shows curves plotted from a little more extended calculation along this line. Here it is assumed that 200 ampere-hours are required a discharge, and it is desired to install the size of WT battery which will most cheaply do the work. The horizontal scale in the sketch shows the rated ampere-hour capacities of the cells that might be installed. The vertical scale is divided into per cent. The curve starting at the lower left hand corner shows the relative number of discharges which will be obtained from the various sizes. The figures for this curve are obtained by determining the per cent. of rated capacity to which each size must be discharged in order that it should give 200 ampere-hours, and then determining, from the curve on Fig. 13, the life in discharges obtained when discharging to this percentage of rated capacity. Since 200 ampere-hours are required on each discharge, regardless of the size of cell, this curve also shows the relative total ampere-hour or mileage output obtained from the various sizes. The cost a mile curve is plotted from the results obtained by dividing the catalogue price for each cell by the relative mileage obtained from it during its life. You will note that the 19 WT, which, to give 200 ampere-hours, must be discharged to about 85 per cent. of its rated capacity, shows the lowest cost a mile. The figures for this cell have been taken as 100 per cent.

It is impossible this evening to give more extended figures. Those shown will serve to indicate the general procedure to be followed in economically adjusting a Philadelphia battery to the work it must perform. If further data is desired, we will be only too glad to supply it individually upon application.

It must not be thought that it is forbidden to use the full capacity of Philadelphia thin plate batteries. If exceptional mileage is required it may be advisable and necessary to use all the capacity the battery can give, and the results obtained, even under these conditions, will be good, but the life will be somewhat longer and the cost a little lower if matters can be adjusted so that somewhat less than full capacity is demanded. Our idea in presenting the figures covering this point is not to make it a hard and fast rule that just so much capacity, and no more nor less, must be used, but merely to indicate how the best results may be obtained.

Besides making for longest life, reserve capacity has other advantages. Every car is likely to meet extraordinary conditions which require more ampere-hours than usual. Bad weather, exceptionally long runs, and overloads are of not unusual occurrence. Reserve capacity in the battery is then a very valuable asset. Because of their high capacity, thin plate batteries can generally be installed so as to have sufficient reserve to meet these unusual demands, thereby adding to the day in and day out reliability of the car. It is the thin plate reserve that "gets there" under any conditions.

Service.

The average life of Philadelphia thin plate batteries, in electric truck service, under all sorts of conditions, is about 16 months, and is steadily increasing. Where the methods of handling are good, 20 months is the average, even in hard service, and cases of two years and over are not uncommon. In pleasure cars the life is usually greater. When the "no-gassing" method of charging and the growing tendency to install larger batteries become more general, we have no doubt that even in commercial service a life of 20 months or more will be average.

Just one more point before I close. Philadelphia thin plate batteries are adapted to every kind of electric vehicle service. They will give exceptionally high mileage, but they are not to be used only where high mileage is desired. If the mileage requirements are low, fewer plates may be used, or the battery may be charged only every other day, or perhaps twice a week. This is good practise in light service. If the service conditions are unusually severe, a Philadelphia thin plate battery is required all the more. Hills and bad roads have no terrors for it. High discharge rates will not hurt it. Current can be withdrawn at as high a rate as the service demands. I want to emphasize this point of general adaptability. There is no kind of electric vehicle service to which Philadelphia thin plate batteries are not adapted.

The Independent Torpedo Company, Findlay, O., which deals in nitro-glycerine and other high explosives, uses a Reo delivery wagon in connection with its distribution, and has 12 Reo two-passenger roadsters that were bought for delivering torpedoes and material in the states of Indiana, Ohio, Illinois, Kansas and Oklahoma.

Two three-ton Kelly trucks, made by the Kelly-Springfield Motor Truck Company, Springfield, O., are being used by the Merchants' Express of Bridgeport, Conn. These vehicles run on regular schedule between Bridgeport and nearby cities every day. Each averages more than 70 miles each day.

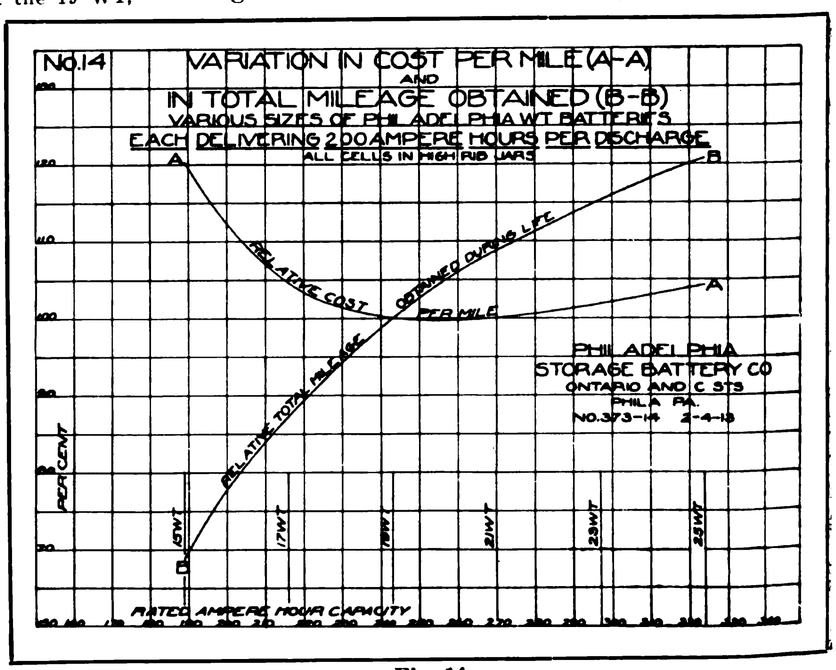

Fig. 14.

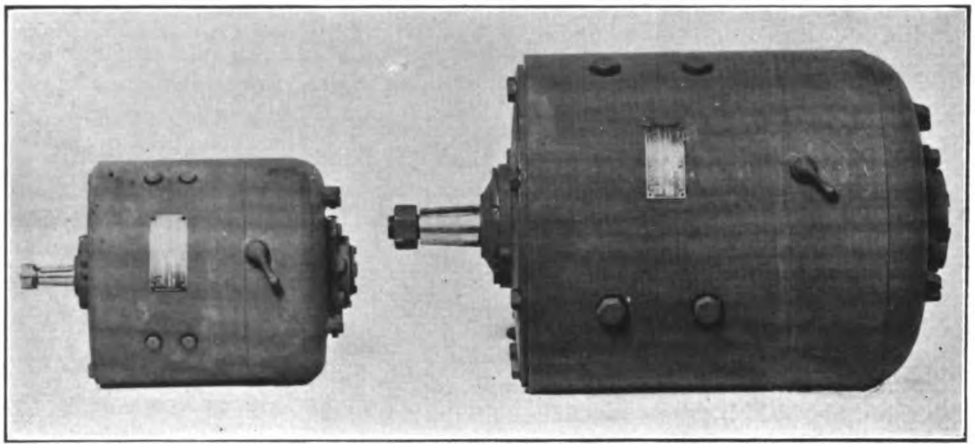
ELECTRIC VEHICLE PRACTISE.

The Construction of the Universal Motor of the General Electric Company, a Standard Type of Equipment, and the Processes of Building to Insure Endurance and Efficiency---Extreme Care in Making Commutators and Armatures.

William W. Scott.

WITH rare exceptions the motors used for electric vehicles are made by manufacturers who specialize in electrical equipment, and generally these have been designed with careful knowledge of the conditions of service in which they will be used. It is hardly necessary to point out that some of these concerns produce thousands of motors annually, and have large experimental and engineering departments, with the best of facilities and almost unlimited resources for development. Naturally the designs are made with exact knowledge of requirements, and with the experience resultant from the production of different types and the observation of many thousand machines it is entirely reasonable to assume that the motors are in every way efficient, economical and enduring. Everything depends upon design. The engineering departments are required to produce numerous sizes and greatly differing proportions to accomplish specified works, and with the precise calculations possible with electric units of measurement it is not too broad a statement to say that practically any desired result can be obtained. These manufacturers have admirable shop facilities and equipment, and the workers are experienced and skilled, so that motors supplied to a number of vehicle builders ought not to vary with reference to capacity and service. By this is meant that a standard make of motor ought to be equally as serviceable in any vehicle in which it is found.



Comparative Sizes of the General Electric Universal Automobile Motors, the Smaller Known as GE-1028, Weighing 150 Pounds, and the Larger, Known as GE-1027, Weighing 660 Pounds.

The subject of motor design is extremely important with the manufacturer of such machines, but the purchaser of a vehicle need give himself no concern as to quality. He has bought what has been developed and built with extreme care, and is sent out as factory perfect. It is not necessary for the man who is considering a purchase to take up motor design. This has been gone into by the vehicle builder and the motor manufacturer, and it is reasonable to assume that the latter has placed at the disposal of the former the knowledge and advice of his engineers. The purchaser of an electric machine need have no doubt of the work that will be done by the motor, for it will be equal to every demand made upon it, and it will endure many years with reasonable care and attention.

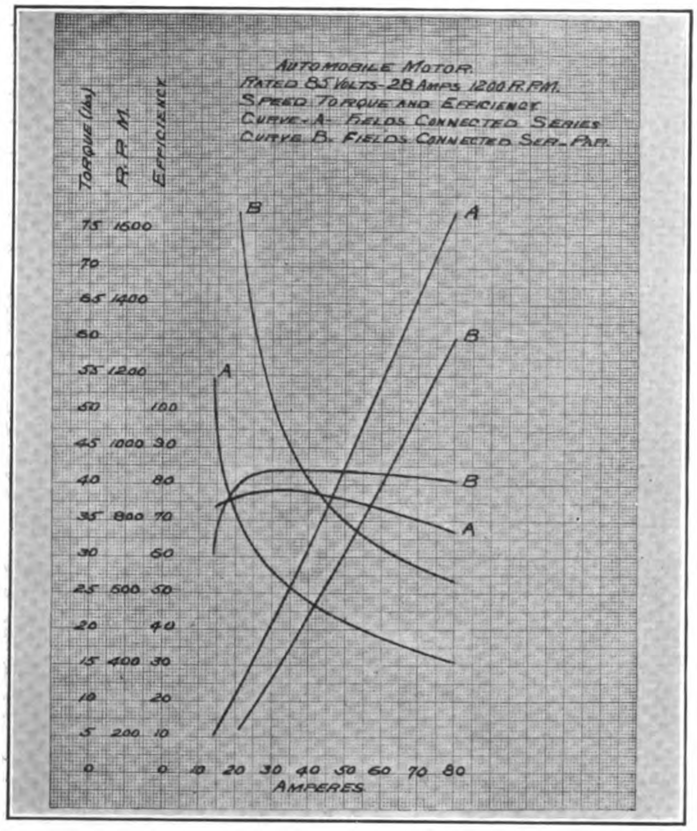
Attention has been directed to the fact that the electric motor has been a dependable machine from every aspect, and the ideal of the engineer has been to produce what will have efficiency and economy, long endurance, and be as cheap as is consistent with a standard of manufacturing. The history of each concern producing a well known motor demonstrates that there has been improvement in designing, in materials, in workmanship and manufacturing methods, but the principles apply to each quite as well as to any one. Some of the manufacturers have processes of treatment, and in some instances proportions, which are maintained to insure efficient and economical results, but these, while regarded as valuable to those possessing them, are details rather than essentials of construction.

There are limitations to the work that can be done with a motor of given proportions. The speed affords power and vehicle motors have maximums ranging from 900 to 1500 revolutions a minute. The power is dependent upon the voltage, and this may be 40 with a very small and very light carriage, or from 60 to 85 with the heavy truck. Taking the series wound motor, the greater the load the less the speed, and the less the load the greater the speed, there being that characteristic of practically automatic control through the load carried. With the old constructions when plain bearings were used the only possibilities for wear were the armature shafts and the bearings, but with the present design, with annular ball bearings, only the bearings can wear, and with sufficient lubrication the only probable bearing defect may be a broken ball or a worn ball race. This probability is exceedingly remote, however.

The only rotating part of a motor is the armature, and mounted on ball bearings it is intended that it

shall be balanced. To its movement there are but three influences for retardation, the friction, the air resistance upon the surface as it revolves, and the load. The load may be carried direct in line with the armature shaft or it may be moved through reduction gearing. The only portion of the armature that may wear is the commutator, which, however, ought theoretically to endure for an indeterminate period. From the viewpoint of the electrical engineer the well designed and constructed commutator should not wear, and under normal conditions a set of brushes should give service for several years.

Every vehicle motor installed today is a housed type, being enclosed in a water and dust tight case to give it the greatest possible protection, and to insure it so far as possible against the influences that might



Speed, Torque and Efficiency Curve of the General Electric Universal Automobile Motor, Rated at 85 Volts, 28 Amperes and 1200 Revolutions a Minute.

cause wear. These housings are of pressed or cast steel and differ somewhat in design. An example of standard construction is the type of automobile vehicle motor made by the General Electric Company which is regular equipment with a number of the best known makes of pleasure cars and wagons and trucks.

It will be noted by reference to an accompanying illustration that the cases of these motors are identical, differing only in proportions. These are known as the universal automobile motor and are produced in eight sizes, the housing being referred to in shop practise as the frame. These frames are steel castings, the bearing head commutator end being integral. Referring to the illustration it will be seen that this end has two lugs which form the hinges on which the aluminum cover plate swings. The frame has four internal lugs at the open end, which take the bolts that retain the end plate, and at the side of the frame just inside the hinged cover plate are two lugs that carry the brush rigging. The first process in working the frame is to machine it inside and out, so that it is practically uniform in thickness and is smooth and finished in appearance. The opening for the hinged cover plate is fitted very accurately by machining, and the cast aluminum cover plate is machined to exactly fit the opening. The end plate is cast iron, ribbed to have lightness and strength, and this is similarly finished by machining.

While the frame is in the hands of the machine tool men it is drilled for the bolt and screw holes. These are seldom varied, save for those for the supporting brackets. In all the shop work fixtures are used, so that each frame is identical, and with any number all the parts ought to be interchangeable. Following the frame through the shop, the cover plate is fitted, and the frame is then ready for the installation of the pole pieces. The universal automobile motor is a four-pole type, and reference to an illustration of the motor will show that the poles are secured to the case by two bolts each. These bolts have countersunk heads in the pole pieces. The pole pieces are oblong in shape and are curved at the top and bottom to conform to the contour of the frame, there being at either side of the top a flange or horn that serves to retain the winding, and also increases the surface area of the pole. The poles are built of a number of sections of soft iron .0625 inch thickness, and secured with two bolts running longitudinally. The poles are not given treatment, the laminations being in contact.

The pole windings are formed to fit closely around the pole pieces, and when the poles are bolted to the frame they are securely retained between the flanges or horns of the poles and the shell. The proportions of these is a matter of design.

The building of the armature is a process that calls for both machine and wire working. The design of the armature is with reference to the work to be done, just as all motors are built for a specific purpose, having different forms of core and windings, and for a definite maximum speed. As has been stated, the number of windings and the number of commutator segments are also matters of design, and the purpose of the engineer is to make the commutator as small as is practicable and the windings as many as is consistent taking into consideration the proportions of the commutator.

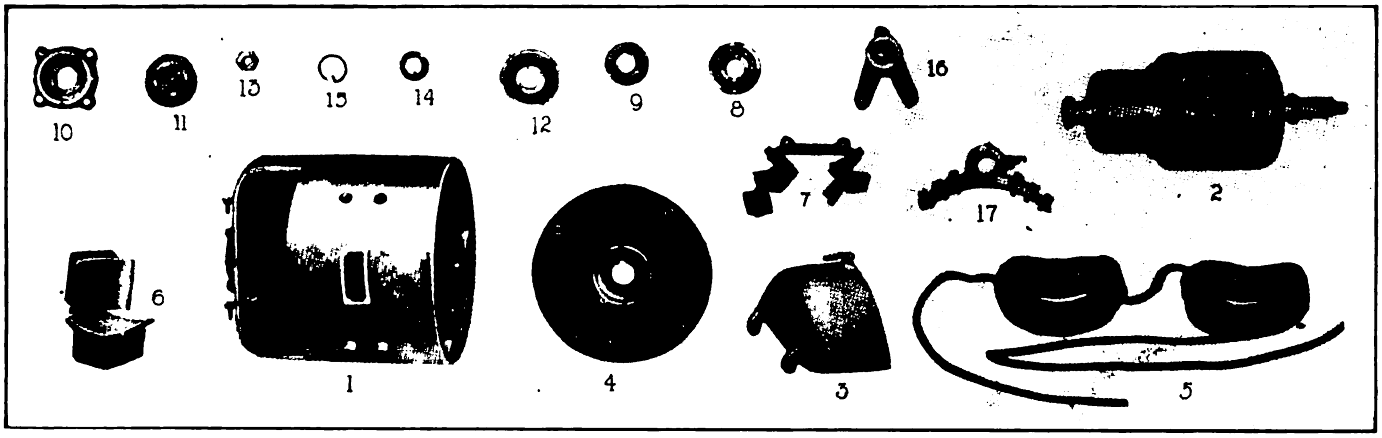
The proportions of the armature used in the universal automobile motor are shown in the accompanying illustrations. The armature shaft is made of a high grade steel, heat treated and very carefully machined, which has a keyway in it. As an illustration of the care in construction it should be stated that each individual bearing is fitted to the shaft, this insuring absolute fit and certainty of operation. On this shaft is fitted the armature core. The armature core is built on what is known as a "quill," this being a

steel sleeve with a collar at the commutator end. The core is composed of a large number of sheets of soft iron approximately .01 inch thickness. These sheets are japanned on either side, this japan serving as insulation. The sheets have cut into the peripheries a number of rectangular channels which might be likened to teeth. These are about twice as deep as they are wide, and as a sheet is seen the bottoms of the channels are closer together than are the tops or openings.

As these sheets are cut at the centre to the exact size of the "quill" when the core is being assembled, the required number is placed on the quill, there being a collar or plate that fits against the collar of the sleeve. The core is placed in a hydraulic press and the sheets are forced together under heavy pressure until they practically form a solid mass. Then an end plate or collar is forced on the sleeve and secured with a lock washer. The core then has a series of rectangular channels extending around its periphery. It may be well to interpolate here that the laminated core is intended to have the greatest permeability and a very

The wire is formed for the winding by bending it about a core, and when shaped it may be said to have two coils at one end and both sides, with the ends of the wire projecting beyond the end that has but one coil. Where the wire is in two coils there is additional insulation about the winding. The ends of the wires are tinned to insure full contact when soldered.

There are two windings in each of the channels of the armature core, the first of which is laid in and the free ends of the wire are soldered into the slots in the armature segments. The windings are so shaped that the sides of each are fitted into two of the core channels, and so the windings are placed in exact relation around the circumference of the armature. After the first winding is laid the ends are soldered to the commutator segments, and insulation is placed above the exposed ends of the wires at the junctures with the segments. Then the second winding is installed. This is done as was the first winding, and then the armature is wound in several places with strong cord to retain the windings. Thus each channel or groove of the armature core is filled with wiring, there being really



The Elements of an Electric Vehicle Motor: 1, Frame or Shell; 2, Armature; 3, Door or Cover; 4, End Bearing Plate; 5, Field Pieces; 6, Field Coils; 7, Brush Holder Yoke, Brush Holder and Brushes; 8, Pinion End Bearing; 9, Commutator End Bearing; 10, Commutator End Bearing Retainer; 11, Motor End Cap; 12, Pinion End Bearing Retainer; 13, Armature Shaft Nut; 14, Motor Bearing Lock Nut; 15, Spring Wire Lock Nut; 16, Radius Rod Socket; 17, Motor Support Bracket.

low resistance, and the greater the number of channels for windings the less is the influence of the eddy currents.

The commutator is composed of a series of segments of wedge shaped copper bar. One end of each segment has a lug or arm at right angles to the section, and the end of this arm and segment is slotted. The segments are mounted in a core of insulating material and between each segment is a sheet of mica. In the making of the commutators great care is taken to have the segments in exact relation, so far as space between them is concerned, and the insulation is very carefully prepared. The commutator is built separately and is assembled with the core when the armature is ready for the winding.

The winding of the armature is really an installation of windings that have been made ready. The windings are of square or rectangular copper wire, there being a stated number in each group. Each group is covered with a heavy cotton tape wound about it, and each of these makes a single winding.

four layers, two of each loop. The ends of the second series of loops are soldered to the commutator segments, and the solder is trimmed and the commutator is made smooth and clean. The core is then wound with wire under considerable tension in several places, and the wire is soldered and the coils are sweated together with solder. This retains the windings firmly in the core.

The core is dipped into an insulating compound that penetrates the cotton covering of the wires and permeates it thoroughly, and after the dipping the core is allowed to drain and dry for six hours. Then it is placed in an oven and baked for 20 hours. This solidifies the insulating compound that is expected to fill every void in the cotton, and makes the windings in the channels practically solid with insulation thoroughly protecting the wires. The purpose is to insulate the windings from the core, and to have perfect circuits through each series of wires from one commutator segment to another.

Extreme care is taken that each armature shall bal-

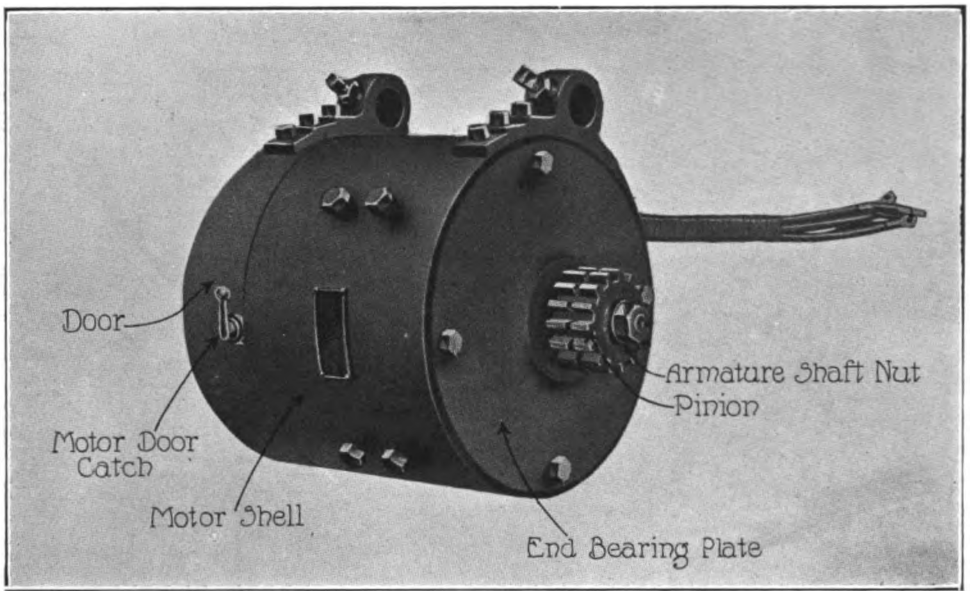
ance. The shaft or spindle is keyed to the quill or sleeve by a keyway that extends through the quill, and it is possible to remove the shaft at any time that this may be necessary. The balancing is accomplished by adding weight to the plate retaining the core laminae, or by drilling it. The next process is to cut out the mica strips between the segments of the commutator to the depth of .0625 inch. This is done by a cutter that revolves on a vertical shaft, and the armature is clamped in a carrier so that the commutator is advanced with the mica insulation between each segment against the cutter. This is practically the final work on the armature aside from polishing the commutator.

It may be well to say a word about the process of insulating the armature by dipping it in a compound and baking it to thoroughly dry the insulation. There are two purposes in the mind of the engineer. The one is to insulate it to secure high electric efficiency, and the other is to protect the wiring against the influences of moisture. The insulating follows this practise throughout the building of all motors, but where a motor is to be used in a country that is excessively humid or wet even greater care is taken, and in some instances the time taken to insulate the armature by dipping in a compound and baking is 100 hours.

The armature as it is completed is an exceedingly substantial and enduring construction, and it is held from an engineering standpoint that it ought to endure for many years, for there is nothing to wear aside from the commutator, which contacts with fiber graphite brushes, and these are in a sense self-lubricating. There is also a lubricating quality to the copper segments, and theoretically a commutator should wear almost imperceptibly in a number of years' service.

The windings of the pole pieces are subjected to the same method of insulating as are the armature windings, but these are treated by a vacuum process, so that the compound is forced into every void of the cotton covering of the wire, and this insures against every possibility of leakage. When the insulation has been baked the pole windings are practically solid, the wire being held by the compound that has permeated the cotton fabric between the coils.

The pole pieces and the windings are bolted to the motor frame, and in the assembling the armature shaft or spindle is mounted on two annular ball bearings, that at the commutator end being mounted in what is known as a retainer, which is covered by a cap. The bearing at the pinion end of the shaft is supported by the motor end bearing plate, being carried by a collar that is known as a retainer. This retainer is bolted to the end plate. The bearings are firmly fixed on the shafts by retaining nuts, and the bearing caps protect the bearings and serve to retain the lubricant. When the motors are assembled the bearings are packed with refined vaseline, which lubrication ought to serve for a period of approximately six months.



The General Electric Company's Universal Automobile Motor, Fitted with Supporting Brackets and with Sprocket for Morse Silent Chain, as Installed by the General Vehicle Company.

The brush rigging consists of a brush holder yoke, which is bolted to two lugs inside the motor frame, and this supports the brush holders. The brushes are rectangular, with flat ends that contact uniformly with the surface of the commutator, there being a spring pressure of 3.5 pounds a square inch of brush contact surface. The lugs are drilled so that the brush holder yoke may be set about .125 inch from the surface of the commutator, and there are two positions possible, so the motor may be operated either clockwise or counter-clockwise by giving the brushes the shift to the other possible position. As the motor frame is machined it is drilled for the necessary support brackets and for the installation of a radius rod, for it is important that the relation of the motor with reference to the method of power transmission be maintained. The supporting and radius rod brackets are not included in the motor equipment.

In the construction throughout the greatest care is taken to insure perfect work and to have substantial and enduring insulation. Every test that is practical is made during the progress of the work, and after the motor is assembled it is tested by driving it for 45 minutes as a generator and driving it a similar period as a motor. In these tests very careful observation is made, and it is maintained from long experience that if there is any fault or defect in a machine it will be developed. If any condition is noted that needs attention it is remedied and the motor is not approved unless it is up to the standard of the shop.

It is not necessary to specify what conditions

might be developed by the tests, for these are of no importance to the purchaser, either as a manufacturer or user of vehicles, but it may be said that where defects eventuate in motors in service these are the result from conditions that were not manifested in the very exacting testing work.

The facilities for work turned out by the manufacturers of standard motors are of the highest class. The machine tools are the best that can be purchased and the men who handle them work very close, multiplying gauges being necessary where the limit may be .001 inch. The windings are made with great exactness, being formed on cores and the cotton being reinforced with sheet mica or varnished fabric wherever it is believed necessary. All the leads from the coils have carefully soldered terminal connections, and the cable is large and heavily insulated. In the windings rectangular wire is used with the view of getting all the copper into an armature and coils that is possible.

(To Be Continued.)

CENTRAL STATION PROMOTION.

Salesroom Displays of Vehicles and Reduction of Current Rates Suggested.

The subject of central station co-operation and promotion was discussed by W. C. Anderson, president of the Anderson Electric Car Company, Detroit, Mich., at a banquet of the Chicago section of the Electric Vehicle Association of America, and he urged that the Commonwealth Edison Company of Chicago co-operate with the electric vehicle manufacturers and salesmen to bring about the more general use of machines. Mr. Anderson contrasted the endeavors to stimulate the demand for electric household appliances and those directed toward the encouragement of the use of cars and wagons. He suggested that a section of the splendid new showrooms of the company be given over to the display of an electric housed in a structure suitable for a private garage.

Mr. Anderson made a plea for more charging stations and a lower current rate in Chicago, which he pointed out would give the character of service desired and would impel the use of machines. He maintained that while the utilization of the electric vehicle was increasing at a surprising rate, there was no reason to doubt that the industry would benefit in ratio to the opportunities and reasons the public had for using them. Chicago should be the greatest electric vehicle city in the world, Mr. Anderson stated, because of its physical conditions, and assuming that there were 5000 pleasure cars and 5000 service wagons in use there, instead of 3000 pleasure cars and 600 wagons, the revenue from power alone for the Commonwealth Edison Company would be approximately $1,685,000 a year. This estimate was based on an income of $8 a month from pleasure machines and $20 a month for service wagons. No other department of the business offered such desirable possibilities. Mr. Anderson held that the co-operation suggested would increase the use of electric vehicles in Chicago 100 per cent. in two years.

ROAD MAPS FOR ELECTRICS.

New York Electric Vehicle Association Lists Charging Stations in Large Section.

The New York Electric Vehicle Association has published a handbook, which may be obtained at request made to the secretary of the association at 124 West Forty-second street, New York City, which is extremely valuable, and should be copied by other organizations engaged in promoting the use of electrics, both passenger and freight vehicles. The book gives a list of all the charging stations in New York City and Brooklyn, and then alphabetically lists the stations south to Philadelphia, west to Easton, Penn.; north to Hudson, N. Y., and Pittsfield, Mass., and east to New Haven, Conn., as well as a large number of intermediate points. Accompanying this is a map which shows the location of 65 charging stations outside of New York, and it is entirely practical with this to lay out routes for both pleasure and for delivery or haulage anywhere within the area referred to with a certain knowledge of always having current available. Examination of the map gives one a very comprehensive idea of the possibilities for the use of electric machines within a territory that extends from Atlantic City to the south end of the Taconic range of mountains in northwestern Massachusetts, and from New Haven to the Delaware river, as well as a considerable part of the western half of Long Island.

The list designates the charging capacity of each station, and whether or not garaging conveniences may be obtained, the stations being grouped as those with charging facilities of 50 amperes or more, or less than 50 amperes, and those which have not been definitely reported. In addition the book gives distances in different sections of New York City, and summarizes the attention that should be generally given to lead and nickel-iron batteries, and the specific care that each should receive. The lists, maps and other information were prepared by the automobile bureau of the New York Edison Company.

The agency for Atlantic electric wagons and trucks in Montreal, Canada, has been established with A. Jennings & Co., Wellington and Grey Nun streets, in that city, by the Atlantic Vehicle Company. Electric service wagons have been used in Montreal for about two years and while not at first regarded with favor the very low cost of upkeep and maintenance of the machines in use has directed the attention of business men to their economy and reliability, and there seems to be a promising market in Montreal and vicinity.

The possibilities of the electric vehicle have not been appreciated in many of the European nations, and at the showing of motor cars and wagons at Prague, Austria, not a machine of this type was displayed.

NEW CHASSIS CONSTRUCTION DETAILS.

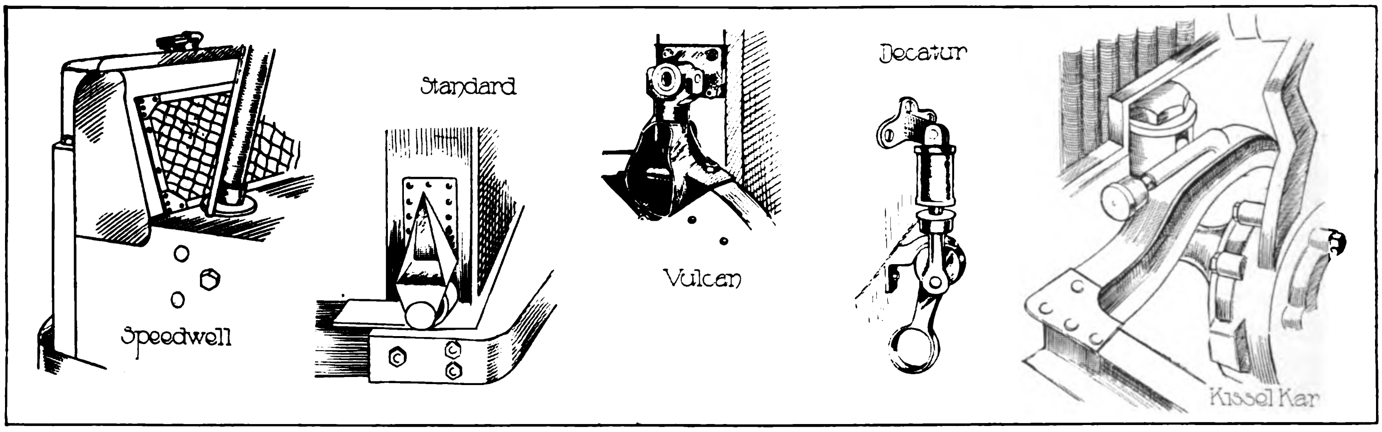
Spring Supported Motor of the Kissel 2500-Pound Wagon---Means for Increasing Strength, Endurance and Efficiency and Eliminating Destructive Influences of Operation.

IN THE improvement of an existing construction the chief purpose of the engineer is to bring about the result desired with the least possible change in the design as a whole, and generally this problem requires much more study and attention than is believed by those who have not actual knowledge. As a manufacturing proposition it is desirable to have work uniform throughout wherever this is practical, and usually this means that the designing has been with a view to production in considerable volume. In shops having large outputs machine tools with jigs or fixtures are always used, and there must be patterns for casting, dies for drop forging, and other special equipment that is costly. Wherever changes are made it is always desirable to utilize as much as is practical of the tools and fixtures, and the question of economizing the expense of changing is often extremely important.

What may appear to be an extremely simple matter when viewed by the casual observer, may be exceedingly complicated when production is considered. A trifling change may represent an expenditure of a considerable amount, and when a number of improvements have been made it will be understood that refinement is only accomplished at material expense and patient observation. For this reason a number of features may be found in a new design that may not be found in any of the productions of the same maker, no matter how carefully the others may have been developed. There are no doubt good reasons for the features of any construction, and occasionally a wide variance is made from generally accepted practise.

An illustration of this may be seen in the 2500-pound KisselKar delivery wagon, in the manner in which the power plant is carried. The purpose of practically every designer has been to protect the motor against the effects of chassis distortion, and this has brought about differing installation. The engine may be carried by the main chassis frame or a sub-frame, and it may be supported by front and rear cross arms or flanges at the front and rear of the case. Ordinarily the chassis frame is the support, but the sub-frame, while it is less susceptible to the stresses of a distorted chassis, is held to add weight and to increase the number of parts. In several instances the motor is carried by a yoke and trunnion at the forward end with the supporting arms at the rear, and in one design the motor is mounted with a ball and socket support at the centre of the front cross frame member and mounted at the rear on lugs carried on guides on which it has a longitudinal movement. In another design there is a sub-frame that is mounted as is the motor just referred to. The endeavor to minimize the vibratory effect on the power plant has resulted in two designers placing the motors on springs. Both of these machines are five tons capacity and naturally subjected to excessive road shocks and the engines have been protected so far as this may be done by the use of leaf springs.

In the design of the 2500-pound KisselKar wagon the engine is carried in a sub-frame, the forward member of which is arched. On this is bolted a bracket with a lug in which is drilled an eye. On the forward cross frame member is a bracket with a heavy cylinder slotted vertically. In the centre of this cylinder is a large bolt. The drilled lug of the sub-frame bracket is placed in this cylinder between helical springs, and the bolt serves as a guide and retains the lug, and the weight of the sub-frame and power plant is carried on the helical spring. Any shock is absorbed, the twist or "weave" of the chassis is compensated by the spring, and the frame is practically free from the influences of operation. The frame is similarly supported at either side near the ends of the side members. The vibrations from the engine are absorbed materially, and it is claimed for this construction that there is no possibility of the motor being affected by the character of the roads.



The Grating Dash of the Speedwell Trucks, C-Spring Radiator Mount of the Standard Machine, Ball and Socket Support of the Vulcan Radiator, the Decatur Seat and Pan Latch, and the Spring Suspension of the Kissel Motor.

The Speedwell trucks are built with the motor un-

der the floorboards and the radiator is supported above the chassis front frame cross member. Back of it is the body frame, and this is carried up to the top of the radiator case. Were the front floorboards carried up on this frame it would obstruct the flow of air through practically half the area of the radiator, and would lessen the radiation materially. To prevent this and to insure the full efficiency of the radiator with the body design the space back of the radiator is covered with a grating, which may be removed when desired. This affords the best of air circulation and sufficient protection.

The radiator of the Standard truck is protected against vibratory stresses and chassis distortion strains by a bracket riveted to the case that has a trunnion that is fitted to the eye of a C shaped spring mounted on the chassis frame. The spring has sufficient resiliency to absorb all shocks, and the mounting can be removed very quickly should there be occasion to remove the radiator. While not intended to endure direct pressure upon the radiator the spring would no doubt compensate a considerable shock upon the casing.

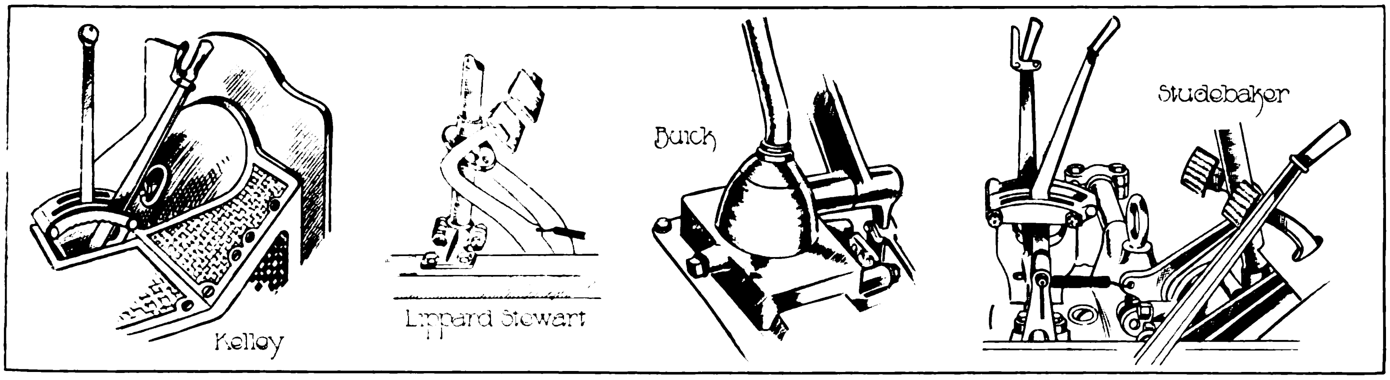
The radiator of the Vulcan trucks is protected against chassis strains by ball and socket supports at either side, the cooler being dropped between the side frame members. This location safeguards it against probable damage from use, and gives a balance that does not bring stresses upon the inlet or outlet manifold connections. The brackets on the chassis frame are large and in these are the sockets in which the globes on the radiator case are carried.

The Decatur wagons are built with a view of having every part very accessible, and the body is constructed so that the seat may be lifted to give access to the mechanism. To secure the seat so that it may not work loose and rattle, and to eliminate any possibility of the seat being thrown by the fastening loosening, a latch is used that has a spring that insures a certain tension after it has been closed. By lifting a lever the latch is opened and the seat may be thrown sidewise so as to expose the engine and transmission.

In the 2000-pound Kelly wagon the radiator is mounted above the rear of the motor, and the footboards are extended forward almost to the engine. It is necessary to have the footboards sharply inclined to the dash to give the needed leg room, and these are cut away directly above the motor. This space is filled by a curved aluminum plate that protects the fan and, being directly ahead of the quadrant of the gearset and emergency brake lever, it is not in any way an inconvenience. The plate is also used in the three-ton Kelly trucks, but it is not as sharply curved. The plates give an unusual appearance to the footboards, but it is not unsightly or objectionable.

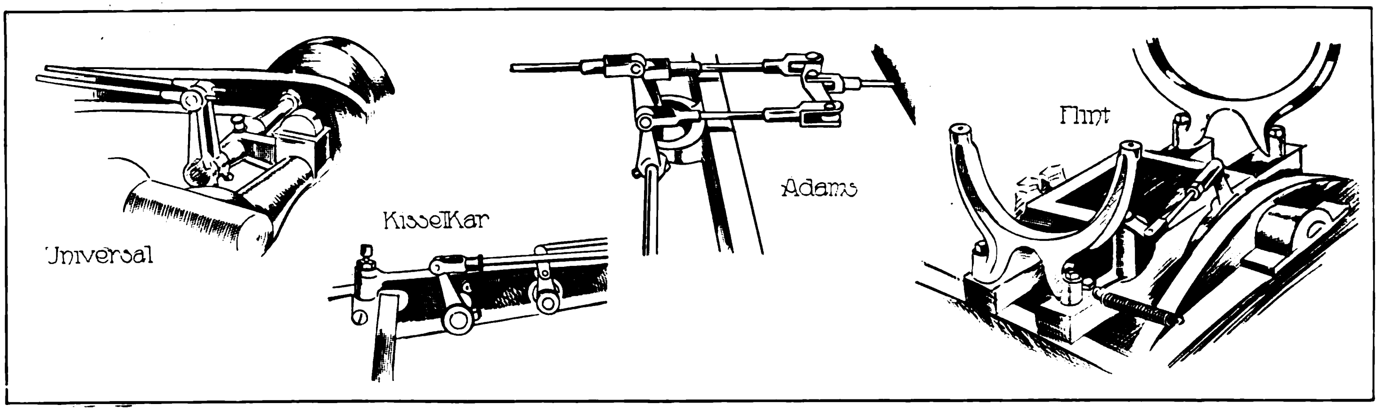
One of the objections to a steering column that is not braced by floorboards is that it will possibly vibrate considerably when a machine is being driven over paving or rough roads, and the effect upon the arms and hands of the driver is benumbing and, in long drivings, even painful. In the Lippard-Stewart delivery wagon construction the steering post is installed close to the left chassis frame side member, and a brace from the frame clamps the post, amply stiffening it. The clamp may be removed in a moment when this is necessary.

In the Buick 1000 and 1500-pound delivery wagons the transmission gearset case is not assembled with the power plant, but it is installed in the rear end of the sub-frame in which the motor is carried. The gear changing lever is mounted on top of the gearset case cover and in a globe socket, so that the changes are made by rocking the lever and moving it as though it were carried in a quadrant of the ordinary type. The emergency brake lever is supported by a shaft at the right. The space between the two levers is more than ordinary, this being necessary for the movement of the gear lever. The appearance of the installation is unusual. The illustration shows the gearset case and levers as seen in the stripped chassis.



Convex Footboard of the Kelly Trucks, the Lippard-Stewart Steering Column Brace, the Buick Globe-Mounted Gear Changing Lever, and the Control Pedals, Levers and Steering Post of the Studebaker Unit Power Plant.

One of the most interesting of power plant designs is that utilized in the Studebaker three-ton truck, which can be regarded as a unit assembly from every point of view. In this the engine, clutch and transmission gearset are combined, and in addition the steering column, the clutch and service brake shafts, as well as the gearset and the first emergency brake levers are included. The assembly is mounted on three points, so that by the removal of the five bolts and the disconnection of the water manifolds and the gasoline supply pipe the whole may be removed as a unit from the chassis frame. In the two forward arms of the motor case are rings, and directly in front of the lever quadrant is a third, so that the sling chains of a



The Brake Shaft Mounting of the One-Ton Universal Wagon, the Brake Shafts of the Kissel 2500-Pound Wagon Carried on the Radius Rod, the Brake Equalizers of the Adams Machines, and the Brackets for the Flint Gasoline Tank.

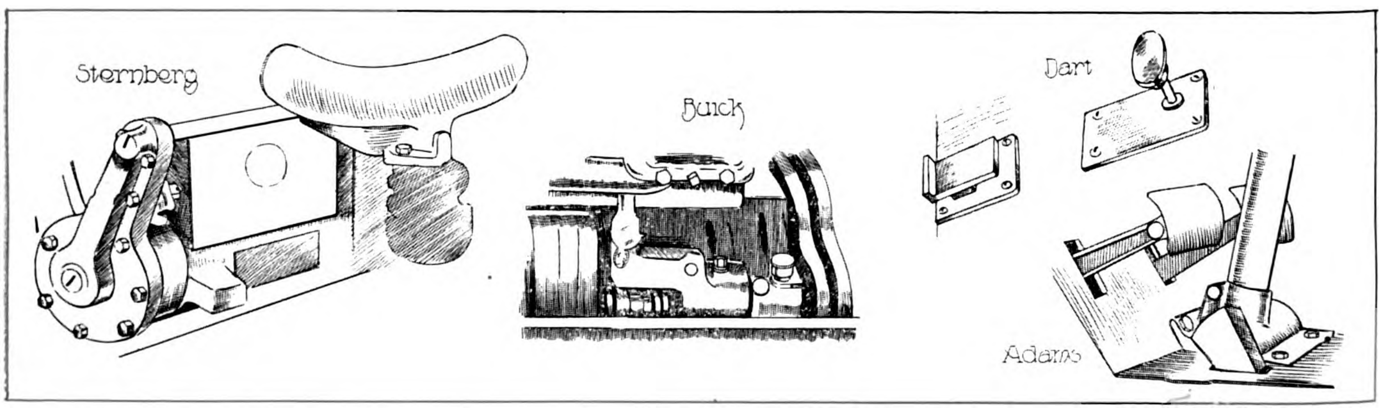
hoist may be hooked into them and the power plant lifted from the frame with the greatest ease. One of the reasons for the design is that with a number of the machines it is possible to have one or more spare motor assemblies, and in the event of need a change can be made very quickly. The first emergency brake operates on the driving shaft with the service brake, and the second lever, which is shown in the sketch, actuates the second emergency brake, which has shoes of the locomotive type that contact with drums on the rear wheels.

The brakes of the Universal one-ton worm driven wagon are the internal expanding type and the shafts are mounted in a bracket on the rear axle housing. The radius rods are very long and are swivelled in the centre of the chassis frame. The chassis centre cross member is wide and in this is an opening which permits free movement of the driving shaft. The brake shaft bracket and the rear end of the radius rod support the brake shafts, as will be seen in the illustration, and at the ends of the sleeve and the shaft are the lever arms, which operate the brake cams. The lever arms are so located that there is a direct pull on the levers, the rods paralleling the driving shaft. The location protects the levers and the rods, and all may be reached very easily in the event of need.

In the KisselKar 2500-pound wagon the brake shafts are mounted on the radius rod, the rear axle end of the rod being carried on a bearing so that it may have a vertical movement. The brakes are internal expanding and external contracting, and as the shaft ends are inside the radius rod they are fully protected, while there is a direct forward pull on the linkage to the forward shafts. This materially simplifies the construction and insures ease of adjustment of the rods should this be necessary.

The brake equalizer of the Adams wagons and trucks is carefully worked out, this being shown in the accompanying illustration. The rod from the shaft of the service brake is carried back along the left side of the chassis frame to an equalizing bar, and is so linked that the bar may have horizontal movement. From either end of the bar is a rod having yoked ends. The rear end of the left rod is connected with the left brake pull rod, and this connection is made at the upper end of a link. The lower end of this link is mounted on the left arm of a yoke carried on a chassis cross frame member. The rear end of the right rod is connected to the lever arm of a shaft, and the left end of this shaft is carried by the right arm of the yoke on the chassis frame. The right end of the shaft is mounted in another bracket on the side member of the chassis frame, and this shaft carries another lever arm to which the right brake pull rod is connected. The yoke ends of the rods are threaded on and the lever arms are clamped on the shafts so that it is possible to make any desired adjustment. No matter what the stress or the chassis distortion there is no possibility of the brake linkage being affected, and an equal pressure will be maintained on the brake, no matter what the condition of operation.

In the Flint delivery wagon the gasoline tank is carried under the driver's seat, and to install it in the



The Governor of the Sternberg Motor, the Governor of the Buick Machine, the Locking and Trip-Releasing Fuel Control of the Dart Motors and the Accelerators of the Adams Wagons.

usual manner on the chassis floorboards would mean the transmission gearset would be exceedingly difficult to reach. Not only this, it is desirable to have the tank so placed that minimized handling is insured, and to protect it against chassis strains is equally important. The designer solved this condition by placing at either side above the supporting arms of the gearset case, on the sub-frame, yokes that are bolted to the arms. The upper sections of these yokes are semi-circular, and into them is bolted a cylinder tank. The tank can be removed by loosening these bolts. It is so elevated above the gearset case that ordinary work can be accomplished without difficulty. Carrying a fuel tank on a sub-frame may appear to be an extreme precaution, but with this installation there is no possibility of strain on the container or the supply line to the carburetor.

The design of the Sternberg motor governor is somewhat out of the ordinary and it is driven from an extension of the camshaft. This governor is housed in a case installed at an angle to give a direct lead of the linkage to the valve in the intake manifold. The front plate of this housing may be removed if desired by loosening a series of cap screws without changing in any way the mechanism of the governor, and adjustment may be made with great accuracy.

The governor of the Buick delivery wagon is installed at the right side of the motor and is attached to the engine case, it having the appearance of a cylinder with the halves offset. In the installation a shaft extends through the lower section, being driven from the timing gears, and the extension of this shaft is coupled to the magneto, which is located directly in the rear. From the rear end of the governor case there is a housing that is connected with the intake manifold of the engine, and this contains the linkage with the valve. The governor is a simple diaphragm piston type and is said to be very efficient and accurate.

One of the interesting details of the Dart wagons is the foot control of the fuel supply. Instead of the usual form of accelerator lever, which is susceptible to the influence of road shock when the foot is resting upon it, the Dart construction has plunger toe and heel pedals. Normally the foot rests on both pedals when driving, and pressing the heel pedal varies the fuel. The pedal may be locked in any position, and a uniform supply of fuel insured, but when a change is desired this may be obtained by releasing the pedal by pressing the toe pedal. The pedals may be used to give the same effect as with the ordinary accelerator by exerting pressure upon both.

The Adams wagons and trucks have a foot accelerator that is also unusual in appearance, and it is located in the floorboards as shown in the accompanying illustration. The accelerator is a block that is pivoted below so as to have a swinging longitudinal movement in a slot, and it may be moved by resting the toe upon it, or it may be maintained in any position desired by placing the foot against it, this giving the required steadiness of throttle.

SALES OPPORTUNITIES ABROAD.

Bureau of Foreign and Domestic Commerce Has Information of Value to Makers.

American builders of motor trucks who will address inquiry to No. 10,998, bureau of foreign and domestic commerce, Department of Commerce, Washington, D. C., can learn the name and address of a consul who has filed with the bureau information that may develop an unusual opportunity for selling. A motor transportation company is now being organized in a foreign city for the haulage of cotton, coal, iron, machinery and heavy merchandise between the docks and the mills, warehouses and stores, and it is purposed to install an equipment of about 25 trucks with capacities from three to 10 tons, and to add to this as the needs are developed. It is desired that some of the chassis be equipped with quick discharging bodies, and some have winches installed for the handling of heavy and bulky freight. There is good reason to believe that many, if not all, of the machines will be purchased in the United States, and pending the completion of the company and the determination of its plans manufacturers can communicate with the consul and place such information as they desire at the disposal of the company.

KNOX PROVES EFFICIENT.

Meriden Concern Finds It Capable to Haul Capacity Loads up Steep Incline.

Meriden, Conn., has more than its share of hills and one of its largest manufacturing plants, that of the Parker Bros. Company, is located at the top of one of the steepest inclines in the city. This necessitates an immense amount of hard trucking on the part of the Parker company, the larger portion of which is now done by a big Knox four-ton truck, made by the Knox Automobile Company, Springfield, Mass.

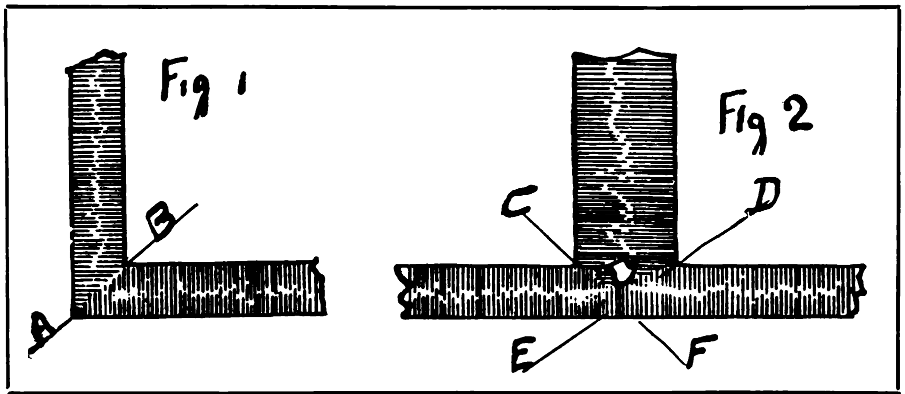
This vehicle has been in service for about 1.5 years and averages three round trips a day to the branch factory in the valley at Yalesville, three miles away, hauling its full capacity load six days a week up the steep grades to the main plant. Occasionally it is called upon to make four round trips to Yalesville and in addition to this frequently runs on special hauls to the freight house or other places between times. The repairman at the Parker garage states that the truck has scarcely seen the inside of the shop since it was first put into operation.

One of the largest sales of motor trucks to a dry goods firm was announced recently by the White Company, Cleveland, O., maker of the White, with which an order was placed by Stern Bros. of New York City for 15 machines. The new fleet will be identical in design to two White trucks which have been in the service of the company for about a year.

ALL-METAL MOTOR TRUCK WHEELS.

Riveted and Welded Types Intended to Secure Minimum Weight and Maximum Endurance and Escape Casting Defects—Carefully Developed Designs Have Overcome Faults of Cast Constructions and Minimized Road Shock Influences.

IN THE experience of the European all-metal motor vehicle wheel makers two types have been produced, the one being the casting and the other built

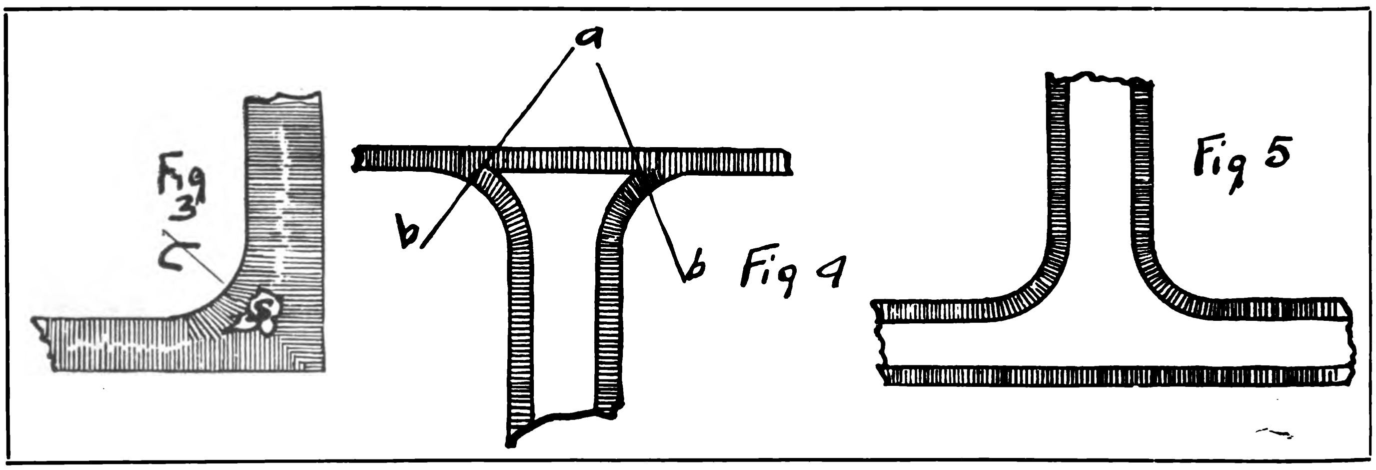


by riveting or welding stampings. The former construction has been more generally adopted than the other for a number of reasons, but it may be said that it appeared to be the cheaper and more logical to cast wheels than to build them, and there has been a very broad general knowledge of casting metals that appeared to justify the belief that such wheels could be made sufficient in every requirement.

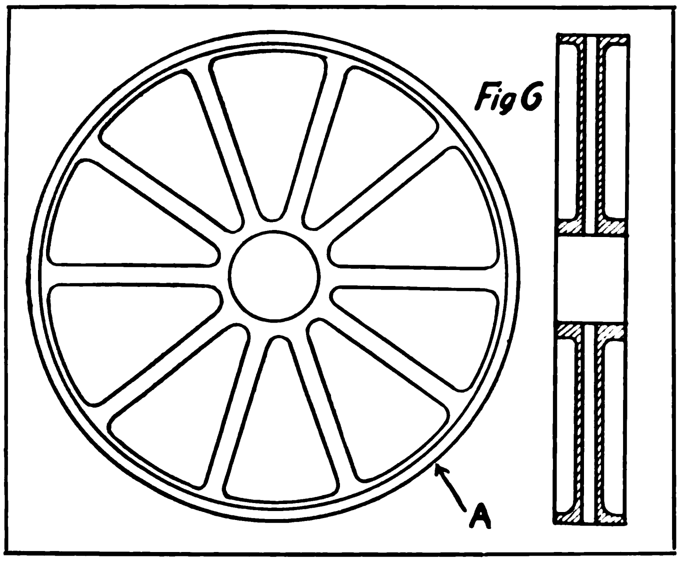
The steel wheel, so far as the design is concerned, does not appear to be a problem of unusual proportions, but it was found that it was extremely difficult to produce what would have every desired quality and be free from faults. Metal casting is an art when it becomes necessary to secure the greatest strength with the minimum of weight, because it is imperative that the material contain the elements that will resist all stresses and strains and endure a long period of service. As is well known to engineers, vibration will eventually bring about a condition of crystallization that is known as fatigue, when the metal loses its strength and becomes so brittle that it will fracture, and generally speaking this result will be realized quicker in a casting than in a forging, for the grain of the latter is finer and the better united.

The softest and most ductile metals will become fatigued, and when a steel has been treated or tempered it will have strength to resist strain and will maintain its form, but it becomes the more susceptible to the influences of vibration. In the casting of steel the metal generally cools in ratio to the proportions of the part cast, and where extreme strength is imperative uniformity of cooling is sometimes promoted by heating or by both, so that there will be a perfectly homogeneous section and there will not be structural strains due to shrinkage as the casting cools. The application of both heat and cooling influence in casting is too expensive to be considered in the production of steel or metal wheels, and with this practically eliminated, the engineer must turn to other means to bring about the strength and structural uniformity that is desired.

English engineers have sought to avoid the difficulties encountered in securing satisfactory steel castings by constructing wheels from stamped sheet steel that was riveted or welded together. The riveted wheel has not been given the serious consideration that might appear desirable from the fact that it must be pressed from sheet steel, generally rolled, and the different parts riveted. Under any circumstances the hub must be a casting, and the other sections, the spokes and the rims, must be drilled and assembled. There is always a possibility of a weakness from the rivet holes or the rivets, and there is a constant strain upon the rivets that might be expected to result in wear. While it is true that rivets could be tightened it is also equally certain that these might not be discovered until a



wheel had failed. This is not meant to imply that these wheels are necessarily weak, but it is maintained that these are not regarded as reliable as others



when considered from every point of view.

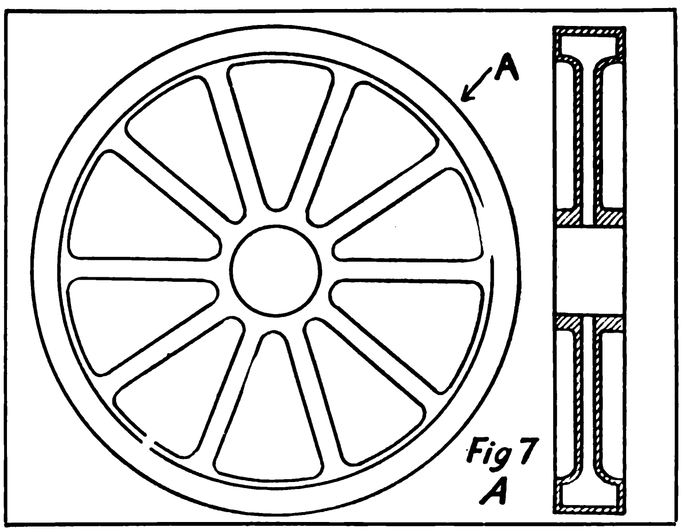
The wheel of stamped steel sections welded by the autogenous process has been built by several makers in England, and these have been found to be light and strong, having sufficient weight of metal in all parts where stress can be expected, and minimum thickness of walls has been compensated by large diameter spokes and generous rim sections. The disc and rim type of wheel, which has been used with a number of heavy machines with considerable success in England and continental Europe, and have been used in America by two builders of electric vehicles, does not appear to have met general approval, although this may be due to the lack of knowledge of the possibilities of this form of construction. The autogenous or electric processes make possible the satisfactory welding of any parts of wheels, and with this there is the strength of the stamped metal, a factor of considerable importance, to be considered. Whether or not built wheels are more costly, and whether they have greater strength and endurance, when contrasted with other types, is not known. In fact, there is very little knowledge of these forms of constructions in America, and the experience of the English builders has not been given publicity.

The European builders have turned to cast steel wheels, and the first of these were solid. One of the conditions that was experienced was the possibility of spokes being weakened from shrinkage cracks near the juncture with the rim, evidently due to quicker cooling, for these were the smallest sections. Where the wheels were in service it was found that fatigue first developed at the small section of the spoke, and this was to a certain extent overcome by webs between the spokes that were longitudinal of the rim. With the different sizes of wheels the conditions were found to vary somewhat, and with the heavy forms the Y spoke was adopted as being the better construction and having the greatest strength. From this was developed the hollow spoke and eventually the hollow rim. The Fischer wheels, made at Schaffhausen, Switzerland, and the Sheffield wheels, made at Sheffield, England, are both of the hollow spoke and hollow rim types, although the Sheffield wheels are made with solid rims as well. In this country the Shelden wheel is cast solid, the Smith wheel is cast with webbing and the Timken wheel is cast, treated to be malleable.

The material in the Fischer wheel is steel heated in an electric furnace, and the heat is regulated very accurately by a pyrometer so that the working can be observed and a condition maintained wherever desirable. The Sheffield wheel metal is also worked with an electric furnace and extreme care is taken to have the metal very pure. It is stated that a long period of experimentation was necessary to produce the quality of metal that would endure satisfactorily.

There is no question that steel wheels have within a comparatively short time attracted much attention in America, but especially from the automobile engineer. The people, however, have not had sufficient knowledge of them or their qualities to judge intelligently, and it is probable that it will be necessary for comparative service for a considerable length of time before the all-metal wheels will be generally known by their merits. Briefly, it is claimed for the metal wheel that as compared with wood it has superior strength, is lighter, that it can be made to a uniform size and there will be no variance so far as tire installation is concerned, and that it is certain to be true when made.

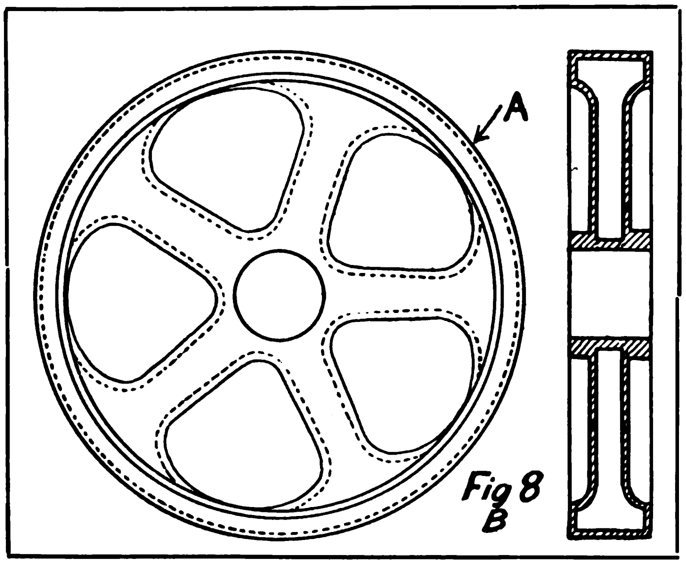
The disadvantages or possible fault in all metal wheels that have been thus far developed are excessive weight, development of cracks and non-resiliency. But it is maintained that these are covered entirely by the question of design in the cast steel wheel. It is claimed, however, that the same agencies that are developing trucks are also developing the steel wheel, and there cannot be otherwise than an improvement. The weight of the wheels is receiving an attention that



will result in construction that will have, in all probability, standards for differing designs. Designers and foundrymen are now endeavoring to obtain thinner

sections, and a wheel with a quarter-inch wall thickness is not at all uncommon.

It may be well to here point out that the require-



ments of the automobile industry have developed special metals and alloys because of the need of great strength with minimum weight, and with the perfection of these materials the results have been manifold. The possibilities have encouraged the use of such metals, the production has been increased and the prices decreased in ratio of production, the vehicles have given longer and better service, and the industry has been directly benefited. Probably the decrease of prices with increase of production has been the greatest factor in promoting the use of special metals, for in small quantities the cost was relatively large.

In the making of the all-metal wheel there is quite as much need of extreme strength and light weight as in any other form of construction, but while with the built type it is possible to have the qualities of the rolled or forged metal, that is, the finer grain, the casting must necessarily have the coarser and really weaker grain. The rolled or forged metal can be heat treated or tempered, but the only treatment practical with the casting is annealing, which will increase its ductility and cause a finer grain, but there will be reduced resiliency and less resistance to the influence of shock. That is, there will not be the property of maintaining conformation.

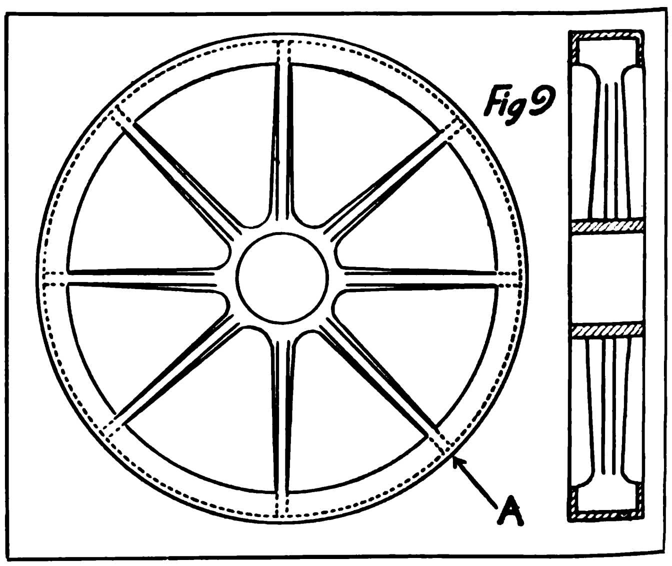
It would be possible to improve the metal from which castings can be made by the use of vanadium, titanium or nickel, which are given in the order of value, and wheels made from steels containing these elements would be decidedly stronger. The real purpose of combining one of these elements with steel is to purify it.

From the viewpoint of the foundryman, whose knowledge of metals and their characteristics is broad, the most serious problem to be considered is the development of cracks in the castings. These appear not only at the foundry, but also in service on the road. The cause can be in the metal as well as in the design, but the purpose of this review will be the better served by ignoring the metal for the time being and leaving this with specifications and dealing with design only, as the crux of the entire proposition is the design.

All iron, steel or ingot castings are composed of crystals that run as regularly in the metal as do the fibers in wood, and as the weakest points in wood are where the branches diverge from the trunk or main stem, so are the weakest points in steel or iron at the points of intersection. The crystals form regularly and at right angles with the contour of the casting at all times. This is illustrated at Fig. 1, where in a casting in the shape of an angle the crystals are formed at right angles from each side of this casting. As shown in this sketch the crystal formations meet at A-B and cause the line of weakness.

Passing to Fig. 2 a glance will show that the lines of weakness are at C-F, E-D or C-D. The crystals run regularly all the way along the straight line of the casting, but the formation of the crystals is changed on the side where there is an intersection. To overcome this irregularity of crystal formation at intersections, heavy fillets have been resorted to, but not with gratifying results. In such construction, though the crystals are formed more regularly, the amount of metal in a fillet addition, together with that caused by the lug or arm, may result in shrink holes, and the grain will appear coarser at that point. These shrink holes, as seen in Fig. 3, are very irregular in form and size, so it is apparent that fillets are a doubtful remedy, and serve the purpose but very little. But where such shrink holes may be created a core might be used to excellent advantage.

Turning to Fig. 4, in which the designs shown at Figs. 2 and 3 are combined, the core is used, and in this the change of crystal formation, and, consequently, the lines of weakness are at A-B. The crystals are regular at either side of the core and on the solid side of the casting that intersects the walls formed by the core, but the change is apparent where the walls and



the side join. At Fig. 5 is shown the ideal design without junctures or joints of any kind, such as are seen at A-B in Fig. 4. In this design the crystals are

formed regularly along the walls of the casting.

Having considered the questions of weight and lines of weakness, the vital problem of resiliency is met with. Resilience is the power of metal to assume its original shape and size after distortion by the application of force. A solid iron or steel is not resilient in the sense in which resiliency is applied, for as a mass it does not receive an impression, nor can its shape be distorted by shocks. From the viewpoint of the foundryman wrought or malleable iron is not resilient, though it may take impacts, but that only at the precise point at which the impact occurs, and but slightly return to its original shape when the forces are released. It will take a set comparatively easily, and its support will receive almost the full force of the shock.

To illustrate this point, a wrought or malleable iron ring may be struck a 50-pound blow. It will bend in the direction of the blow and the hand holding it in position does not feel the stinging pain that would be felt were the ring of a fairly high carbon steel. The steel ring, when struck, absorbs or takes up the blow and vibrates to such an extent as to cause it to bounce on its support, while with the wrought or malleable iron ring the blow is transmitted to the support. Because of the low elastic limit of malleable or wrought iron, the severe repeated shocks easily go beyond that limit, causing coarse grain and eventually fracture. A resilient wheel is less likely to develop cracks, as shocks are instantly transmitted over the whole wheel, and thus lose their force at the point of contact.

Elasticity or resiliency is very important and must receive the most careful consideration in truck wheel construction. The elastic limit in steel is dependent upon the carbon contents. It is obvious that the wheels having resilient qualities are best adapted for automobile trucks. Road shocks and impacts cannot be eliminated. They must be taken care of so as to do the least possible harm. In a wheel that is not resilient, the energy as represented by a road shock is transmitted direct to the axle, minus that which is expended in overcoming inertia or motion.

Materials having a low elastic limit are not regarded by the metallurgist or foundryman as suited for motor truck wheels any more than malleable or wrought iron is suitable for springs.

While the material of a truck wheel is very important, the design is an equally potent factor. At Fig. 6 is represented a design that will hardly serve the purpose of a truck wheel. The hollow spokes join the rim at almost a right angle, and no effort is made to eliminate the lines of weakness that are illustrated at Fig. 1 and Fig. 2. Furthermore, the overhang is twice that of the width of the rim and shocks are transmitted to only one or two spokes because of the flat shape of the rim. This wheel would develop weakness and would eventually fracture in the spoke near the rim. At Fig. 7 a hollow spoke joins a hollow rim, but in this there is no endeavor made to overcome the weakness at the joint of the spoke and the rim. But the hollow rim makes possible the distribution of the shocks somewhat over the whole rim, rather than just between two spokes. However, with this design the weakness and the eventual fracture will be at the precise point stated with reference to the design shown in Fig. 6.

In Fig. 9 is shown a wheel that has a channel section rim and an uneven cross section spoke running the full width of the rim. In this the overhang is reduced to a minimum. This rim is resilient and will not bend because of the flanges, but a blow upon a spoke is transmitted to a very large extent directly to the axle.

The channel section rim is a very important part in wheel design. A shock or blow on the rim between the spokes is immediately transmitted to the flanges and these vibrate almost independently of the wheel itself. Thus the shock energy is dissipated as it were like the vibrations at the end of a tuning fork. At Fig. 8 (hollow rim) the rim is too stiff and will not vibrate sufficiently, so that the shocks are transmitted directly to the axle. The wheel is also heavier than one of channel section.

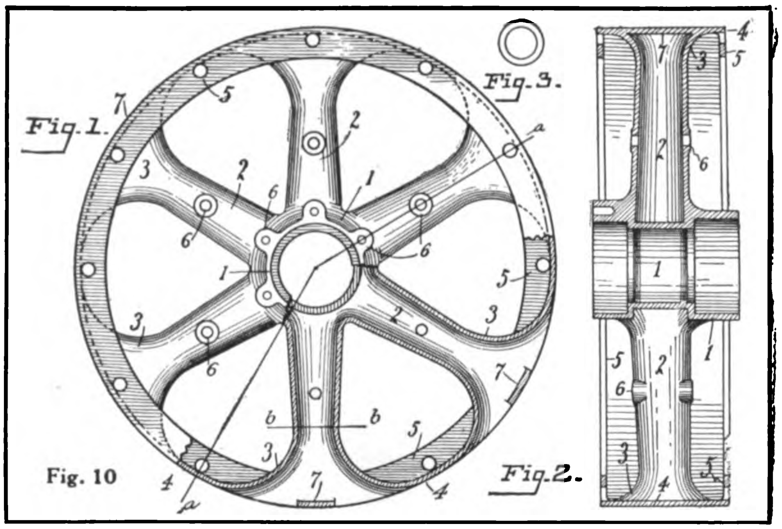


Fig. 10

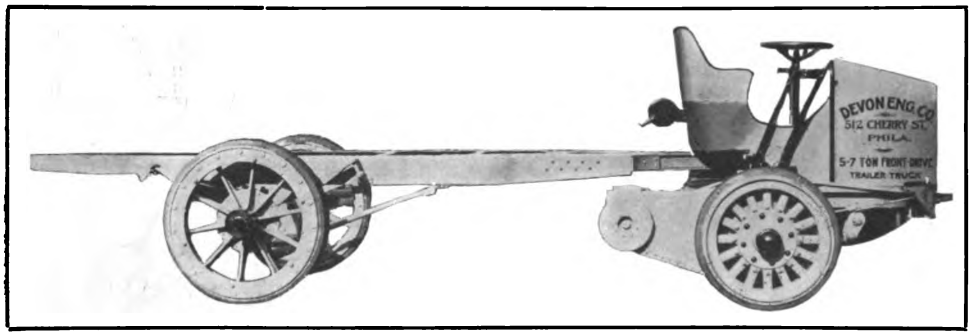
In the perfectly designed and balanced wheel shocks should not be taken up by the rim alone, but they should be distributed over the whole wheel, that is, it should vibrate, making the wheel less liable to develop cracks. In the wheel shown in Fig. 10 these fundamental qualities are embodied in the design. In this all the joints between the rim and spokes are eliminated, and with them the conditions that make for weakness in steel castings. Instead of joining the spokes to the rim of the wheel, the spokes and rim are one continuous integral part, light and of even thickness. Shocks and impacts are no more sustained by the rim alone, but are evenly distributed to both rim and spokes. There are no obstructions to the course of vibration. Were one to strike a blow at A in Fig. 10 and the vibrations are instantly transmitted to the spoke, from there again to rim, and so on. But if this spoke were at a right angle as in Fig. 6 or Fig. 9 and a blow given on either rim at A, the vibrations would

stop at the spoke. The spokes cannot swing with the rim, as it were. The rim would vibrate in one direction, and the spokes in another. The design of this wheel is most ideal, and its weight is somewhat less than that of a wood wheel of the same carrying capacity. These wheels can be made to the S. A. E. standards and will take any type of S. A. E. flange-attached tire.

DEVON FRONT-DRIVE TRACTOR.

Chassis Designed for Use with Special Equipment or Converted Animal Wagons.

The Devon Engineering Company, Philadelphia, Penn., is building a power equipment that may be used with special body construction, or with converted animal wagons, the machine being a chassis containing a power plant that is mounted on two wheels to which the power is transmitted. The chassis is constructed as a unit and to this a frame, rear axle, wheels and body may be coupled, the proportions of the body and capacity depending very largely upon the requirements of the purchaser and the varying conditions under which his particular work must be performed.



The Front Wheel Driven Devon Chassis, Adapted for Regular Equipment or for the Use of Converted Horse Vehicles.

The power plant is conventional, being a four-cylinder water-cooled, four-cycle gasoline motor, carried under a hood, and this is mounted in the frame, which also carries the radiator, gasoline tank and the usual auxiliaries. The chassis is steered by a large hand wheel, the attached gear and body being pivoted so that the chassis may be turned to any desired degree. The power is applied to the chassis wheels in whatever ratio may be desired. Back of the driver's seat on the chassis is the turntable, to which the body gear is attached, this taking the form of a steel frame attached to a dead axle fitted with steel wheels. The wheels may be shod with steel or rubber tires. On this axle and frame is mounted the body. It is entirely practical for a purchaser to adapt horse wagons to use with the chassis by the use of comparatively inexpensive frames. The chassis is regarded as having sufficient power to haul six tons under all working conditions, and while the speed is low as compared with machines that are sprung and have rubber tires, the capacity is relatively large and the cost of maintenance is small. The greater part of the weight is carried on the dead rear axle and the expense for tires is minimized. With the front-wheel drive it is claimed that skidding is practically negligible.

THE HORSE, TRUCK AND TRACTOR.

An Analysis of the Cost and Productiveness of Types of Highway Vehicles.

"The Horse, Truck and Tractor" is the title of a book issued from the press of F. G. Browne & Co., Chicago, Ill., which was written in collaboration by Herbert N. Casson, R. W. Hutchinson, Jr., and L. W. Ellis. As the title implies, the book is in three parts, the first of which, by Mr. Casson, is devoted to the horse. This article estimates the economic value of animals, shows that the value has been largely and the numbers considerably increased during a comparatively brief period, and that when measured by known standards the horse is a very costly creature. Mr. Hutchinson writes of the experience with and the possibilities for economy with the utilization of trucks. He included in his consideration a considerable number of illustrations of efficiency and estimates of operation costs for differing services. Mr. Ellis has intimate knowledge of the production and use of farming power machinery, and he deals with tractors, the actual value and the practical economy of road trains being set forth with much care. This is the first work that considers highway transportation with reference to all three practical forms of haulage. It has merit in that it demonstrates very graphically the enormous price paid for handling and freight carrying by the nation, and suggests the material saving that could be made with motorized transporting facilities.

The city council of Minneapolis, Minn., has before it an ordinance that, if it is passed, will limit the weight of loads that may be hauled through the streets to 15,000 pounds. This ordinance is intended to apply to all vehicles, and the reason to justify it is the wear of heavy vehicles on the paving. But, strangely enough, the measure does not limit the width of tires, and this is an argument that is made by the owners of trucks against its passage.

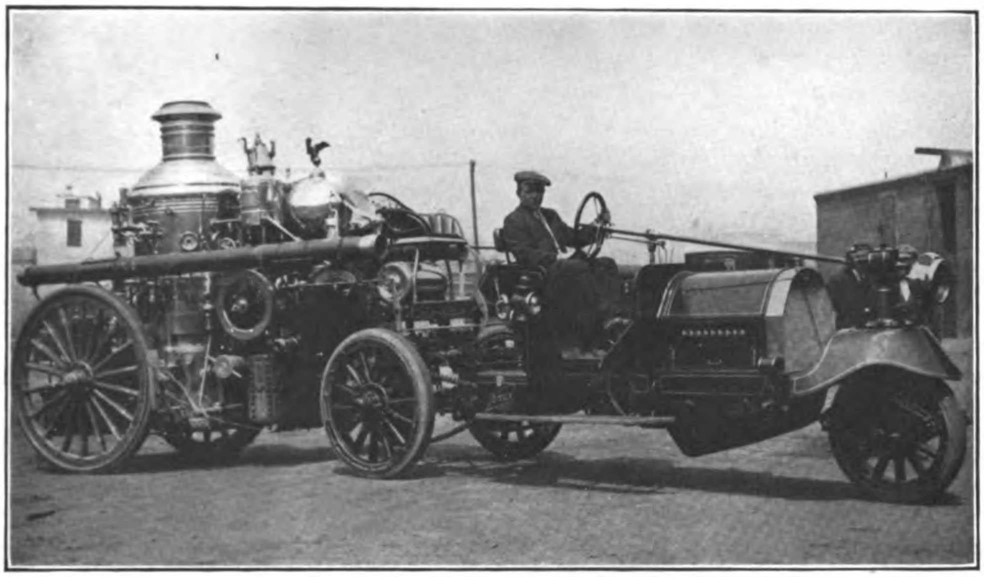
The Blaugas Company of America has begun to manufacture at Long Island City, N. Y., a liquid gas known as blaugas, which has been used for a considerable length of time in Germany and is said to be efficient and economical. The Atlantic Blaugas Company has used this fuel with satisfaction in the operation of its motor vehicles. The fuel is not yet produced in commercial quantities, but it is obtainable by those who care to experiment and determine its value.

VALUE OF KNOX-MARTIN TRACTOR.

People of Tarrytown, N. Y., Quickly Appreciate Its Economy and Efficiency.

An interesting example of the rapid education of the public with respect to the economy and efficiency of motor driven fire apparatus is noted in the experience of the department in Tarrytown, N. Y. About a year ago, after some little discussion, the town voted an appropriation for the purchase of a Knox-Martin tractor, made by the Knox Automobile Company, Springfield, Mass. This year, on a question of appropriating $13,800 for the purchase of additional motor equipment, the favorable vote was practically unanimous.

Not only was the tractor successful in handling a series of bad fires during the past season, thereby convincing the voters of Tarrytown, but the neighboring towns of North Tarrytown, Dobb's Ferry, Nyack and Briar Cliff Manor have appropriated a total of $35,000 for the purchase of similar apparatus. Several municipalities throughout the country are contemplating the installation of this type of vehicle, an accompanying illustration showing one attached to a steam fire engine in Providence, R. I., where it was demonstrated for 10 days with the result that the city council has been asked for an appropriation for its purchase.



Demonstrating Knox-Martin Tractor with Steam Engine in Providence, R. I.

MOTOR VS. HORSE COST.

Interesting Comparative Figures Prepared by Fire Department in Springfield, Mass.

A table prepared by the board of fire commissioners of Springfield, Mass., showing the comparative cost of upkeep between motor and horse drawn apparatus for the year ending March 31, has demonstrated to the satisfaction of the commissioners that the city is saving thousands of dollars annually in the maintenance of the fire department since the introduction of motor driven apparatus. The average cost of maintenance for the seven motor pieces used as a basis of comparison was $161.89, and the average number of alarms answered by each piece was 140, while the average cost of the two-horse drawn pieces of apparatus used as a basis of comparison was $524.18, and the average number of calls answered was 125. The actual figure for each motor wagon would have been lowered considerably if the amount of money spent for the rebuilding of two motor trucks had not been included.

It is of interest to note that, while the cost of maintenance has been lowered since motor driven apparatus has been introduced into the department, the amount of fire loss has been correspondingly lessened. The annual saving resulting from the quick response to alarms, it is estimated, would pay a considerable portion of the cost of maintaining the department.

According to the table the cost of maintaining truck 1 from April 1, 1912, to March 31, 1913, was $280.32, while the number of runs made during the period was 148. Of this amount, however, about $225 was expended for changing the location of the batteries and other improvements. The cost of the other

pieces of motor apparatus was as follows: Truck 10, $65.21; hose 1, $680.71; hose 7, $31.86; hose 8, $37.40; hose 12, $22.17; hose 13, $15.61. With hose 1, an expense of $625 for rebuilding the truck was added. During that period truck 10 made 165 runs; hose 1, 192; hose 7, 216; hose 8, 110; hose 12, 109; hose 13, 63. It is found that if the sum of $845 spent for rebuilding the two pieces, which occurs at intervals of several years, were deducted from the total, the average would be less than $50, which represents the real cost of upkeep. The expense of maintaining truck 8, horse drawn, for the year, was $620.42, and of hose 10, $427.94. Truck 8 made 107 runs and hose 10, 143.

KisselKar Combination at Work as Street Sprinkler.

NEW STREET CLEANING MACHINE.

Combined Flusher and Sprinkler Produced by Kissel Motor Car Company.

Accompanying illustrations present the new patent combination uniform pressure street flusher and sprinkler recently placed in the market by the Kissel Motor Car Company, Hartford, Wis., maker of KisselKar trucks and pleasure cars. The design is such that it is expected to afford a satisfactory means for cleansing city pavements, and the flushing and sprinkling mechanism is controlled by hand levers under the driver's control, and so arranged that it can be changed from one to the other in an instant.

The chassis is that of a regulation KisselKar three-ton truck, fitted with a 1000-gallon galvanized steel tank. Pressure is produced by taking the water by gravity from the bottom of the tank into a two-stage centrifugal pump directly connected to the motor, and it is maintained that this may be from 20 to 60 pounds according to the speed of the engine. The water is then forced into distributing pipes and out through adjustable nozzles for flushing and through two pipes to sprinkling attachments of the vehicle type. It is claimed that the same pressure can be maintained when the tank is partially full as when entirely filled, making it possible to secure the benefit of all the water contained in the tank.

The sprinklers are so arranged that they will sprinkle the full width of a 60-foot street from curb to curb, or they can be closed down to accommodate 20, 30, 40 or 50-foot streets at will. They will sprinkle both sides at once or either side separately, making it possible to operate the machine successfully where the traffic is heavy. One tank of water will sprinkle seven to eight blocks of 50-foot roadway, or will flush a distance of 3.5 blocks.

ADOPT CHRISTIE TRACTOR.

Central Station in Pawtucket Has First Machine of This Type in Rhode Island.

Following its plan to eliminate horses in the fire department as rapidly as possible, Pawtucket, R. I., has installed a 90 horsepower Christie front drive tractor on its hook and ladder truck at the central station, this equipment replacing a three-horse hitch. The installation is presented in an accompanying illustration, and is the first of this character in Rhode Island, although it is understood that another will soon be placed in Woonsocket.

The tractor itself is in all respects the same as those utilized in New York City, which were described in full in MOTOR TRUCK last July, and was designed and installed by Walter Christie, the well known automobile racing driver, who has long been a strong advocate of the front drive principle. The motor is a four-cylinder unit, with bore of 5.5 inches and stroke of seven.

This construction is rigidly bolted to the forward end of the truck, giving a slightly longer wheelbase than when it was utilized with horses, this now being practically 26 feet. Of course the rear wheels are steered by tiller as with the ordinary vehicle of this type, and the driver must govern his turning not only to accommodate the long wheelbase, but some 12 feet of overhang on the ladders. Although Pawtucket is

Indicating Value of KisselKar Flushing Apparatus.

well supplied with what may be regarded as crooked streets and the turning radius afforded on many runs is often very limited, the driver asserts that the combination is handled as easily as with horses.

NOTES FROM VARIOUS CITIES.

KisselKar Ambulance in West—The Kissel Motor Car Company, Hartford, Wis., maker of KisselKar trucks, recently made sales of motor ambulances to the cities of Milwaukee, Wis., and St. Paul, Minn.

Georgia City Adds to Equipment—Atlanta, Ga., is soon to purchase a triple combination pump, hose and chemical motor car, having 700 gallons capacity.

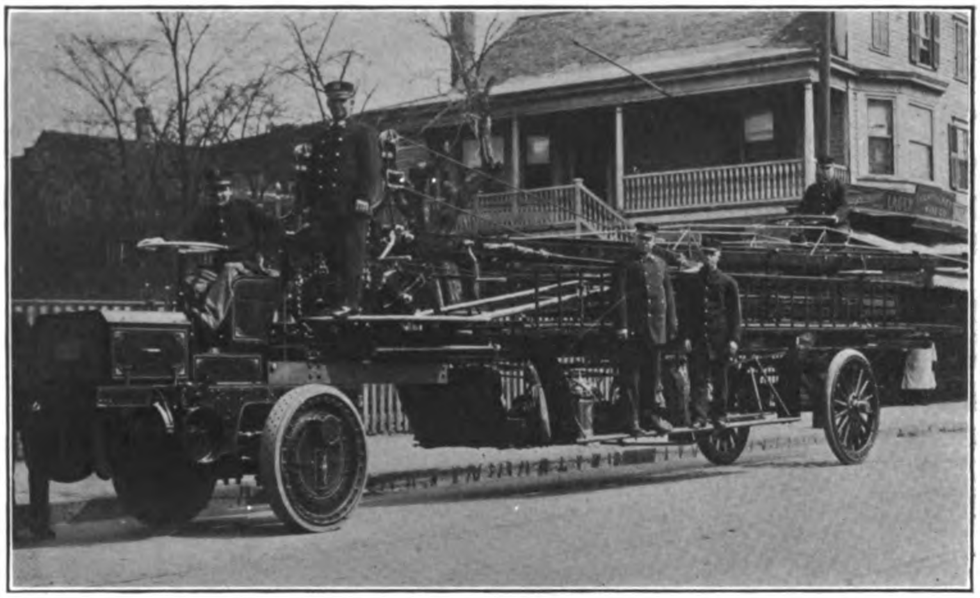
Street Watering Machines at St. Louis—A contracting company that undertook to water the streets of St. Louis, Mo., purchased 10 Smith-Milwaukee trucks, made by the A. O. Smith Company, Milwaukee, Wis., and these machines have performed the work of 50 teams. Two others have been purchased and this year the 12 vehicles will do all the work of watering the streets. Naturally, the number of drivers has been cut down by 38 and this alone is a decided economy, although by no means the most important.

Water Department Purchases Motors—The water board of Hartford, Conn., took a progressive step recently to facilitate the outside business of the department, when it authorized the purchase of motorized equipment. The report favoring the purchase, presented by Commissioner J. H. Root, recommended the purchase of a five-passenger, 50 horsepower touring car; a five-ton truck; a 1.5-ton truck and a .75-ton truck. The machines to be purchased will be Pope-Hartfords, made by the Pope Manufacturing Company of that city.

Akron to Give Big Order—The city of Akron, O., has received sealed bids for three triple combination fire engines, chemical and hose wagons, an 85-foot extension aerial truck, two combintion chemical and hose carts, a supply wagon and three tractors, to cost $65,000.

Des Moines Installs Four Machines—The city council of Des Moines, Ia., has authorized the execution of written contracts for the purchase of new fire apparatus of the motor type. One will be type 14, six-cylinder motor service hook and ladder truck, 105 horsepower, while another will be a tractor of 105 horsepower, six-cylinder, to be attached to the aerial truck. Both of these machines will be purchased of the American-LaFrance Fire Engine Company, Elmira, N. Y. In addition to these the city will purchase two six-cylinder motor driven combination hose and chemical wagons of the Seagrave Company, Columbus, O.

Many Cities Buy White Trucks—High speed chemical and hose trucks are increasing in popularity with the fire chiefs throughout the country and many municipalities are motorizing their equipment as fast as appropriations can be obtained. The large number now in use emphasizes their great value in protective work. Chicago has 11 White six-cylinder 60 horsepower fire patrols, made by the White Company, Cleveland, O., in the service of the insurance underwriters. Recent sales of White trucks were made to the cities of New Castle, Penn.; Dover, N. J.; Easthampton and Malden, Mass.; Sioux City, Ia., and Poughkeepsie and Mount Vernon, N. Y.



Christie Front Drive Tractor Installed with Pawtucket's Hook and Ladder Truck.

Five Cole Cars for Philadelphia—That the gasoline pleasure car is more and more to become a space eliminator for fire department chiefs is shown by the order recently placed by the Philadelphia fire department with the Cole Motor Car Company, Indianapolis, Ind., for five Cole roadsters for the use of battalion chiefs.

Buick in Boston Service—The Buick Boston Company, Boston, Mass., has delivered four 1913 roadsters to the Boston fire department. The machines are equipped with fire fighting equipment and an advantage is obtained in that the local branch of the Buick company is able to supply at a moment's notice any repair parts that may be needed.

GARAGE MEN ORGANIZE.

Owners of Massachusetts Public Service Stations Form New Trade Association.

The Massachusetts Garage Association has been organized for the purpose of generally promoting the interests of the owners of public service stations in that state. The organization as formed is composed chiefly of men doing business in Boston and vicinity, but the intention is to have the membership include every owner or manager of a public garage in the state, provided that the applicant can be recommended by members. The activities of the association will be quite as interesting to owners of wagons and trucks from the fact that a very large number of the machines now in service in Massachusetts are stored, and often maintained, at public stations. One benefit provided for is the exchange of information that would be of value, another is the maintenance of charges for service, another is to insure the public that there will be uniformity of work, and it is purposed to impel the confidence of the people through satisfactory attention. In other words, the fact that a garage is controlled by a member of the association is expected to assure the people of the best of service and reasonable charges for work and supplies.

The officers of the association are: President, J. S. Hathaway, manager of the White Company's garage, Boston; vice president, J. E. Savell, of the Motor Car Service Company's garage, Boston; secretary and treasurer, Chester I. Campbell, 5 Park square, Boston; directors, V. A. Charles, Inter-State Automobile Company, Boston; F. W. Boynton, Hyde Park Auto Station, Hyde Park; John F. Fleming, Brookline; C. E. Harris, Harris Garage Company, Easthampton; J. W. Robertson, Robertson Motor Car Company, Taunton; R. H. Hartley, Church Street Corporation, Lowell; J. E. Savell, Motor Car Service Company, Boston.

BOSTON'S 1914 MOTOR TRUCK SHOW.

Will Take Place from March 17 to 21 Inclusive, and Follow Exhibition of Cars.

The third annual show of motor wagons and trucks of the Boston Commercial Motor Vehicle Association will take place in Mechanics' building, beginning Tuesday, March 17, 1914, and will be concluded the evening of Saturday, March 21. The association at its meeting May 1 decided almost unanimously to hold the exhibition, and it is stated that the expression of the members unable to be present was equally as favorable. While the announcement was made at the show last March that there would be an exposition next year, this was not formally determined until the meeting.

When the pleasure car and service wagon shows were divided in 1912 an interval of three days was arranged between the exhibitions, which was expected to benefit the exhibitors in that it would give them sufficient time to remove the cars and arrange the displays of wagons and trucks, and allow the dealers an interval to take care of business detail that had been neglected during the showing of the pleasure machines. This, however, necessitated a Sunday intervening in the show, and it was found that this required more time than many of the factory representatives could consistently take.

It was believed that the plan as decided on will eliminate at least three days of the time that had been required, and would be much more satisfactory to the exhibitors as a whole, and that there would be a generally larger exhibition. General Manager Chester I. Campbell has already begun preparation for the 1914 show, and he has a considerable number of applications for space. Manager Campbell, in a statement issued by him, predicts that the truck show for the coming year will be the largest and most successful ever held in Boston.

WHITE OMNIBUS SERVICE.

Eight New Passenger Carrying Machines Installed with the Pittsburg Auto Transit Company.

Eight new vehicles with omnibus bodies made by the White Company, Cleveland, O., for the Pittsburg Auto Transit Company, Pittsburg, Penn., were placed in service May 1. The bodies, which strongly resemble street cars, were built by one of the largest street car builders in the country. The design, however, is such that they are held to be much more comfortable in riding.

The machines are of the pay-as-you-enter type and have seats for 34 passengers. They are built with six-cylinder, 60 horsepower motors, giving them an abundance of power for the steep grades in Pittsburg. Passengers will be carried between the downtown business district and the Highland park residential section. The vehicles were prominent in the display at the recent truck show at Motor Square Garden, Pittsburg, where they attracted much attention.

A factory is now being fitted at Yonkers, N. Y., where this year, if the present plans are realized, 40 steam freight carrying trucks will be built for the Bell & Waring Co., of New York. The company is capitalized for $25,000 and it succeeded the American Motor Freight Company. The company is controlled by Harvey W. Bell, Harry G. Waring and Howard C. Phillips. Having worked out extensive experiments with two machines, manufacturing has been decided on. The truck, which will be known as the Bell, will follow closely to accepted design in every respect save the power plant. The engine has several novel features and crude oil will be used for fuel. It is believed that this form of propulsion will be very efficient, and that the low cost of fuel will be a factor of considerable importance in the operation expense.

FOREIGN TRUCK NOTES OF INTEREST

IMPORTANT CONFERENCE PLANNED.

British Government Officials and Commercial Representatives to Discuss Motor Transports.

An imperial conference will be held at London, England, during July for the purpose of dealing with the question of motor transport, including all the industrial uses of motor vehicles. Invitations to attend the conference are being sent out to all parts of the Empire and it is hoped that the government departments of all the colonies interested in the development of road transport will be represented. It is expected that representatives of chambers of commerce, boards of trade, agricultural and planters' societies, municipal and road authorities and important concerns in the engineering and motor trades will be present.

According to present arrangements, it is expected that Prince Arthur of Connaught, who is president of the conference, will receive the delegates July 18, while the following day they will visit the industrial motor vehicle exhibition organized by the Society of Manufacturers & Traders, scheduled to open that date at Olympia. During the course of the conference the delegates will visit garages, depots, etc., where industrial motors are operated in considerable numbers. The following subjects will be discussed at the conference:

The question of fuel supply; present needs and future prospects; the possibility of creating adequate supplies within the Empire.

The consideration of the problems of imperial military motor transport with special reference to the production of types of vehicles, useful both for military work and for industrial work in the dominions and colonies.

The organization of motor transport systems for the carriage of goods, and their value to the mercantile life of the community. The adaptation of existing methods of delivery required to enable traders to take full advantage of the capabilities of mechanically propelled vehicles.

The relations between the British manufacturers and buyers overseas. Desirable arrangements for satisfactory supply, agencies, etc.

Road transport in cities. The carriage of passengers and the municipal uses of motor vehicles. Fire fighting and ambulance services. Postal services.

Rural transport and the uses of the motor to the agriculturist.

THE LACRE POLICE PATROL.

Some Points in Which English Design Differs from Accepted American Practise.

An accompanying illustration presents a motor drive police patrol made by the Lacre Motor Car Company, Ltd., Letchworth, England, which is of particular interest because of the points in which it differs from what has come to be regarded as standard practise with such vehicles in this country. The chassis is that of a regulation 30 horsepower Lacre, on which the company installs its two-ton truck bodies, and it also is utilized for ambulances, mail wagons, etc.

It will be noted that the exterior of the body is without windows. The prisoners are placed in cells along either side of a corridor, extending from the back of the driver's seat to the door at the rear. Ventilation is provided by barred openings near the top of the cells, the roof over the corridor and in the rear door. Two steps lead from the ground to a landing at the rear and on either side of this platform is a seat for an attendant. Other policemen may be accommodated beside the driver or along the running boards at the side.

This type of vehicle not only serves as a patrol wagon in making arrests, but is used as a prison van, the cells being arranged so that it is possible to transfer dangerous criminals or even insane persons without endangering themselves or others. The car illustrated was one of the first supplied to the Glasgow corporation, and is considered satisfactory in every respect.

Lacre Police Patrol in Service in Glasgow, Scotland.

DUTCH MOTOR TRUCK TRIALS.

Twenty-Four Machines Take Part in Automobile Club of Holland's Contest.

The first official commercial motor vehicle trials in Holland, under the auspices of the Automobile Club of Holland, came to an end early last month, although at this writing there are no data available in this country from which to judge of the results. The cars were loaded to rated capacity with bags of sand and the daily mileage was such as to give them tests calculated to demonstrate their availability for cross country work. Incidentally, there was some evidence that the roads and bridges, particularly the latter, were in a condition calling for decided attention if motor

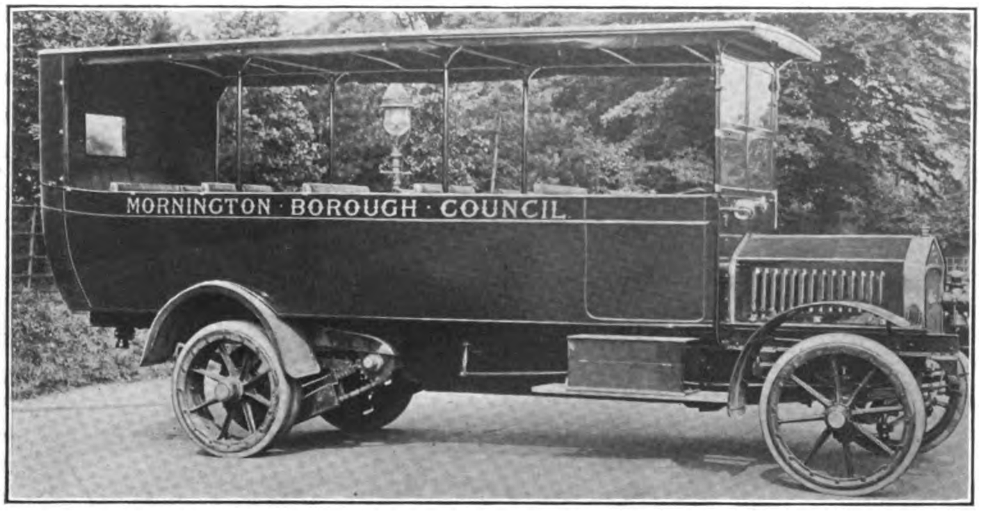
trucks are to be used in general haulage in that country.

The cars taking part were as follows: Mulag, five tons; Bussing, 4.5; Adler, four; Saurer, four; Daimler, four; Bergmann, four; Saurer, four; Lloyd, 3.5; Benz, 3.5; Bussing, 3.5; Delahaye, 3.5; Panhard, 3.5; Mulag, 3.5; Opel, three; three Dietrich, three tons each; N. A. G., three; Benz, 2.5; Thornycroft, 2.25; Saurer, two; Adler, 1.5; Fiat, 1.5; N. A. G., 1.25. Opportunity was had to exhibit the vehicles to prospective purchasers and others interested at several points along the way.

INTEREST IN THE CHAR-A-BANC.

British Concerns Actively Demonstrating This Type of Sight-Seeing Vehicle.

While the type of motor 'bus designated as char-a-banc has proven satisfactory abroad in districts in which it has been found desirable to afford means for passenger transportation where the traffic does not warrant the construction of railroads, it is noticeable that many of the British makers are seeking to develop it along other lines. During the past few months several of these vehicles have been demonstrated in the north of England, Scotland and Wales with a view to interesting local concerns in investing in a proposition calculated to increase their sight-seeing business in the sections most often visited by tourists.



Albion Pay-As-You Enter Type of Char-A-Banc as Designed for New Zealand Service.

An accompanying illustration presents an Albion char-a-banc, made by the Albion Motor Car Company, Ltd., Scotstoun, Glasgow, Scotland, which has been in service in New Zealand for some little time. It will be noted that complete protection is afforded both driver and passengers, the roof and side curtains being arranged so as to provide against all classes of weather conditions. The interior is designed to accommodate 25 passengers and the vehicle is what is termed the pay-as-you-enter type.

The present activity of the manufacturers along this line is based upon the suggestion that with the possession of a car of this character, hotels or inns in the tourist districts are able to offer special inducements in the way of providing attractive means of conveying their guests to points of interest, etc. Particular attention is given to the matter of spring suspension, upholstery and other appointments making for easy riding qualities.

STANDARD LOADING SYSTEMS.

Prominent British Engineer Suggests Importance of Giving Subject Consideration.

It is more or less well known that foreign business men, particularly in Great Britain, apparently have given little consideration to the question of loading and unloading, and until very recently there has been little disposition on the part of the manufacturers to assist them in solving the problem. It is understood, however, that several of those engaged in the business of producing bodies for commercial vehicles have taken up the matter recently, with a view to preparing blue prints and specifications and presenting these to prospective purchasers of chassis in an endeavor to provide that which shall meet the peculiar requirements of the individual installation.

A further indication of the importance attached to this subject at present is found in a recent article in the Commercial Motor, a British print, devoted to the mechanical transport, by Sir John H. A. Macdonald, an English engineer of wide repute. The article also is of interest as suggesting the methods now in vogue in that country. He says in part:

We are naturally a jog-trot nation. Once settled in a groove, we remain in it, and frown on all advice which tells us that our groove is obsolete, and that we suffer loss by complacently staying there. Who does not remember how, for nearly half a century after steam cranes were established on our quays, vast quantities of luggage were carried on men's backs at ports like Dover, Folkestone, Holyhead and Kingstown, from shore to steamer and from steamer to shore, when they could have been picked up in bulk and transferred direct without any difficulty? Either there was no imagination, or imagination was crushed by the spirit of routine. This is but one illustration of such ways of doing the system under which breaking bulk was the rule, transit in bulk from start to finish of journey being the exception. Is it to be the same when the road wagon that conveys goods carries with it the means of moving goods in bulk from wagon to train and from train to wagon? Are goods going by rail still to be put through three loading operations before delivery at their destination? Are they to be delivered to the railway by being put down piecemeal on loading banks and lifted into railway wagons, while the power to transfer them slumbers uselessly under the motor bonnet, and is the same primitive process to be gone through at the arrival station when the goods are to be transferred to motor wagons for delivery? Judging by the past it is quite conceivable.

Every day's delay will make the standardization more difficult, and absence of standardization spells evil. For it is indeed certain that without organization between the two modes of transit no uniformity will be established, and if uniformity be not established, improvement will be delayed, with the result that in the meantime much capital will be wasted in un-

suitable plant, and time and money will be daily wasted in carrying on a service which is not the best as regards either economy or efficiency.

Of course it will be said that there is a large quantity of plant, both on the rail and on the road, which might have to be altered or even scrapped, if a general system were devised and adopted. But is it not well worth considering whether this is not the best and the cheapest course in the end? Surely we may learn the lesson that our trans-Atlantic friends have taught us, that to scrap what is not the best obtainable is a paying policy. It is earnestly to be hoped that commercial motor manufacturers and railway engineers will now—today—take up this question and deal with it comprehensively and thoroughly. The devising of a system, where at present there is no system, is of importance to the public whose work has to be done, and to those who undertake to do it. It would be well if they would combine and offer a handsome set of premiums for the best designs for transit of goods from power road vehicle to goods train and vice versa, without delays in transhipment, and without the damage which too often is the result of breaking bulk. The most rapid and convenient system must be the cheapest, and if it were reached would soon repay the cost of a change of appliances.

To the writer the system which suggests itself as most likely to prove successful is one in which the body of motor wagon can be moved horizontally on to the railroad truck, the wagon's motor power being used to draw it off the one on to the other. The frame of the motor wagon and the floor of the truck would have a set of rollers projecting slightly above the floor, and the load would be hauled over the rollers, as is done in a hearse when a coffin is rolled in and out of it. The motor would be used to warp the load on and off by a small capstan drum and wire rope. The detail in doing this should not present any difficulty. It would, of course, be necessary to have the two floors at nearly the same level when brought together; but this could be accomplished in the same way as is now done for running gentlemen's carriages or furniture vans on to railway trucks.

It will be seen also that such an arrangement would be most convenient for the merchant who sends goods out of his premises, whether to go by road or rail. He would be able to use one frame and motor to run two goods carrying bodies, the second one being loaded while the first was out for delivering, the empty body being brought back and run off to be reloaded, and the loaded one run on to go out for the second delivery. Thus one machine would do double haulage work and this would reduce cost.

But whatever may be the system to be adopted, what it is desired to press is that there should be a system, that it should be a general system, and that it is false economy to have no system in which the great conveniences of the power vehicle are utilized for rapid and easy transfer of goods in bulk. Shall the appeal be made in vain to the Commercial Motor Users' Association to take this matter up without delay, and to have it dealt with as its importance demands? Every day that passes without its being given practical attention will make it more difficult to deal with.

GENERAL NEWS FROM ABROAD.

British Truck Show—The Society of Motor Manufacturers & Traders in Great Britain is organizing an international commercial vehicle exhibition to be held at Olympia, London, England, beginning July 19. It is anticipated that all the leading gasoline, steam and electric trucks made or represented in the United Kingdom, will be on display, as well as a complete line of accessories adapted for these machines.

Public Vehicles in Australia—The postoffice department in Sydney, Australia, is using two two-ton motor trucks for conveying mail matter in bulk from the wharves to the postoffice and to the railway stations. Plans are being made for the addition of several 16 horsepower closed vans of 1000 pounds capacity for collecting and transporting parcel post packages in and around Sydney. The city corporation now utilizes four five-ton street cleaning machines and two four-ton refuse wagons, and these has proven so satisfactory that several more will be ordered.

Truck Trials in Belgium—The Royal Motor Club of Belgium has revived its plan to hold an international competition for freight automobiles some time during the current year. It is several years since similar trials were held in Belgium, although an unsuccessful attempt was made in 1912.

Servian Military Commission—The Servian ministry of war is to send a military commission to the various automobile producing countries for the purpose of selecting the type of motor truck best adapted to the requirements of the Servian army. An appropriation of $2,000,000 has been made for the purchase of vehicles, and delivery will be requested as speedily as possible after orders are given.

Germany Needs Skilled Labor—According to the Borsen Zeitung, a German newspaper, German automobile manufacturers are exceedingly busy and complaints are being made as to the lack of skilled workmen. The home demand is increasing rapidly, and during the first two months of 1913 the exports to Russia and Argentine nearly doubled, while those to Belgium were trebled.

State to Establish Motor Lines—The government of Saxony, Germany, contemplates the creation of a network of state motor lines within the kingdom, provided the necessary appropriation can be secured from the parliament. The success of similar lines in Bavaria, which in some cases has resulted in the complete substitution for railroad, has carried much weight with the Saxon officials.

Transportation of Grapes—Several vineyard owners in Mendoza, Italy, have adapted the motor vehicle for the transportation of grapes. The main feature of the construction lies in use of a large air tight tank, located so that the load is carried on the rear axle. This effectually protects the grapes from the ravishes of insects during transport.

Road Construction in India—Owing to the increased use of motor vehicles of all types in India, in which the American product is well represented, the government of India has allotted a sum of 3,000,000 rupees ($973,300) to be used in the construction of roads. It is understood that this is but a beginning and that the total amount eventually to be expended in this work will reach 35,000,000 rupees ($11,355,200). Following this announcement comes the information that the market in Burma is particularly promising.

Electric Refuse Wagons in Paris—The municipal council in Paris, France, is giving a new electric front drive refuse wagon an official test, the reason for this action lying in the difficulty of securing a gasoline machine which will operate economically at the low rate of speed necessary for the collection of garbage. The tank body is made entirely of metal, the cover being in four sections, so that it is unnecessary to open but a small portion at any one time.

New Commercial Car Accessories

Lee Grease Pot.

H. B. Lee of New London, Conn., is marketing a grease pot which is designed for filling differentials, transmissions, etc. The pot is mounted on a board, eight by 20 inches, and its body is seven by seven inches of cast iron. The plunger is six inches in diameter and its displacement is such that a large amount of lubricant is forced quickly to the part. The plunger is retained by a crossbar, hinged to the pot at both ends, although either side may be removed. When the cylinder is filled with grease the plunger member is closed down and the screw turned. This forces the lubricant through a flexible metal tube to the part to be filled. The Lee grease pot is made in two styles, one for light grease and oil, and the other for heavy lubricants.

Kennedy Carburetor.

The elimination of springs, etc., easy starting in all temperatures, simplicity of adjustment and fireproof construction, are features claimed for the Kennedy carburetor, manufactured by the L. D. Robbins Company, Lynn, Mass., for which F. Shirley Boyd, 903 Boylston street, Boston, is agent. There are but two adjustments, high and low, and a single air inlet. The latter is provided with a full size hot air tube leading to the exhaust pipe of the motor and in the event of a backfire the danger of fire is reduced to a minimum. Easy starting qualities are secured through an accumulation of fuel below the gasoline level, which provides a rich mixture. This puddle forms automatically on stopping the motor. One of the features claimed for the carburetor is the use of a by-pass tube for providing the proper mixture at low speeds. The Kennedy is made in standard sizes, nicely finished and is held to be very economical of fuel.

Bosch Spark Plug.

Much of the efficiency of the ignition system depends upon the spark plug and the maintenance of the proper gap. When the source of current supply is a magneto the points of the plug are subject to more or less heat, varying in intensity according to the speed of the magneto. The Bosch Magneto Company, 225 West Forty-sixth street, New York City, is marketing the Bosch spark plug, which is designed to withstand severe service and although constructed for magneto work may be utilized with battery system as well. One of the qualities of the plug is the use of steatite as an insulator, a material which is forced into the shell under high pressure and one that is held to be indestructible. The method of fitting also makes for an absolutely gas tight construction. The electrodes are a high grade, durable nickel alloy, a metal especially adapted to high temperatures, and there are three of these. The electrodes of the shell terminate in a knife edge and the spark does not jump at any one particular point, but forms a ribbon of flame in its passage to the main member. Sooting is prevented as the electrodes are maintained at a high temperature, burning away any lubricant, etc., that may gather. The plugs are made in various sizes, these including 18 mm metric, .5 inch and .875 inch A. L. A. M. threads.

S. & M. Puncture Proof Tire.

The S. & M. Tire & Rubber Company, Akron, O., is manufacturing the S. & M. puncture proof tire which is, as the name implies, held to be impervious to punctures. It is of the pneumatic type and employs the same size inner tube as the conventional shoe. The side walls are made in two parts and the upper and lower extremities are provided with beads for retaining the parts to the regular rim on the felloe and the upper member. The latter is of metal and is provided with a rubber cushion tread band cured to the metal. As this is the traction member it is stated that punctures are impossible and that the fabric of the shoe is relieved from undesirable stresses occasioned by contact with stones, etc. It is also claimed that the tire will not blow-out. Large mileage and freedom from the usual tire troubles are emphasized in the S. & M. shoe, which is made in various sizes.

Morgan Garage Jack.

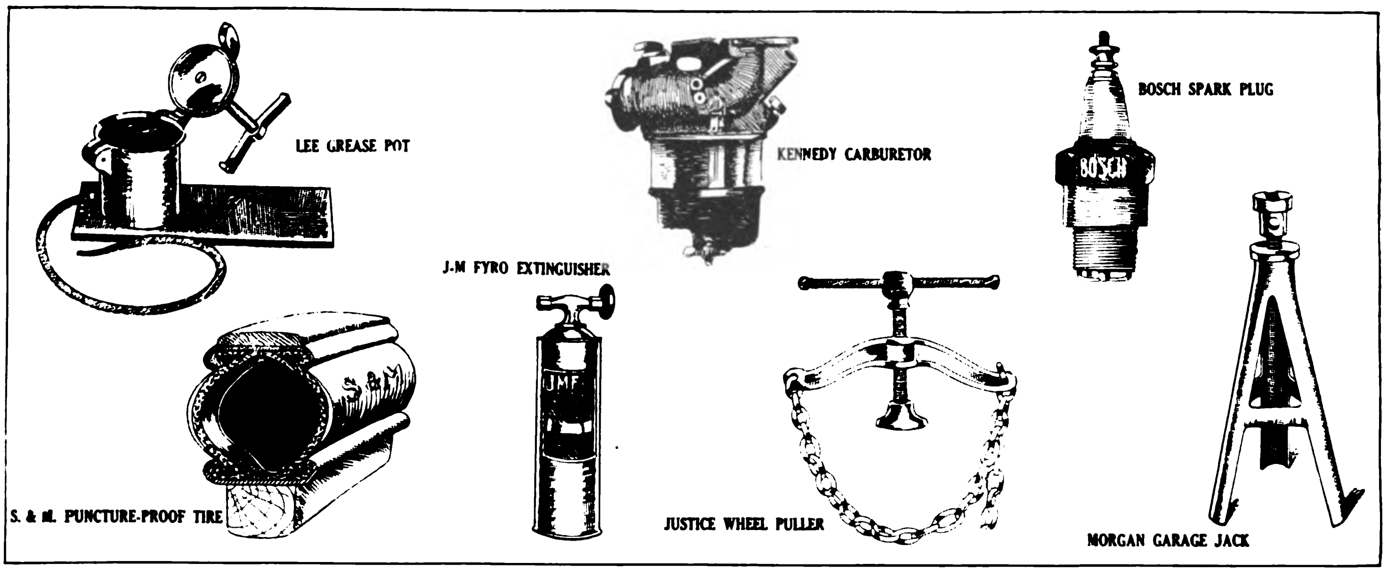
A new type of garage jack is being marketed by the Morgan Manufacturing Company, Newport, R. I., it differing from usual construction in that the base is wide and designed to prevent slipping. The base is composed of three legs and the space between them is such that the jack may be subjected to considerable side movement or swaying without tipping. The jack head is made with a recess wide enough for the chassis to fit into it and throughout the best of material is employed. The height of the jack is 20.5 inches and it has an extension of nine.

Justice Wheel Puller.

A wheel puller that is stated to have a capacity of seven tons is the Justice, manufactured by P. S. Justice & Co., 421 Chestnut street, Philadelphia. It is provided with a small round base attached to the screw member and the former may be displaced if desired by removing a set screw. Instead of arms or yokes a chain is employed and this is adjustable. It is operated in the usual manner, the chain being fitted around the hub of the wheel and the screw end applied to the axle or part. The travel of the screw member is four inches, width of yoke 16.5, diameter of base four and weight 24 pounds. The chain is 11 feet long.

J-M Fyro Extinguisher.

A new chemical fire extinguisher of the one-quart type, known as the J-M Fyro, has been brought out by the H. W. Johns-Manville Company, Madison avenue and Forty-first street, New York City. Because of its lightness and compactness it is specially adapted to be carried in the automobile or stored in the garage. It differs from the usual extinguisher in that compressed air is employed for discharging the extinguishing fluid. The latter is a liquid gas, five times as heavy as air, and on account of its weight quickly envelopes the flames, displacing the oxygen. When thrown on a fire it instantly volatilizes, forming a dense combustion arresting gas in which flames cannot live. It is claimed that one quart of the J-M Fyro liquid will expand to 4000 cubic feet of fire annihilating gas and that one quart of ordinary extinguishing fluid will make only 1000 feet. It is held to be especially effective on naphtha, oil, varnish, gasoline, calcium chloride and electrical fires. It is non-corrosive and will not injure metals, fabrics or furnishings. A feature of the Fyro is that it does not deteriorate and is not affected by differing temperatures.



Illustrating Some of the More Recent Accessories Designed for Commercial Vehicles and the Service Station.

THE A B C OF MOTOR TRUCK IGNITION.

Part X---The Mechanical Generator or Magneto---How Current Is Induced in the Windings of the Armature by Cutting the Lines of Force or Magnetism ---Permanent and Electro Magnets.

By C. P. Shattuck.

THE magneto utilized for ignition purposes in connection with the internal combustion engine is regarded as a mysterious instrument by the majority of car operators. They know that with the motor operating it supplies current for ignition, and that the supply ceases when the switch lever is moved to a certain position and the engine stops. Many who can clean and adjust the components of a magneto, such as the breaker box and distributor, and who can time the instrument, are not familiar with the principles involved. This lack of knowledge is not confined to the novice, but many who understand the practical side of the magneto cannot explain how the current is obtained.

While magnetos rarely give trouble, it is well to understand the principles involved, the relation the parts bear to one another, so that in the event of accident one will be able to cope successfully with the situation. Failure to comply with the instructions of the makers as to care and maintenance is likely to result in failure of the magneto and this usually occurs at the most inopportune time and where the services of the expert are not easily secured.

Advantages of Magnetos.

Some drivers believe that many of the so-called dual systems, batteries and a magneto, provide two independent ignition systems, either of which may be utilized. This is not true, for when the instrument is employed to interrupt the primary circuit and to distribute the high-tension current, any disarrangement of the working parts will result in inefficiency. The general terms applied to the various ignition systems are somewhat misleading, low and high-tension systems often being confounded. It is the intention of the writer to discuss the various types of magnetos, describing their construction, installation, operation and maintenance, and to present the advantages claimed for each, as well as giving instructions for correcting troubles.

The advantages of a mechanical generator over the battery and coil systems previously described are numerous. It eliminates minor troubles to which the coil and battery system is subject, provides an inexhaustible supply of current and develops electrical energy proportionately to the speed at which it is driven. Its efficiency has relegated the older form of ignition to second place and it is rare that a modern machine is not equipped with some form of a mechanical generator.

To properly understand the forces involved in the generation of electrical energy by mechanical means, a knowledge of magnetism is necessary. Magnetism and electricity are very closely allied; in fact, it is held by some authorities that the former is electricity in rotary motion. Certain substances, such as iron, steel, nickel, cobalt and their alloys show magnetic properties. The magnet was first known to the ancients in its natural form, the loadstone. They observed the difference in polarity, and also noted the repulsion existing between similar poles and the attraction between dissimilar.

Magnetic Influence.

In experimenting with the small horseshoe magnets sold as toys, it will be noted that when a small piece of iron or steel is brought within the zone of the magnetic influence it is quickly attracted to the magnet. The latter, however, has no effect upon a piece of brass, copper, tin or zinc. If the ordinary bar

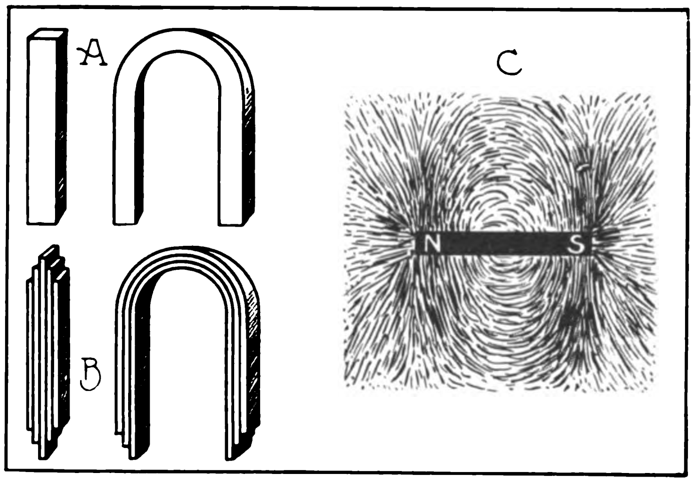


Fig. 50—Forms of Magnets and Field of Magnetic Influence: A, Simple Magnets; B, Compound; C, Illustrating Magnetic Influence of a Bar Magnet.

or horseshoe magnet be carefully examined one end will be found to be marked N, indicating the north pole. The other extremity is the south pole. If the south pole of one magnet be brought near the north pole of another a strong attraction, varying with the size and the power of the magnets, will be found present. But if this south pole be brought near a like pole of another magnet, instead of there being a strong attraction there will be noted a repulsion of like force.

From this it may be deduced that a magnet will only attract or repel a substance possessed of the same qualities; that the like poles of magnets will repel each other because of the obvious impossibility of uniting two influences flowing in opposite directions; also, the unlike poles of a magnet will, however, attract each other, because there is a continuation of the

flow of the influence of the magnet through both. This indicates that the flow of magnetism is through the magnet from the south to north and the circuit is completed by the flow of the potential or influence through the ether from the north to the south pole.

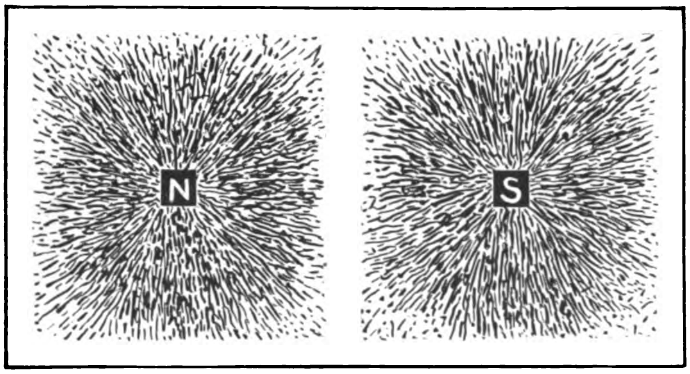

Fig. 51—Illustrating That the Magnetic Influence Is Stronger at the Poles, by Utilizing Iron Filings.

Magnets are constructed either in the shape of a straight bar or a horseshoe and these two forms are made in two types, simple and compound. The core of a spark coil is an example of a bar magnet, while the field pieces of a magneto are magnets of the horseshoe type. A compound magnet is one that is composed of a number of magnets so united that the ends of polarity are together. This form is favored because of its great efficiency and it has more magnetic strength than a simple magnet. The core of an induction coil, which is composed of a number of small pieces of iron wire, is an example of the compound magnet. Simple and compound magnets are shown at Fig. 50 A and B, respectively.

Types of Magnets.

There are two types of magnets, the electro and the permanent, although the basic principles upon which their construction and operation depend are the same. The mechanical generators employed for ignition work are known as dynamos or magnetos and are easily distinguished from each other by their construction. A dynamo has an electro-magnet which is known as a field magnet to produce the magnetic field, whereas in a magneto this field is produced by means of permanent magnets. The current is created in a dynamo by electro-magnetic production and in a magneto by magneto-electric induction. The permanent magnet is a piece of steel which has been charged with magnetism, and retains it, and is favored because it can be made more compact and lighter than the dynamo.

How Magnetism Is Produced.

Magnetism may be produced either by contact or induction. A piece of steel will retain the magnetism imparted to it for a considerable time and this is known as residual magnetism. If a piece of steel were brought within the magnetic field of a powerful magnet and allowed to remain within its influence for some time, when removed it would be found to be a magnet. This is magnetization by means of magnetic induction. If a strong electric current were made to flow through an insulated conductor wound around a piece of iron or steel it would make a magnet of it. This is magnetization by means of electro-magnetic induction, and a magnet made in this manner is termed an electro-magnet. If, however, a piece of soft or wrought iron were substituted for steel in the above cases upon removal from the magnetic influences it would retain but very little magnetism.

Lines of Force.

It has been explained that the flow of magnetism or lines of force of a magnet is from the south to the north in the body of the magnet and from the north to the south outside it. It is assumed that these lines are imaginary, but they can be made visible by a simple experiment. If a piece of cardboard sprinkled with iron filings be placed on a straight bar magnet and tapped lightly the filings will be observed to take a position similar to that at Fig. 50 C. The lines of filings should not be confounded with lines of force, for many of the lines seem to break off and do not form closed curves. If each line of filings be considered a tube of force made up of a number of lines of force, the broken lines are easily accounted for. A single line of force has not sufficient strength to move the small particle of iron, but the combined action of a number of lines or a tube of force is sufficient, and the iron is moved to a new position. Near the magnet the lines of force are more dense than at a distance, and here the lines of filings are very distinct. At a distance from the magnet the lines are more scattered and are too far apart for their combined strengths to move the particle. Therefore, while the lines of filings break off, the lines of force must be conceived to continue across the gap.

The passing of a current of electricity produces a condition of more or less strain, or whirl in the ether, and unless distorted in some way the locality of the condition is symmetrical with respect to the current. This locality is called the field of force and is considered apart from the magnet and is a magnetic field, the strength of which is measured by the number of lines of force which exist in a square centimeter of that field.

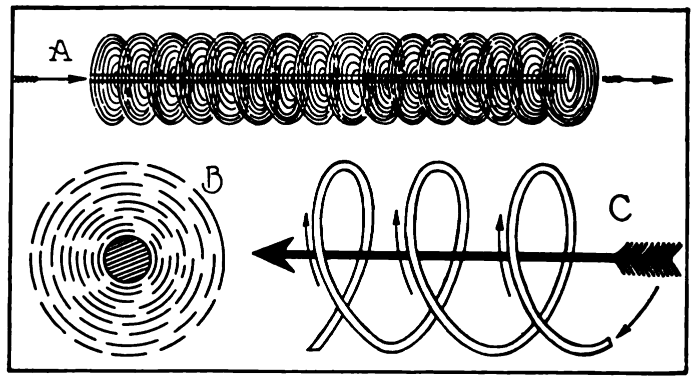

Fig. 52—Lines of Force: A, Those Surrounding an Active Conductor, the Arrows Indicating the Direction of the Current; B, End View of Same; C, Current Passing Through a Spiral Conductor.

It was discovered by Faraday that if a circuit of copper wire be caused to cut these lines of force in the magnetic field, an electric current should be set up in

the wire, and this action is termed magneto-electric induction. If the free ends of a coil of wire be connected to a galvanometer, and a magnet be thrust into the coil, a certain deflection of the needle of the galvanometer will take place, continuing only while the magnet is in motion. After inserting the magnet and upon it coming to a rest, the needle will return to its normal position. When the magnet is withdrawn the deflection of the needle will be in the opposite direction. If the magnet be inserted and withdrawn with a very quick motion, the deflection will be considerable, but will hardly be noticeable with a slow movement. The same phenomena will occur if instead of moving the magnet, it is held stationary and the coil moved, or if both of them be moved towards or from each other. The deflection of the needle indicates that a current of electricity is passing along the wire, and the experiment above described shows exactly how currents of electricity are produced in generators.

Magnetic Field.

It has been explained that a magnet is constantly surrounded by a magnetic field and that an electrical

path of least resistance, and with a given magnetizing force the intensity of the resulting magnetism is enormously increased by the presence of iron. It is for this reason that iron is utilized in the field magnets of dynamos and motors, and it is of the greatest importance that the magnetic circuit or path over which the lines of force pass shall have a large cross section and a low resistance.

Whenever a conductor of electricity is passed through the field of force surrounding a magnet, at right angles to the lines, an electromotive force is set up in it, depending upon the length of the conductor, the speed at which it moves and the intensity of the field.

Shuttle Type Armature.

The simplest form of armature is the shuttle, it consisting of a single coil of wire wound lengthwise. In practise the armature of the shuttle type of magneto is provided with two deep, longitudinal grooves, one diametrically opposite the other, so that the transverse section looks something like the letter H.

A part sectional view of a magneto is shown at Fig.

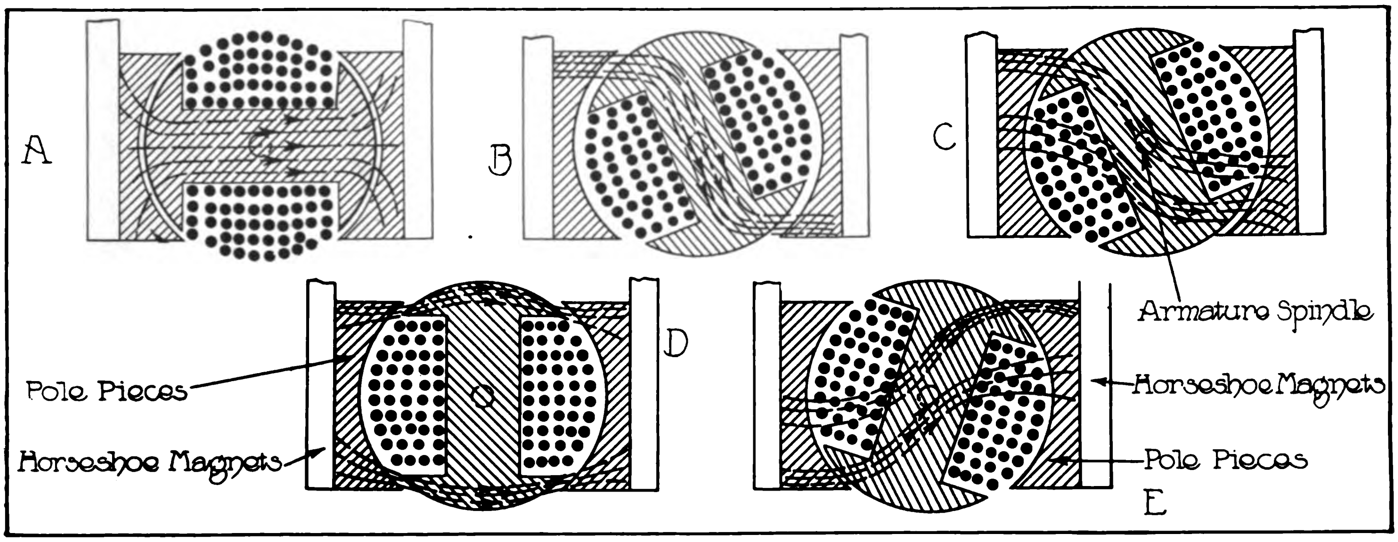

Fig. 53—Showing Changes in Magnetic Field—the Strength, Magnetic Influence and Current Induced in the Windings Vary with the Rapidity of Changes of Flow.

conductor when carrying a current is also surrounded by a field of magnetic influence. If the conductor carrying a current of electricity will induce magnetism in a bar of iron or steel, by a reversal of this process a magnetized iron or steel bar will induce a current of electricity in a conductor. It is on this principle that the modern dynamo or magneto is constructed. Electricity may be induced in a conductor by the following methods: If an electromotive force is induced in a conductor by moving it across a field of magnetic influence, or by passing a magnetic field near a conductor, electricity is said to be generated by magneto-electric induction. All mechanical generators of electric current using permanent steel magnets to produce a field of magnetic influence are of this type.

Lines of Force.

Lines of force do not pass with equal facility through all substances, most bodies offering a high resistance to them, but iron, steel and nickel are good magnetic conductors. Magnetism always follows the

53, it being of the horseshoe magnet type with a single wire winding of the armature. The magnets which produce the influence that in turn induces electrical energy in the windings or loops of wire on the armature, and which may have any even number of opposed poles, are called field magnets. The rotation of the armature in the field of magnetic influence cuts the lines of force, and the exposed ends of the magnets are called pole pieces. These are utilized to collect or concentrate the magnetic influence of the various magnets. The stationary pieces which bear against the collector or commutator, acting as terminals for the outside circuit, are called brushes. These brushes are usually of copper, or some of its alloys, because copper has a greater electrical conductivity than has any other metal.

In some cases the brushes are made of carbon, which is electroplated with copper to increase its electrical conductivity. Carbon is used as it is not so liable to cut the metal of the commutator as with a

metal to metal contact. Carbon also assists in the lubrication of the commutator and will wear and conform to any irregularities on the surface of the metal.

The coils of wire on the shuttle member are insulated and comprise a large number of turns, and the current produced depends in a great measure upon the size of the wire and the number of turns a coil. An armature with a winding of comparatively large wire will deliver a current of great amperage, but of small voltage. One wound with very fine wire will deliver a current of high voltage, but of low amperage.

Generation of the Current.

It will be seen that the crossbar of the core of the armature provides a conductor for the magnetic energy, regardless of its position, though the facility with which the influence will be transmitted depends entirely upon the position of the core. When it lies transversely between the pole pieces, as shown at Fig. 53 A, the lines of force run directly through it. Even when the armature has rotated to the position shown at B, the bulk of the lines will prefer to take the distorted path through the core instead of running directly across from pole to pole through the air.

But while the core is turning from this position to about vertical, as shown at C, the loops of wire will cut all the lines of force. The uppermost lines of force starting from the north pole will jump from the lower part of the south pole to the upper part thereof; and the lowermost lines of force entering the south pole will drop from the upper to the lower part of the north pole. As each jump and drop takes place, the lines of force are cut by the coils of the armature winding, and a current is set up therein. By the time the core has reached a vertical position as shown at D, which is attained every half revolution, the lines of force divide into two parts, one passing through the upper segment of the armature and the other through the lower.

As the armature continues its movement, the cutting begins again, but in an opposite way, both as to the lines and the coil, so that the current continues to flow in the same direction, but with decreasing intensity. Upon the core attaining a horizontal position the induced current practically ceases, but a further rotation of the armature results in the restarting of the current, which flows in an opposite direction. The currents are at their strongest or maximum at the time when the most lines of force are being cut, or about the time the core assumes its vertical positions, and it is during one of these two times that the current is generally utilized. When no lines of force are being cut, the voltage falls to zero. It will be seen that the greatest changes in the strength of the field occur as the armature passes from B to E, because during that time the magnetic field existing around the core will be destroyed and again re-established.

(To Be Continued.)

Ed. Note—The next installment will deal with the various types of low-tension magnetos.

KISSELKAR GRINDS GRAIN.

Minnesota Farmer Saves $200 a Year on Grain Bill Aside from Regular Work.

A striking illustration of the emergency value of the motor truck is shown by an experience of William Kresch, a farmer living below South St. Paul, Minn., who bought a KisselKar one-ton wagon and placed it in service Aug. 1, 1912. While pleased with the efficiency of the machine, he disliked having his investment tied up during the winter. Finally he solved this problem by jacking up the rear end, blocking the front so it would not move, taking off one tire, making a light wood block around the wheel, attaching a belt to it and ground feed, so that he could saw wood, cut fodder, etc.

Mr. Kresch ground, with the motive power of his truck, 100 sacks of feed every week. It formerly cost him six cents a sack to have this work done and he had to carry it four miles to the mill and back. This occupied the biggest part of a day. It now takes him two hours to grind his 100 sacks at a fuel expense of 60 cents, representing three gallons of gasoline and one quart of lubricating oil. Here is the way he has figured out his saving. One hundred sacks of feed at six cents a sack, $6; time saved, man and team, one-half day, $1.50; total, $7.50.

Against this he placed the cost of fuel and a helper's time at 15 cents an hour, 30 cents, a total of 90 cents. This leaves a net saving of $6.60. He has repeated this operation every week for 31 weeks, which gives him a saving for the year of $204.60. This not only wipes out the interest on his truck investment, but leaves him more than enough to take care of any amount of overhauling and repairs that could normally be necessary. Besides this he has his KisselKar in actual road service seven months of the year doing from twice to three times the work a good team of horses could do.

The Willet Engine & Truck Company has succeeded the Willet Engine & Carburetor Company and the company has removed from 60 Terrace to its new factory at 6-8 Lock street, Buffalo, N. Y. The company has begun the manufacture of the Willet chassis of two tons capacity. Other sizes will shortly be produced.

The Miner, Read & Tullock Company, New Haven, Conn., has the largest fleet of motor trucks used by any firm in that city. They are utilized in all branches of the firm's cartage and delivery system. The recent purchase of a Moeller machine, made by the New Haven Truck & Auto Works of that city, makes six of the same make now in use by the company, which was the first to purchase a locally manufactured truck in 1910. The concern is now able to handle business which heretofore was impossible owing to lack of facilities for delivery to distant points.

HINTS FOR PROPER MAINTENANCE.

ADJUSTING ROLLER BEARINGS.

Roller bearings are fitted to the front wheels of several makes of cars and while the average driver understands the adjustment of bearings of the ball type, he is prone to apply the same methods when eliminating play from the roller members. The construction of the latter, such as employed on light delivery cars, is shown at Fig. 1 and with the parts clearly marked.

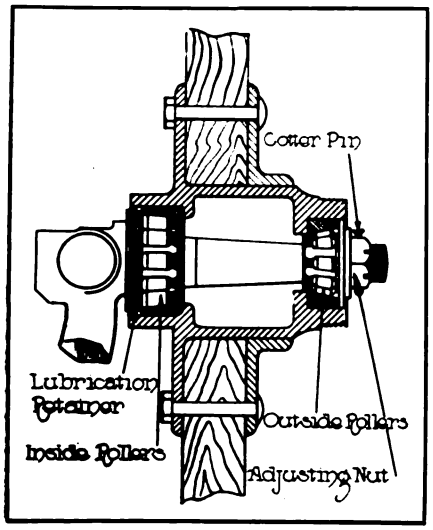

Fig. 1—Adjusting Roller Bearings.

To ascertain if the bearings require adjusting, jack up the wheels and rock them sideways, taking care not to confound wear of the spindle with that of the rollers, etc. If the wheels are loose, remove the hub cap and clean the grease from the locking nut so that the cotter pin may be removed easily. The pin should be so displaced that it may be utilized again.

To tighten the bearing, rotate the wheel, and at the same time screw down the notched adjusting not until the bearing is sufficiently snug to stop the movement of the wheel. Next slack off the nut, but only enough to allow the wheel to spin freely. Lock and replace cotter pin. It is better to have the bearing slightly loose than too tight as the rollers may be injured. Do not use so much grease in replacing the hub caps as to prevent its being screwed up home, as loss of the cap is apt to follow.

ADJUSTING TIERODS.

Alignment of the wheels is important, especially when they are shod with pneumatic tires. While the modern car is provided with adjustable tierods, there are a number of older types which have been converted into commercial vehicles and which are not equipped with means for aligning the front wheels. In the event of an accident, such as running too close to the curb, etc., the steering arm is likely to become bent, throwing the wheels out of line. If allowed to remain in this condition the tread of the shoe is destroyed because of the misalignment.

The usual practise is to bend the steering arms when the tierod is not adjustable, but this is not to be recommended. The rod may be made adjustable at slight expense and Fig. 2 illustrates methods applicable to those of the solid and tube type.

That at A is a tierod constructed of tubing which is cut near the yoke to permit of incorporating the parts B and C. The former is prepared by taking a round piece of steel and making a driving fit into the tubing, after which the piece is pinned and brazed, also threaded and a nut fitted. At C is shown the other section of the rod, and it will be noted that the inserted member is slightly larger and is tapped to take the screw bolt. With this construction it is a simple matter to lengthen or shorten the tierod by removing one yoke from the knuckle and screwing the yoke section in or out as desired, after which the lock nut is set up hard. Care should be taken to see that the yokes do not bind after locking the parts.

If the tierod be solid the plan at D may be utilized. The rod is cut and one end tapped as shown in the drawing, while the other end is turned down and threaded to fit the first part. The assembly of the rod is shown at E. It will not be necessary to cut a long thread for adjustment as a slight increase or decrease of length will be sufficient to secure the desired alignment.

STARTING ON HEAVY FUELS.

The subject of using kerosene for a motor fuel is receiving considerable attention in these days of the high price of gasoline and among the devices utilized abroad for starting a cold motor on the heavy fluid is that shown at Fig. 3. It has been in service and the maker claims that starting troubles are overcome. As will be noted by the drawing it is a valve device by means of which gasoline is fed to the intake pipe or manifold of the motor. It is screwed into the intake pipe and the source of fuel supply is a small container located on the dash or in some other convenient place.

The device includes a valve which is normally held closed by a spring, but it may be opened when desired by a cord or wire. The latter is led to the front of the car near the starting handle, and when the driver wishes to start the motor the control cord is pulled, releasing the valve and allowing a small amount of

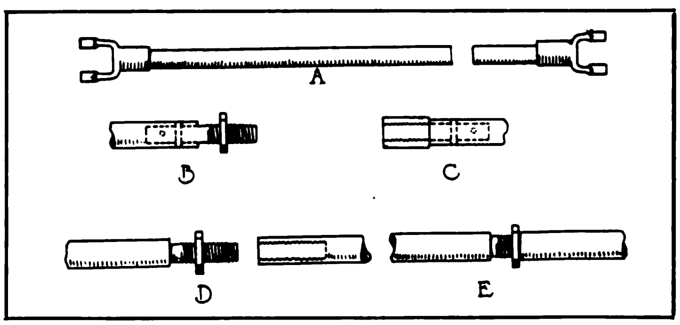

Fig. 2—Converting Tierods into Adjustable Members: A, Where the Cut Should Be Made; B and C, Method Applicable to Tierod Constructed of Tubing; D, Plan for Solid Member; E, Showing Parts Assembled and Locking Nut in Place.

gasoline to flow into the intake manifold. This is held to secure the preliminary explosions, after which the motor is supposed to operate on the combined mixture

of gasoline and kerosene supplied by the regular tank.

Details are not at hand concerning the dimensions of the openings into the intake manifold or the amount of gasoline used. The design is similar to several

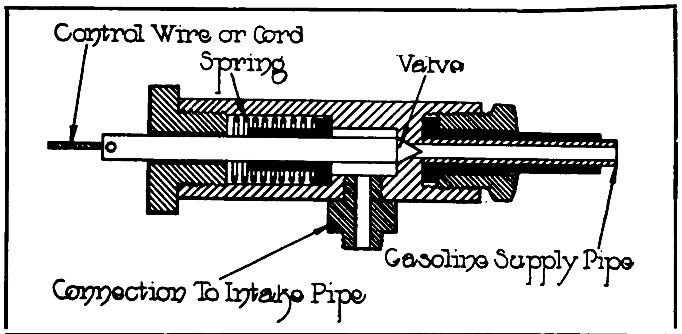

Fig. 3—Valve Device for Priming Intake Manifold with Gasoline to Secure Preliminary Explosions When a Heavy Fuel Is Employed.

priming devices made in this country for starting the motor on gasoline in cold weather. Presumably the operator acquires by experience the knowledge of how much gasoline to use to secure the preliminary explosions.

REPAIRING CRACKED CYLINDERS.

The usual practise in repairing cracked cylinders is to employ the autogeneous or welding process, although iron cements, etc., are utilized, depending upon the nature of the fracture. The Commercial Motor, an English publication, prints the following suggestion, which may be of service where a small crack is to be mended and when there is not time to send the part to be welded:

Drill and tap a small hole at each end of the crack to prevent further extension of the weakness, and screw in an iron stud. Next clean the outside and inside of the fracture very thoroughly, using a scraper and gasoline. File up some soft copper and fill the crack, heaping the filings over it. Then take a powerful blow lamp or a torch and direct the flame on the copper. By this method a fair amount of metal can be worked into the opening. After cooling, the studs are cut off flush and the copper filed smooth as shown at Fig. 4. It is said that the repair will endure indefinitely.

SOFTENING CAST IRON.

To soften cast iron for drilling, heat the part to a cherry red, and have it lie level in the fire. Then with the tongs put on a piece of brimstone, a little smaller in size than the hole to be drilled. This softens the iron entirely through. Let the piece remain in the fire until cooled.

ALUMINUM-BRONZE CASTINGS.

Discussing the making of aluminum-bronze castings, the Brass World gives some useful hints which are not generally known. The copper and aluminum, in the proportions of nine to one, should each be as pure as possible. The former should be melted first in a graphite crucible without flux, but covered with charcoal to prevent oxidation. The latter is then added and the mass well stirred with a graphite rod. Scrap metal may then be added, and the whole ingoted. When remelting, which is necessary, the heat is kept covered with charcoal, to prevent oxidation, and at proper temperature the metal is poured. It should not be allowed to soak.

Green sand molds are found to give better results than dry, although the sand itself should be dry and soft. Large risers are essential, and it is also necessary to pour quietly, and therefore, as a rule, slowly, and preferably from the bottom. The chief cause of trouble in aluminum-bronze castings is oxide, which can be reduced by preventing bubbling actions, and when formed, prevented from mixing with the body of the metal by quiet pouring. It should be poured cool with the molds laid flat, not on end.

SELF-HARDENING CUTTING TOOLS.

Some machinists complain about self-hardening steel cutting tools, stating that it is impossible to accomplish fine results in turned or planed work with them. While this is true, they are valuable for medium cuts and feeds and coarse thread cutting, machining cast iron in the shaper, planer or lathe, for turning brass castings and for different operations on cast iron parts.

FITTING WIRES OR CABLES.

In rewiring the car and when the leads pass through the battery box, floorboards, etc., it is sometimes difficult to start the wire through the opening because the diameter is less than that of the lead. The usual practise is to ream the hole larger. When wires are slightly smaller than the opening they may be started by placing the end to be inserted on a flat, hard

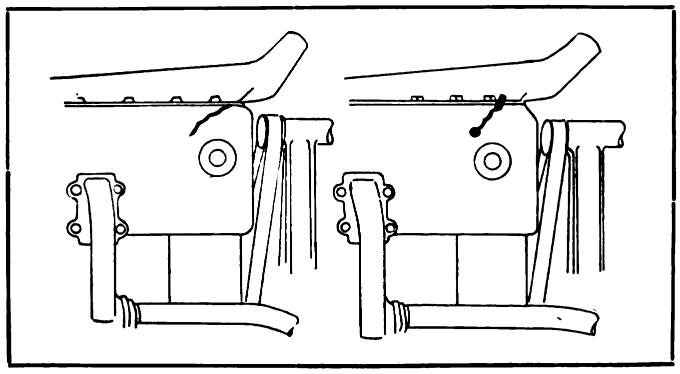

Fig. 4—Method of Repairing Cracked Cylinder by Fusing Copper Filings.

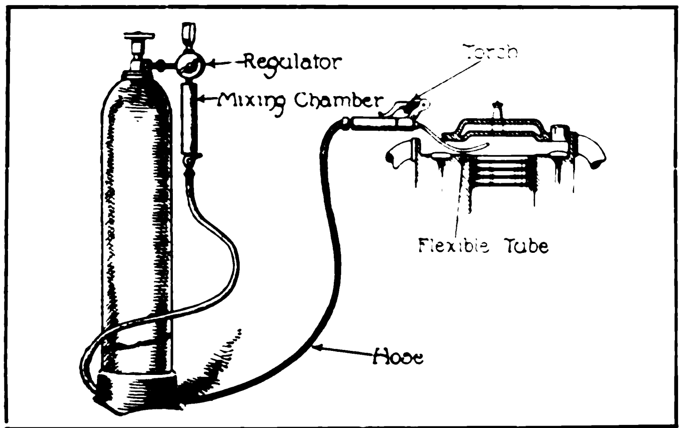
surface and rolling the insulation with another piece of hard, flat material. This will constrict the end of the insulation so that it may be readily inserted and drawn through with little effort.

GARAGE AND SERVICE STATION EQUIPMENT.

OZO, A CARBON DISSOLVENT.

Time and labor saving equipment is necessary in the repair shop catering to commercial car work because it is imperative that the repairs on the machine



Ozo Carbon Destroying Outfit, Utilization of Which Removes Deposits Without Displacing Cylinders, Etc.

be completed as quickly as possible. The loss of a few hours during the day is not desirable, especially if the car is the only one in service.

There is certain work that must be done on the gasoline vehicle periodically, such as removing the carbon from the cylinders, etc. The usual practise is to remove the cylinders, a method requiring considerable time, to say nothing of expense. Sometimes it is possible to introduce scrapers through the valve cap openings, but the more thorough method includes disassembling the motor. A carbon removing outfit has been brought out by the Ozo Company, 18 Tremont street, Boston, and with it it is possible to destroy carbon and soot deposits without displacing the cylinders, the work involving but the removal of the spark plugs or valve caps.

The Ozo outfit is shown in an accompanying illustration and the system does not include chemicals or liquids, a harmless gas being introduced into the cylinders, where it burns the carbon and without any accompanying flame. The gas is stored in a cylinder having suitable control valves, etc., and a retarding chamber or regulator is also included for reducing the pressure as desired.

The gas flows through a rubber hose to the automatic torch, attached to a flexible tube, which is inserted through the spark plug or valve cap opening, and unites with the carbon, destroying the latter entirely. Suitable controls are provided for the workman and the operation is so simple that it may be mastered in a very short time by the most inexperienced.

One of the features of the system is that it completely removes all carbon, and from places where it is not easily detached by the scraping process. The time required to complete the work varies according to the condition and number of cylinders. It is stated that the average four-cylinder motor can be cleaned in approximately 20 minutes.

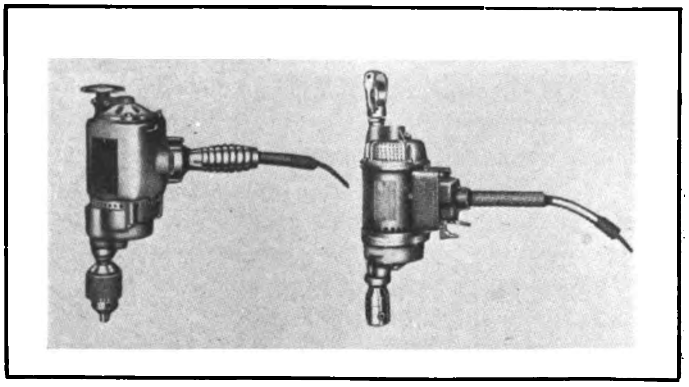
The Ozo method has been adopted by a number of garages and service stations and its principle is similar to that employed abroad.

UNIVERSAL ELECTRIC DRILLS.

Electricity as a source of power has numerous advantages and there is a growing tendency to use this form of energy for operating new machinery, such as drills, grinders, compressors, etc. In considering the equipment it is essential that it be determined whether the current is alternating or direct. The voltage, etc., also must be known. When the workman is sent to a private garage to complete some repairs and when the work requires the use of a drill for example, it will not be possible to utilize a tool operated by a direct current with an alternating source of supply.

The Chicago Pneumatic Tool Company, Chicago, is manufacturing what are termed universal electric drills capable of being operated on direct or alternating currents and two types are presented in the accompanying illustration. That shown at the left has a .25-inch capacity for metal work. It is adapted for either 110 or 220 volts and when operating at its maximum capacity the speed is 600 revolutions a minute. The equipment comprises a breast plate, chuck to take straight shank drills up to .25 inch diameter, and 10 feet of electrical conductor with an Edison connector. The drill weighs about seven pounds, is about 10 inches in height from breast plate to the end of the chuck, and consumes approximately 170 watts at full load.

That shown at the right in the drawnig is adapted for drilling holes in metal up to .5 inch and rotates at 450 revolutions a minute when operating at its maximum capacity. The equipment comprises a spade handle, No. 1 chuck, 10 feet of cord and fused connector, and two extra fuses. A breast plate is supplied in place of the spade handle when desired. The weight of the drill is 22 pounds and the shortest length from breast plate to end of the chuck is 13 inches. The approximate consumption is 400 watts.



Universal Electric Drills Operating on Direct or Alternating Current Are Constructed in Several Sizes.

It is designed for 110 or 220 volts. High grade material and workmanship are emphasized with the products of the Chicago Pneumatic Tool Company.

CORRESPONDENCE WITH THE READER.

Starting on Kerosene.

(34)—I notice considerable talk about kerosene replacing gasoline for trucks and being an owner am naturally interested. As I understand it kerosene may be used, but there is considerable trouble in starting on it. Can a motor be started cold with kerosene only as a fuel and without using heat to secure the desired vaporization? MOTOR TRUCK READER.
Boston, May 28.

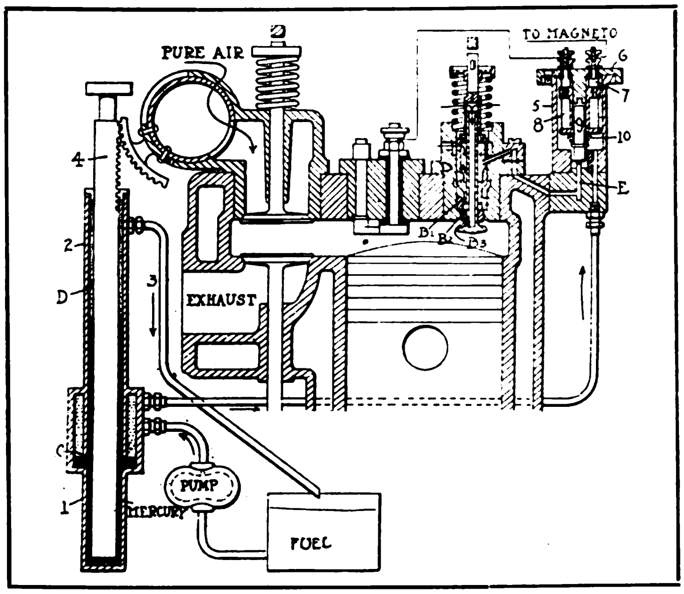


Fig. 1—General Plan of Bellem Heavy Fuel Motor, Utilizing Distributor and Magnetic Coil—The Feature of the Invention Is Pulverization of the Fuel by Injecting It into Vacuum.

Announcement was made recently of a four-cycle motor, the invention of M. Bellem, a French engineer, which is claimed to start as easily on heavy fuels, including crude oils and kerosene, as does the conventional motor utilizing gasoline. The usual carburetor or vaporizer is dispensed with, the fuel being pulverized by being injected into a vacuum formed by allowing the intake valve to open only after the piston has completed a certain portion of the suction stroke, and instead of admitting a mixture, pure air is allowed to flow through. The valve does not open until 30 degrees before lower dead centre and it closes about 30 degrees after lower dead centre. Both intakes and exhausts are mechanically operated, the latter having the usual timing.

The intake valve mechanism comprises two principal parts, a pressure regulator and a distributor. The pressure is controlled through varying the height of a column of mercury and the amount of pressure utilized does not affect the quantity of fuel. The distributor, the opening of which is independent of motor speeds, is controlled by a magnetic coil, current to which is supplied by a low-tension magneto. This electrical control renders the opening of the distributor dependent upon the weight of a needle valve and the strength of a spring.

The intake valve is of the automatic type and is in combination with the pulverizer. With the main valves closed there is considerable depression in the cylinder during the first part of the intake stroke. The automatic valve shown at Fig. 2 B is opened by the suction of the piston. The charge of fuel is brought up the valve under pressure. At the same time a certain amount of air and the liquid are brought in from A and B, through the openings B 1 and B 2 respectively. Pure air is then drawn through the stem of the valve. which is hollow, and holes B 3, completely pulverizing the fuel.

The delivery of the fuel is accomplished by the pressure regulator and the distributor. The former is supplied from the tank by a pump. It comprises a metal vessel 1, containing mercury, and welded to it, a metal tube the lower end of which is level with the top of the mercury. Located in the tube is a plunger 4, capable of being raised or lowered in any convenient manner, and according to its position this varies the height of the column of mercury D in the tube 2. The pressure of the fuel in the chamber C is regulated by the column of mercury.

The overflow or excess of fuel passes through the mercury column and down an overflow pipe 3 to the tank. The feed pipe has a capacity slightly greater than that of the motor under full power. The quantity of fuel flowing through the return pipe is negligible and no mercury is carried through with the fuel. The plunger is connected to the air valve, and a single operation, controlled either by a governor or by hand, determines the pressure of the fuel to the distributor and the amount of air admitted to the motor.

A feed pipe connects the pressure chamber with the distributor at the right of the automatic valve. As the pressure is variable the distributor is not called upon to regulate the quantity of fuel as its opening must be constant and independent of motor speed. The magnetic control is shown at Fig. 2 A. It comprises a soft iron core 5, with a cover 6, to which is secured the coil 8, by means of insulated terminals 7. In the centre of the coil is a needle valve 9, which is held on its seat by a coil spring 10. At the instant of breaking contact on a low-tension magneto the needle valve

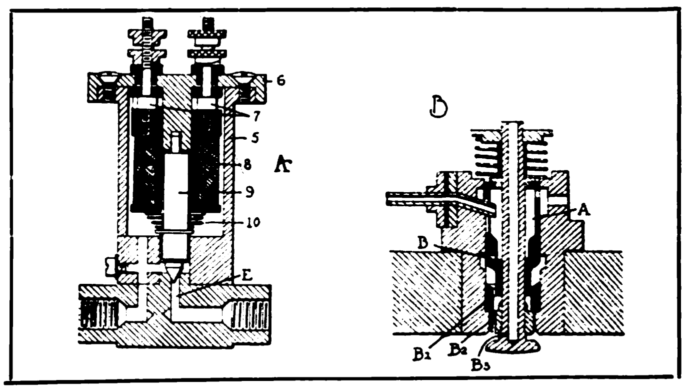

Fig. 2—Details of the Bellem Motor: A, Magnetic Control, Current to Which Is Supplied by Low-Tension Magneto; B, Automatic Valve and Ports for Fuel and Air.

is raised from its seat and the fuel under pressure in the feed pipe enters through E to the pulverizer. The opening of the valve is instantaneous and depends on the weight of the needle valve and tension of spring.

(Continued from Page 429.)

er of an electric pleasure vehicle, anyway, has so many ideas offered to him in regard to promised service that by the time he has completed his purchase he has service, guarantee and maintenance mixed up in one portion, with the firm conviction in his mind that all these things together mean—his car can be operated without cost to him, except the garage charges. I am firmly convinced that it is necessary to adopt a standard service that can be offered to the prospective buyer as a standard service, so that he may know exactly what he may expect after he puts his car in operation.

I am pleased to say, unofficially, that the Electric Automobile Manufacturers' Association have this very question of service up for discussion and hope within the next 30 days to offer to their members for adoption a standard service which will be, with possibly a few exceptions, as follows:

1. Free inspection once a month of car at garage or service station, provided it is sent to the station at the time specified by seller. 2. Charge will be made for this service unless the car is delivered at station on day agreed upon. 3. No charge will be made for examining wiring, motor, controller, brakes, steering, running gear, or an examination of the battery to determine the time for washing or its general condition, as to whether it is being properly flushed and cared for. Nor will a charge be made for oiling the entire car which, however, does not include repacking of bearings or gears in grease. 4. If inspection develops any needed repairs, due to natural wear, accidents or other causes, the owner will be notified of same and an estimate of cost for doing the work furnished. 5. This service in no way eliminates the responsibility of the garage in which the car is kept.

If this standard service is adopted by the E. A. M. A.—and I believe it will be—it will establish a precedent for the honest salesman's use and it will eventually result in an actual profit to the honest agent, for the reason that as his business grows and more cars come in for inspection each month, repairs that can legitimately be charged for will be developed more and more, until the service proposition, which is now a misnomer and a nightmare, will actually become a source of profit to the seller, as well as a source of comfort to the buyer—to say nothing of the advantage it would mean to the average salesman. There are other points regarding the service question that cannot be touched upon in this short address.

The selling proposition—It is a self-evident fact that after the quality, style and probable demands of the public are considered, as well as the selling policy of the manufacturer, the actual placing of the car after all is in the hands of the salesman. The question of the electric vehicle salesman at the present time is to my mind one that should be carefully discussed, particularly in the retail end of the electric pleasure vehicle business, and there are some things connected with the electric vehicle salesman that could, at least, be changed for the real benefit of the salesman and the employer.

I believe that this condition—so far as the salesman is concerned—could be improved through an association as powerful as the Electric Vehicle Association, particularly if the assistance of the local organizations could be obtained, and I am sure it could be.

Competition in the electric vehicle business is getting keener each year and it has by no means reached its climax, and I am of the opinion that it is absolutely necessary to correct some of the existing evils in this line of business, in order to offset the loss of profit which is brought about by the very keen competition that exists at the present time.

I believe that the Electric Vehicle Association should appoint committees to take up these questions and see that something is done to improve existing conditions.

The discussion that followed this paper concluded the evening session.

The third and concluding session was begun the following morning at 10, the first paper being on "Advertising the Electric Vehicle from the Manufacturers' Standpoint," by F. Nelson Carle, advertising manager for the General Vehicle Company, Long Island City, N. Y., who spoke as follows:

Advertising the Electric Vehicle.

From an advertising standpoint the electric truck is a much more prosaic proposition than the electric passenger car. The point of contact is very different. Each has its own field and its own appeal. The manufacturer who can enlist the interest of women readers in his product has a tremendous advantage. At the same time we are making remarkable progress in both phases of electric vehicle advertising. It should be remembered that advertising parallels the progress of an industry. It need not necessarily be crude in its early stages, but it will lack the proper objective point just as much as introductory selling does. And before I try to tell you what electric vehicle advertising has accomplished, I ought to show you how such advertising is often influenced, if not restricted, by the selling policy.

Assuming that a good electric truck, in particular, has been developed or acquired by a group of able men, there are two ways in which they can reach the goal of national distribution. One is to start with large capital and tie it up in, say, 15 branch offices until such time as the volume of business will support such a huge selling organization, and the other is to start with moderate capital and a nucleus of, say, three branch offices and expand as any old line of business on a sure foundation would. We have left the first mentioned plan largely to our gasoline truck competitors, many of whom have had for years a splendid national selling organization for their passenger cars and are marketing their trucks through the same channels. Some of us feel that the truck would better be divorced from the passenger car in selling, but perhaps that is a matter of opinion.

The motor truck owes much to the automobile, yet it has inherited some things from it which are giving the industry a lot of trouble just now, and one of these is unsound expansion. So we may congratulate ourselves I think that not only have electric truck makers taken the lead in sound design, sane speed and other fundamentals of long lived construction, but they are leaders also in sound selling. They recognize that adaptability insures operating efficiency. That permanent satisfaction for the buyer is what really counts in building for the future. Working along these lines takes patience and courage. To be consistent the manufacturer must at first follow the lines of least resistance in selling and perhaps sell the bulk of his product in given centres or to certain lines of trade. He must sell each machine at a profit and sell it only where adaptability will insure high operating efficiency. If he patiently persists in this, his back will not be broken by the free service and repair station, and his reorder business will offset the greater expense of introductory selling in new territory. Little by little he will be able to add branch offices and other units to his distributing system and grow as all business should grow—along normal and healthy lines. Not all electric vehicle manufacturers look at the selling problem in the same light, but all realize that while we may be in the automobile business, we must make money if we are to stay in the truck end of it. How to make the turnover and expand at the same time is the problem. So in view of the foregoing you can see how electric truck advertising is being influenced by selling conditions peculiar to the electric. Over these conditions we have practically no control, though they are improving from year to year. Probably very few of you realize how hard some of us are working to bring our advertising into harmony with the selling plan so that there will be no lost motion, and every dollar will count. This makes the advertising man chafe at some of the restrictions, but it is good training for him.

To reinforce intensive selling with advertising directed to the whole country not only seems expensive to most manufacturers but, viewed in the light of immediate results, wasteful as well. Perhaps this is why much of electric truck advertising is done in the newspapers of branch office cities to the neglect of other mediums. Each manufacturer does things a little differently. I have found that such advertising to be most effective must be localized. No two cities offer quite the same selling problem, and what is true of sales should be true of advertising. Educational copy written on broad lines is helpful in any city, but intensive copy adapted primarily for New York will not fit in Chicago, Boston or other cities. It will not fit because of the variation in three important factors: 1, road or traffic conditions; 2, status of the horse delivery contractor; 3, status of the electric truck. If the electric has a good foothold in a given city and is on the whole well spoken of, it is much easier to produce results from a given expenditure than it would be in a city where these conditions are reversed.

There has been a marked improvement in such newspaper advertising, and when we take our copy away from the sporting page with its golf news and prize fights and put it on the news pages there will be more. Let those who favor the automobile style of advertising for trucks consider what we are trying to accomplish with a small allowance a truck on a limited annual output, and they may deal with us more kindly. Criticisms are welcome and appreciated so long as they are constructive.

Trade paper advertising has been condemned by many, but not as a whole, I think, by those who have studied the matter carefully. There are many trades which will always be relatively non-productive for electric trucks, but there are others which have already invested heavily in them. Such trades respond to advertising when it is directed to them in the language of that trade. The mistake is too often made of running the same piece of copy in a dozen different trade papers, and that procedure deserves no results. Magazine advertising is bringing both the electric truck and electric passenger car more and more before prospective buyers, and the importance of the advertising being done by the Electric Vehicle Association of America is tremendous, especially at this stage of the industry. Such advertising has cumulative as well as educational value, and I only wish we individual manufacturers could follow the lead of the Electric Vehicle Association with page copy to a greater extent than we do. I have briefly indicated in general, why we are not in just the best position to invest largely in national advertising at the present time. It would be splendid if each large manufacturer at least could appropriate $100,000 a year for this purpose, but only a very large volume of business would warrant at this time such a long term investment. Of course we are getting there by degrees.

Central station advertising in the interest of the electric vehicle is increasing from year to year, and even though the central station doesn't spend its own money to increase electric vehicle sales, it can do a lot for the manufacturer by aiding him in the study of local conditions. For that matter, if we were to carry this spirit of co-operation to its logical end, every one interested in the success of the electric vehicle could aid in a very practical way in increasing its sales. If I were the advertising manager of an electric vehicle concern in Chicago, for example, trying to help my company open up New England territory, I would certainly consider it of prime importance to know something of local conditions. I wonder how many of you gentlemen have contributed your knowledge of local conditions to the general fund of data on New England as a mar-

ket for the electric vehicle? If you saw that my advertising failed to take into account conditions peculiar to Boston, Providence, or Worcester, would you, if you were a well posted battery man for example, try to enlighten our local representative in some way, or would you let him waste good money in trying to accomplish the impossible under the circumstances? If there is only so much available for educational work on the part of all the electric vehicle interest, doesn't all money so wasted indirectly hurt your end of the business?

About a year ago I had occasion to write a series of newspaper advertisements for a certain town, in which I hammered the shortcomings of the horse with unusual fervor. The advertising fell flat. Recently I spent two days in that city and got what I thought was a pretty good line on conditions. Just as I was about to get on the train a friend of mine asked if I knew that a certain department store was going to put in its own delivery system again. A few rapid fire questions on my part developed the fact that fully 70 per cent. of the general trucking and department store deliveries were really controlled by three contractors. The wagons bore the names of the respective stores and had fooled me nicely. Here I had been advertising to merchants of that city about the high cost of their horses when some of them had not owned a horse for five years. That is but one example of what not only we advertising men, but salesmen, are up against all over the country, and the central station executive or the local battery or tire man who will co-operate with the electric vehicle manufacturer in posting him on local conditions paves the way for intelligent local advertising. Many a salesman has wasted time and energy in endeavoring to develop electric vehicle sales in new territory with practically no results, simply because information which he should have had was not available to make his work easier. I do not say that it is not every salesman's first duty to post himself on conditions in his territory, but if some individual sincerely interested in the success of the electric of either type were to give the new man on the ground, perhaps in one hour, what it would take the newcomer six months to acquire for himself, surely here is co-operation which will ultimately pay big dividends. In this connection, no advertising man can possibly hit the nail on the head each time without help from the salesman and the central station on the ground. The branch offices of his company are relatively few in comparison with the countless local problems to be considered, so here is where the electrical interests everywhere can help the whole electric vehicle movement.

Electric truck advertising has already accomplished much more than we give it credit for. It has been believable and has inspired confidence in the storage battery vehicle. It has won men over to a point where they will at least concede the superiority of the electric in its field. Now we must educate them to see the size of that field—to see the tremendous relative volume of city trucking and intercity or other long haul trucking. Impress upon the prospective buyer the importance of adaptability as a factor in operating efficiency. Keep before him the value of simplicity in construction and operation as a factor in the labor problems. Many electric truck advantages are founded on economic laws, and when a man understands this he gets away from the all-automobile idea and into the realm of transportation machinery, and that is what we are selling. Our advertisers are not mud slingers, and that counts much in the public mind. Merchants and manufacturers are getting the impression that we are trying to build as we go instead of trying to cover the country with our product in 12 months, and that appeals to them, since it is in harmony with sound business principles. These impressions gaining in volume from day to day stamp the electric, not as something marketed in haste only to be distanced by the 1914 model, but a machine backed by a principle which is right, and so must endure.

I look forward to the day when this industry will draw to it the keenest advertising minds of the day. Men who make their work a religion rather than a pastime or means to an end. In the selling end we are slowly but surely being favored with clean cut men who are a splendid asset. They come not so much to get in on the ground floor as the industry takes a boom as because they sincerely believe in the electric principle. And we need men of this stamp in the industry, even more than we need additional capital. If we can bring our advertising up to where it will create that spirit of spontaneous confidence, not only in our product, but in our way of doing business, we shall not lack boosters. And certainly the world smiles at the man whose heart is in his work.

Advertising Electric Vehicles from Central Station Viewpoint.

The concluding paper of the convention was "Advertising the Electric Vehicle, from a Central Station Standpoint," by E. J. W. Proffitt of the Narragansett Electric Light Company, Providence, R. I. He took the position of the third in the triangle of buyer, seller and advertising man, emphasized the value of advertisement, praised the publicity campaign of the Electric Vehicle Association of America, and credited the co-operative endeavors of the different interests with much of the success thus far met with. The quality and efficiency of the electric vehicle is known and with perfected machines he believed the problems of distribution and service would be satisfactorily solved.

He included advertising with distribution. He was of the opinion that the campaign of the Electric Vehicle Association of America should have been sectional instead of national because, in his mind, the greatest field for the electric vehicle was in the eastern part of the country, and maintained that had this campaign been in part in newspapers the central stations would have been able to co-operate in it. He did not favor the electric vehicle manufacturers placing their advertising appropriations in the hands of the Electric Vehicle Association to be handled by that body, but suggested that the central stations and manufacturers supplement the publicity of the association along predetermined lines, and that this work should not be left undecided before the next campaign is inaugurated. He believed the value of supplemental advertising could not be over-estimated.

In central station advertising one of the most important factors is service, and he believed it distinctly inadvisable for the central station to advertise the electric vehicle extensively until such service shall have been provided, or else it is prepared at its own expense to supply this service. The central station cannot afford to assume the whole burden because of the limited income, and he suggested that while the central station was logically the interest to supply this service the manufacturer should allow the central station a certain sum for each vehicle sold in the territory of a given station. The manufacturer could then advertise this service, which would be a valuable factor in selling, he could furnish a guarantee that the central station could make good, eliminating all questions and doubts, and making it possible for the central station to aggressively push the business for its own and the manufacturer's gain.

Discussion of Mr. Carle's and Mr. Proffitt's papers was followed by discussion in which Mr. Bartlett described the advertising campaign carried on by the pleasure car dealers of Philadelphia.

Adjournment was taken after the papers had been referred to the executive committee to formulate plans and policies, and there had been an understanding that the central stations would send out with statements and communications to their customers such literature as might be prepared by the association, setting forth the advantages, utility and economy of electric pleasure cars and service wagons.

The delegates went to the Relay house, Bass Point, Nahant, where a ball game was engaged in by teams representing the electric vehicle manufacturers and the central station interests, but a group visited the works of the General Electric Company at West Lynn, arriving in season to see the vehicle team win by an estimated score of 24 to 23. Then came the dinner at the Relay house in the evening, with a series of one-minute speeches, at which Mr. Kimball officiated as toastmaster and time keeper.

The delegates attending the convention were the following:

F. P. Allen, Whitten-Gilmore Company, Boston; L. R. Abel, American Storage Battery Company, Boston; W. C. Anderson, Anderson Electric Car Company, Detroit, Mich.; A. H. Abbott, General Electric Company, Boston; D. E. Bent, Edison Storage Battery Company, Boston; W. H. Atkins, Edison Electric Illuminating Company, Boston; E. B. Burleigh, General Electric Company, Boston; H. W. Briggs, Edison Electric Illuminating Company, Boston; H. E. Crane, Crane Auto Garage Company, Providence, R. I.; R. Bennett, Anderson Electric Car Company, Boston; O. F. Barstow, General Electric Company, Boston; J. C. Bartlett, Woods Electric Garage Company, Philadelphia, Penn.; E. J. Bartlett, Baker Motor Vehicle Company, Cleveland, O.; J. S. Brown, Lowell Electric Company, Lowell, Mass.; E. W. M. Bailey, S. R. Bailey & Co., Amesbury, Mass.; D. W. Beaman, New Bedford Gas & Edison Electric Company, New Bedford, Mass.; William G. Bee, Edison Storage Battery Company, Orange, N. J.; J. L. Brown, Anderson Electric Car Company, Boston; K. L. Curtis, Anderson Manufacturing Company, Boston; J. W. Cook, Electric Storage Battery Company, Boston; F. Nelson Carle, General Vehicle Company, New York City; J. C. Codman, S. R. Bailey & Co., Amesbury, Mass.; C. F. Clark, Electric Vehicle Company, Worcester, Mass.; W. B. Conant, Electric Review, Brookline, Mass.; C. H. Clark, Holtzer-Cabot Electric Company, Brookline, Mass.; A. E. Carpenter, Atlantic Vehicle Company, Boston; E. Carpenter, Oak Bluffs, Mass.; T. I. Donahue, Edison Electric Illuminating Company, Boston; E. R. Davenport, Narragansett Electric Light Company, Providence, R. I.; Edmund Davis, Philadelphia Storage Battery Company, Philadelphia, Penn.; O. G. Draper, Electric Motor Car Club of Boston; L. L. Edgar, Edison Electric Illuminating Company, Boston; W. H. Francis, Edison Electric Illuminating Company, Boston; D. C. Fenner, International Motor Company, New York City; C. L. Edgar, Edison Electric Illuminating Company, Boston; M. A. Frank, Motz Tire & Rubber Company, Boston; J. J. Flynn, Standard Electric Car Company, Jackson, Mich.; Bruce Faxon, Wagner Manufacturing Company, Boston; W. J. Fitch, General Electric Company, Lynn, Mass.; E. E. Greenwood, Edison Electric Illuminating Company, Boston; Henry Goodman, Buffalo Electric Vehicle Company, Buffalo, N. Y.; J. E. Gray, Narragansett Electric Light Company, Providence, R. I.; R. C. Gregg, Philadelphia Storage Battery Company, Philadelphia, Penn.; R. S. Hale, Edison Electric Illuminating Company, Boston; W. E. Towne, Narragansett Electric Light Company, Providence, R. I.; A. H. Alcott, Narragansett Electric Light Company, Providence, R. I.; Day Baker, General Vehicle Company, Boston; B. A. Gookin, Narragansett Electric Light Company, Providence, R. I.; P. A. Gallagher, Jr., Narragansett Electric Light Company, Providence, R. I.; W. H. Angevine, Narragansett Electric Light Company, Providence, R. I.; E. D. Osgood, Buffalo Electric Company, Buffalo, N. Y.; F. B. Carter, General Vehicle Company, Boston; C. H. Hatch, Edison Electric Illuminating Company, Boston; C. J. Hatch, Edison Electric Illuminating Company, Boston; J. A. Hunnewell, Lowell Electric Light Company, Lowell, Mass.; C. E. Holmes, Cambridge Electric Light Company, Cambridge, Mass.; R. L. Holmes, Narragansett Electric Light Company, Providence, R. I.; M. M. Hammond, Anderson Electric Car Company, Boston; W. B. Jones, Webster Electric Company, Boston; E. C. Kimball, Edison Electric Illuminating Company, Boston; S. J. Kniv, Wetmore-Savage Company, Boston; H. L. Knowlton, Electrical World, Boston; F. M. Redman, General Electric Company, Boston; John Kelly, Edison Storage Battery Company, New York City; Alexander Michaud, Salem Electric Light Company, Salem, Mass.; J. McDonald, Cambridge Electric Light Company, Cambridge, Mass.; O. E. Mitchell, Narragansett Electric Light Company, Providence, R. I.; E. H. Macready, Narragansett Electric Light Company, Providence, R. I.; F. S. Marr, Philadelphia Storage Battery Company, Philadelphia, Penn.; E. S. Mansfield, Edison Electric Illuminating Company, Boston; J. C. Henderson, Woods Motor Vehicle Company, Chicago, Ill.; Converse D. Marsh, New York City; C. L. May, Boston; Ira Miller, Westfield, Mass.; J. J. Buckley, Edison Electric Illuminating Company, Boston; L. D. Gibbs, Edison Electric Illuminating Company, Boston; H. W. Moses, Edison Electric Illuminating Company, Boston; A. E. Josselyn, Edison Electric Illuminating Company, Boston; R. C. Norton, Baker Motor Vehicle Company, Cleveland, O.; F. R. Newell, Worcester Electric Light Company, Worcester, Mass.; A. F. Neale, Waverley Company, Boston; D. B. Neth, Connecticut Company, Waterbury, Conn.; A. F. Nelson, Edison Electric Illuminating Company of Brockton, Brockton, Mass.; E. N. Norris, Edison Electric Illuminating Company, Boston; C. E. Page, Malden & Melrose Gas Light Company, Malden, Mass.; Edward J. W. Proffitt, Narragansett Electric Light Company, Providence, R. I.; F. N. Phelps, Baker Motor Vehicle Company, Boston; L. P. Perry, Narragansett Electric Light Company, Providence, R. I.; T. M. Pike, National Carbon Company, Cleveland, O.; A. D. Putman, Worcester Electric Vehicle Company, Worcester, Mass.; C. C. Pilsbury, Westinghouse Electric & Manufacturing Company, Boston; J. C. Patterson, Anderson Electric Company, Needham, Mass.; E. Phaneuf, Electric Machine & Instrument Company, Boston; C. A. Perry, D. C. Tiffany Company, Boston; N. Rommelfanger, Boston; F. S. Rogers, Waverley Company, New York City; R. W. Rollins, Worcester Electric Light Company, Worcester, Mass.; A. H. Robbins, Electric Light & Power Company of Arlington and Rockland, North Arlington, Mass.; Harvey Robinson, secretary of the Electric Vehicle Association of America, New York City; E. A. Shanahan, General Electric Company, Lynn, Mass.; S. F. Smith, Salem Electric Light Company, Salem, Mass.; Frank J. Stone, Electric Storage Battery Company, Boston; C. D. Stanford, Atlantic Vehicle Company, Boston; Ralph Sanger, Atlantic Vehicle Company, New York City; F. E. Sawyer, Salem Electric Light Company, Salem, Mass.; H. H. Skinner, Narragansett Electric Light Company, Providence, R. I.; F. H. Smith, Worcester Electric Light Company, Worcester, Mass.; J. W. Sanger, Atlantic Vehicle Company, Boston; J. E. Spike, Cambridge Electric Light Company, Cambridge, Mass.; H. E. Taylor, Lansden Company of New England, Boston; F. T. Taylor, Cutler-Hammer Manufacturing Company, Boston; Willis M. Thayer, Hartford Electric Light Company, Hartford, Conn.; T. J. Toohey, Narragansett Electric Light Company, Providence, R. I.; H. F. Thomson, Massachusetts Institute of Technology, Boston; H. H. Van Stranzer, Westinghouse Electric & Manufacturing Company, Boston; L. Vredenburgh, Edison Electric Illuminating Company, Boston; J. E. Whiting, Edison Electric Illuminating Company, Boston; C. A. White, Edison Electric Illuminating Company, Boston; E. E. Wallace, General Vehicle Company, Boston; J. West, Jenney Company, Boston; Adamson Battery Company, Boston; A. Weatherby, Anderson Electric Car Company, Boston; E. J. Wood, Narragansett Electric Light Company, Providence, R. I.; L. R. Wallis, Edison Electric Illuminating Company, Boston; P. E. Whiting, S. R. Bailey & Co., Amesbury, Mass.; Harrison W. Wagner, Consolidated Gas Electric Light & Power Company, Baltimore, Md.; George D. Baxter, Haverhill Electric Company, Haverhill, Mass.; F. R. Ball, Haverhill Electric Company, Haverhill, Mass.; R. C. Batting, Batting Coal Company, Malden, Mass.; Henry Clark, Winchester Suburban Gas Company, Winchester, Mass.; G. W. Ellis, Boston; P. A. Gallagher, Narragansett Electric Light Company, Providence, R. I.; F. S. Gassaway, Willard Storage Battery Company, New York City; P. H. Johnson, Cutler-Hammer Manufacturing Company, Boston; H. Kingsley, Salem Electric Light Company, Salem, Mass.; R. C. Newcomb, Blackstone Valley Gas & Electric Company, Woonsocket, R. I.; F. T. Sanderson, North Abington Electric Light and Gas Company, North Abington, Mass.; W. H. Snow, New Bedford Edison Company, New Bedford, Mass.; Thomas Toomey, Narragansett Electric Light Company, Providence, R. I.; F. W. Trickey, B. F. Goodrich Company, Boston.

LEAVES INTERNATIONAL MOTOR.

Well Known Writer on Motor Truck Subjects Retires as Advertising and Publicity Manager.

Rollin W. Hutchinson, Jr., advertising manager of the International Motor Company, New York City, maker of Mack, Saurer and Hewitt trucks, has resigned his position, which took effect June 1. Mr. Hutchinson has had charge of the advertising and publicity of the International company and its predecessor, the Saurer Motor Company, since their establishment, and has acquired a unique and comprehensive knowledge of motor truck subjects and the attitude of business interests toward them.

Being a graduate engineer and a student of mechanical sciences, his view of the motor industry has been especially intelligent and comprehensive and his articles on trucking subjects and traffic economies have given him a national reputation as a writer and student of these topics. As a producer of genuinely educational publicity he has been prolific and distinguished.

QUICK CLIMBING WITH KELLY.

California Owner Hauls Load of Provisions to Lick Observatory Over Mt. Hamilton Road.

Louis Normandin of the Normandin-Campen Company of San Jose, Cal., recently made a run with a oneton Kelly truck, made by the Kelly-Springfield Motor Truck Company, Springfield, O., loaded to capacity with fruit, provisions, etc., from the centre of the city to Lick Observatory on Mt. Hamilton in 2:45:00.

The run was made over the regular Mt. Hamilton road, which was found to be in good condition, but considering the steep grades the time made by the truck was exceptional. The return trip was made in 2:05:00 and no adjustments were found to be necessary during the journey.

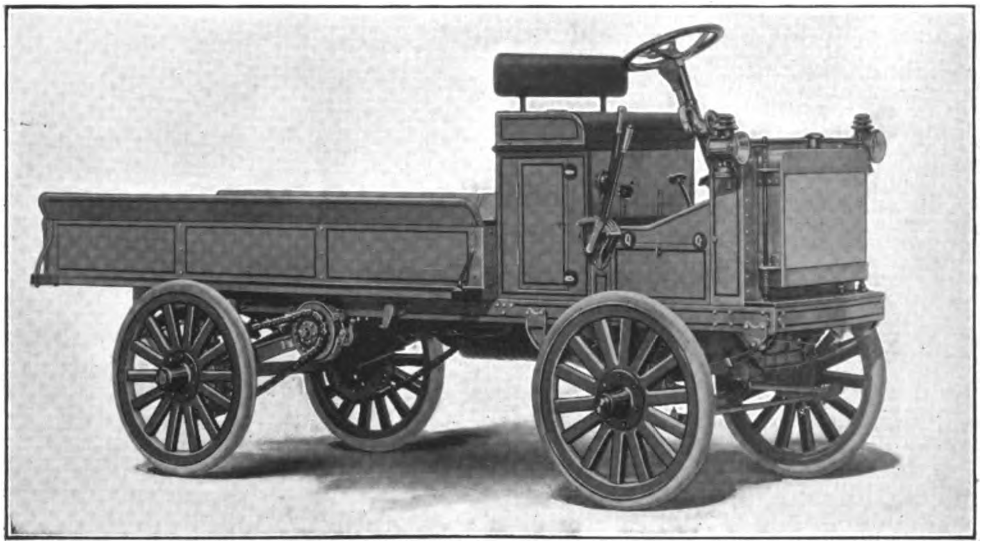
SANFORD 3000-POUND MODEL L WAGON.

THE model L delivery wagon built by the Sanford Motor Truck Company, Syracuse, N. Y., has 3000 pounds capacity and it is a standardized production. It was developed to meet a demand for a machine of larger capacity than the model K, a 2000-pound wagon, and aside from proportions it is identical with the smaller. The Sanford wagons are the development from nine years' experience, and the maker maintains that they embody every desirable quality that makes for strength, endurance, efficiency and minimum maintenance and operating expense.

The power plant is a unit, the motor, clutch and transmission gearset being assembled together. The motor is a four-cycle, four-cylinder, water-cooled, L head type with the cylinders cast in pairs. The engine has a bore of four inches and stroke of 4.5 inches, this giving 25.6 horsepower by the S. A. E. rating. The valves are at the left side of the motor and the stems, springs, tappets and guides are protected by cover plates that may be easily removed. The crankcase is a barrel type with a base inclined forward so as to insure sufficient lubrication while the machine may be ascending a grade. A large extension of the rear of the case houses the flywheel and clutch, and to this is bolted the housing of the transmission gearset. There is a long side plate at the left of the engine case and two plates at the right, which may be removed for work or examination of the motor shafts or bearings. Two other plates afford access to the clutch and gearset cases. The timing gears are housed by a forward extension of the crankcase and a cover plate. The gears drive the camshaft and an outside shaft that drives the centrifugal water pump and the magneto, the latter being carried on a bracket.

The lubrication is by a combination force feed and splash system, the oil being drawn from a two gallons capacity reservoir in the base of the crankcase by a pump driven off the camshaft, and being filtered before it is circulated. The motor is cooled by a circulation of water through a large radiator and the water jackets by a centrifugal pump, and radiation is promoted by a four-bladed fan mounted on an adjustable bracket on the forward cylinder unit, driven by a flat belt from a pulley on the crankshaft extension. The carburetor is an automatic float feed type that supplies a uniform mixture at all engine speeds. The motor is governed by a governor driven by the outside shaft and connected with the fuel intake that is contained in a case that can be sealed so that it cannot be changed by the driver. The ignition is by a high-tension magneto.

The clutch is a multiple disc construction, which is made with 16 crucible steel plates, hardened, tempered and ground, which is oiled by the same system that lubricates the engine. The transmission gearset is a selective type, having three forward speeds and reverse, the shafts being of large diameter and mounted on annular ball bearings, and the gears are wide faced and of general proportions. An interlocking device prevents more than one set of gears meshing at one time. The transmission shaft is a special work, being drop forged from special analysis steel, hardened, heat and ground. The power plant is carried in the frame supported at three points. The drive is to the jackshaft by shaft, and then by chains to the rear wheel hubs.



The Sanford Model L Delivery Wagon, Capacity 1.5 Tons, the Latest Product of the Sanford Motor Truck Company, Syracuse, N. Y.

The frame is a steel channel section five inches width and of liberal depth, with heavy and well reinforced cross members, the front member being shaped to form a bumper to protect the radiator. The frame is supported by semi-elliptic springs 2.5 inches width forward and a platform construction at the rear. The forward axle is an I section three inches by 1.875 inches, the rear axle is a heavy rectangular section, both of which are fitted with roller bearings. The wheels are 36 inches diameter with 3.5-inch tires forward and four-inch tires rear. The wheelbase is 118 inches. The drive is right side, with right hand speed changing and emergency brake levers, and with spark and throttle levers on the steering wheel. The clutch and service brake are controlled by pedals. The service brake shoes operate with contracting bands on drums on the jackshaft and the emergency brake shoes are external contracting on drums on the rear wheels. Both brakes are fitted with equalizers. The chassis are fitted with standard type bodies and with the usual lamp, horn and tool equipment.

ELECTRIC POWER WAGONS AT PITTSBURG.

THE following letter has been received by MOTOR TRUCK, and the facts set forth are of material interest to all who are concerned in power wagon transportation. The writer has had opportunity to observe and investigate conditions and his conclusions are based upon fact:

Editor, Motor Truck:—

"Where Are the Electric Vehicles?" is the title of an article published in a recent issue of a magazine devoted to power wagons, and the query in the caption should seemingly be accompanied by a statement of fact, but even casual examination will demonstrate many errors, though probably written from what was assumed to be reasonably correct information. For instance, Boston is credited with 130 electric vehicles, when there were 279 in that city Jan. 1, 1913. Pittsburg is given but one or two machines of this type, the source of information is stated to be the Allegheny County Light Company, and the reason for so few a number is claimed to be "the hills." These statements are wrong. The Allegheny County Light Company gave merely the number of its own machines, but not the total in use in Pittsburg. There are 19 vehicles used commercially and seven industrial trucks in operation in the city.

That electric vehicles are not more numerous in Pittsburg is not because of the hills, for actual demonstration has proven capacity, but is due to the fact that those now in use are from seven to 10 years old, are very crude as compared with machines now produced, and these are seldom, if ever, maintained so as to obtain anything like a reasonable work. That Pittsburg is a "poor town" for electrics may be met by the statement that the people are living in a very dim past so far as these machines are concerned. The vehicles are old and in every respect cannot be compared with those regarded as standard productions. Yet, McCreery & Co.'s seven-year-old wagon is frequently driven 45 miles on a single charge, and one of the officials of the company is authority for the statement that this machine is operated at a saving of 40 per cent. as compared with any other type of vehicle. The five-ton Vehicle Equipment truck of the Bindley Hardware Company has covered 28 miles to a charge over the streets of Pittsburg, up and down the hills as they are met, and this machine is nearly 10 years old.

Considering the work done with the electrics, and making comparison with any other type of vehicle, it will be admitted that the results are surprising. Here is an example: A large Pittsburg concern installed two 3.5-ton trucks seven or eight years ago. The engineer of the plant has charge of these when in the garage. This engineer and his company today condemn all electrics, but here are the facts: The engineer states that the battery of each truck weighed 850 pounds and was rated at 10 horsepower and that the motor was rated at 10 horsepower. No battery has a rating of weight or horsepower, but to accept this and taking a 850-pound battery as the basis—the lead battery of a 1000-pound delivery wagon today weighs from 1100 to 1300 pounds and the lead battery of a 3.5-ton truck 2700 to 2900 pounds, but this truck was designed to carry 7000 pounds, and the battery was ridiculously small. It could not have adequate power. The motor was 10 horsepower. In proportion to the size of the battery a two horsepower motor would have been very large, but this machine was equipped with a battery less than a third of the size now used and with a motor more than twice the size now installed in 3.5-ton trucks. The result was that the motor wasted current taken from the small battery, the energy was rapidly exhausted and there was no power available for any length of time. A 10 horsepower motor would be suited for an eight-ton truck, but one of 3.5 or four horsepower would be sufficient for a machine such as was used, for the motor can be given a temporary overload of 300 per cent. if necessary to climb a hill, go through sand or pass over a rough road. One of the economies of an electric machine is the small power needed for good roads and the possibility of increasing this from a four to a 16 horsepower in the event of need.

With this strangely proportioned equipment, the small battery and the big motor, this truck was driven from 10 to 12 miles on a battery charge, though no one knows whether the battery was properly charged. Should one take a 3.5-ton gasoline chassis and install a motor suited for a 1000-pound wagon and a driving system built for an eight-ton truck, and endeavor to carry 3.5 tons of load, it is probable the machine would hardly move the load. But the electric truck carried its freights surprising distances considering the construction.

About three years ago a wholesale liquor dealer bought a 1.5-ton electric wagon that had been used for four years. In less than a year the machine was condemned. As a matter of fact the battery was charged at the shop of the owner morning, noon and night, whenever it was not driven, sometimes an hour, sometimes more and sometimes less; the ampere rate of charging was unknown and the battery was never given a full charge, possibly not a half charge, and certainly not an over-charge, as should be given each alternate week. With a battery charged in this manner no machine could be driven on hills or on the level, but the owner attributed the seeming lack of capacity to the wagon and did not consider his own ignorance or the absence of management.

In practically every instance where electric vehicles have not given satisfaction in Pittsburg the cause can probably be traced as have those stated. But it is certain enough that the machine built by a reputable manufacturer will climb hills, carry its load and give excellent mileage, but where there is a shortcoming it is the limited mileage and the slower speed, so far as Pittsburg is concerned, for the topographical conditions are unusual. Pittsburg may be likened to a human hand with the four fingers and thumb stretched wide apart, these being taken as the principal thoroughfares extending from a base from west to east, with ridges having grades of from 40 to 90 per cent. between these main ways of traffic. Save a few downtown cross streets there are no highways connecting these five highways. While an air line between two points may be a mile or less, it is necessary for delivery to be made around the hills, often necessitating a drive of from four to eight miles. This condition makes it necessary to do a greater proportion of haulage to do a given work than is required in almost any other community. For this reason speed regarded as essential in Pittsburg and the absence of cross streets is a decided handicap to the slower moving electric, yet there are numerous instances where circuits can be made instead of returning over streets once traversed. The electric vehicle can be utilized to good advantage in Pittsburg if the owner and driver would study its possibilities.

Very truly yours,

WILLIAM KIENER.

Pittsburg, Penn., May 26.

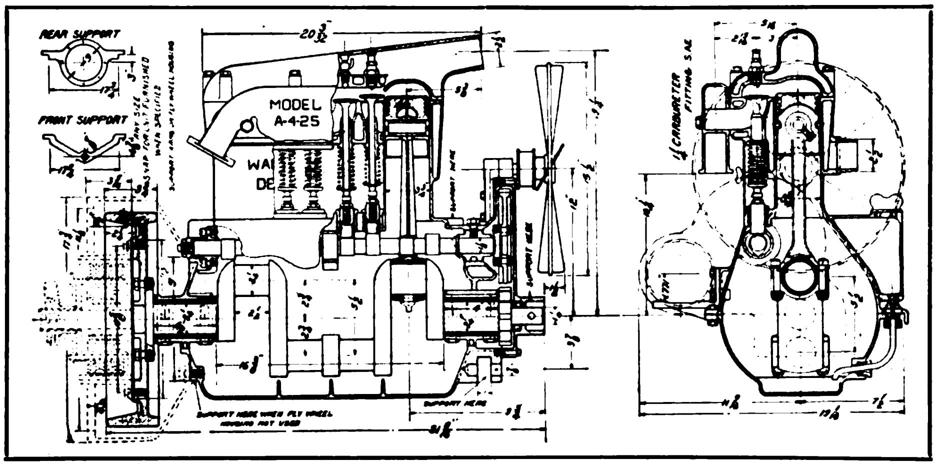
The Rand-Morrison Manufacturing Company has purchased 10 acres of land at East Boston, Mass., on the Boston & Albany railroad, and will erect there a plate shop, erection shop, machine shop, power plant, pattern shop, foundries and general offices. Contracts have been made with McClintic-Marshall Construction Company of Pittsburg, Penn., for the machine and erection shops, to Levering & Garrigues Company of Dunnellon, N. J., for the plate shop, to the New England Foundation Company for the foundations, and to the Shaw Electric Company for the electric cranes. The shops will be completed by July 1, it is expected. They will be equipped with four 10-ton and one 25-ton electric cranes. The company makes a specialty of coal handling machinery and steam and electric hoists and contracts to erect and equip the largest docks for the handling of coal in all parts of the world. The works when completed will employ 1000 men. There are now orders on hand for at least one year's production. The officers of the company are: President, Gov. Eugene N. Foss, Boston, Mass.; vice president and general manager, Willard S. Martin, Cambridge, Mass.; treasurer, John G. Morrison, Cambridge, Mass.; and the directors include those named and William J. Hoyt, Manchester, N. H.; Frank P. Carpenter, Manchester, N. H.; Burton L. Gale, Melrose, Mass., and Arthur P. French, Boston, Mass.

By the use of a Kelly one-ton delivery wagon the Coca Cola Bottling Company, Rome, Ga., has, according to Manager F. S. Biron, saved $50 weekly. This economy is in the hotel bills for drivers and the stable bills for horses, as well as having the use of the machine when it is needed. Before the wagon was purchased two wagons and teams were used, and two drivers, but now one man handles the machine. The other bills are unnecessary because every haul can be made in less than a day, but with the horses it was necessary to pay hotel and stable expenses for two or three nights each week.

WARNER-DETROIT MOTORS.

Company Formed to Build Power Plants for Passenger and Freight Vehicles.

The Warner-Detroit Motor Works is the name of a company organized at Detroit, Mich., to manufacture engines for passenger and freight vehicles, from designs by H. L. Warner. The first motor has been produced and is known as model A-4-25. It is an L head type and is unusual in that it has a bore of 3.1875 inches and stroke of 5.5 inches, the bore to stroke ratio being 1:1.72. The motor is rated at 16.2 by the S. A. E. horsepower formula, but it is claimed by the maker that it will develop nearly twice that power. The motor is a block type with the cylinders and upper half of the crankcase integral, and the oil reservoir is formed at the left side of the upper part of the case. The entire head of the motor is removable, permitting easy access to the cylinders and valves. The water spaces are large and the circulating fluid is carried to the bottoms of the expansion chambers.



Sectional Drawings Showing the Construction of the Warner-Detroit Model A-4-25 Motor.

The cylinders and pistons are of semi-steel and this affords a very light, but strong construction. The upper half of the engine case carries the crankshaft and camshaft bearings. The crankshaft is a two-bearing type, being 2.25 inches diameter. The front main bearing is four inches length, and the rear main bearing 4.5 inches length. The pistons are each fitted with four rings, three above and one at the ends of the wristpin, and the wristpins oscillate in the piston bosses. The camshaft is 1.125 inches diameter. The magneto shaft is one inch diameter. The connecting rods are channel section, of unusual length and very light. The small ends are clamped by a bolt, and the big end bearings are retained by two clamping bolts.

The timing gears are .875-inch face. The cams of the valve mechanism are one-inch face. The valves are with ports 1.5 inches, and the valve heads are cast iron electrically welded to nickel steel stems. The tappet rods are fitted with adjusting screws and lock nuts and operate within guides carried in the engine case. The valve springs are long and well tempered. The valve mechanism is protected by plates retained by wing nuts that cover the pockets in which the valve rods operate.

The lubrication is a vacuum-gravity system, the oil flowing from a reservoir in the upper half of the crankcase through a tube to the base of the engine case. So long as the lower end of the tube is below the surface of the oil no lubricant will flow, but when the level falls air will be admitted to the tube and the flow will continue until the level is reached and the tube end submerged. In the base of the engine are low baffle plates, and there are drains through these so that the level of the oil may be equalized. The motor is cooled by the thermo-syphon system, and radiation is promoted by a large fan driven by a belt from a pulley on an extension of the magneto shaft. The water inlet and outlet are made to take 2.5-inch hose for radiator connections. The flywheel is machined for the installation of a cone or a multiple disc clutch, and the case is adapted for fitting any bell housing of a transmission gearset. Brackets allow the fitting of any magneto or lighting and starting installation. The motor is built for hard work, it is short, compact, and all the parts are well made. The crankshaft and camshaft are 3.5 per cent. nickel steel, carefully heat treated.

The company proposes to produce about Aug. 1 a six-cylinder motor, with the cylinders cast en bloc, which will have the general characteristics of the engine that has been outlined. The company will also produce a sliding gear transmission having three forward speeds and reverse, with multiple disc clutch and levers for use with either type of motor it will build. H. L. Warner, founder of the Warner Gear Company and the Muncie Gear Works of Muncie, Ind., who recently disposed of his interests in the Warner Gear Company, is general manager of the company. With him is associated as general superintendent W. H. Lonsdale, for several years superintendent of the Knox Automobile Company and a mechanical engineer of long experience, and W. H. Downes, formerly of the Chas. A. Strellinger Company, as secretary.

E. W. Lyle, for a considerable length of time with the Alden Sampson department of the United States Motor Company, has been engaged by the Adams Bros. Company, Findlay, O., as superintendent.

The business of the Victor Motor Truck Company, Buffalo, N. Y., is now being conducted by the receiver, Marc W. Comstock, and it is expected that the affairs of the concern will be adjusted satisfactorily.

Alfred Pick & Co., Chicago, Ill., has purchased 10 Bessemer delivery wagons of one ton capacity.

WHOLESALE GROCERY DELIVERY BY TRUCK.

Louisville Concern Makes Experiment with a Kelly Demonstrator and Finds Decided Economy, Though Machine Is Not Worked to Its Greatest Capacity.

By G. D. Crain, Jr.

THE cost of delivery is relatively more with the small equipment than with the larger, and this is a very potent reason why there should be maximum economy sought by those who have services that may be included in the former classification. It is entirely practical for the concern of large resources to make a change in its distributing methods and to invest a considerable amount, while with those doing a smaller volume of business it may be essential to have the entire capital available. Where distribution is confined to a definite section the cost is less than were it a larger area, and it often follows that a delivery may be in a community where the distances are considerable and the cost of haulage is correspondingly high.

The owner of the business that requires several wagons may be convinced of the possibilities with motor vehicles and yet not willing to make a change because of the uncertainty of results in the conditions in which the work is done. It is a fact that the limitations of animal haulage are not always realized until after experience with motor wagons, and the failure to develop the most certain and logical economies is often due to an unwillingness to make changes that seem radical, but are abundantly justified.

Three-Ton Kelly Truck in the Service of Kentucky Grocery Company, Louisville, Ky.

An illustration of the value of the single truck is the experience of the Kentucky Grocery Company, Louisville, Ky., which has a wholesale establishment and customers throughout the city and its suburbs that must be served by road vehicles and business elsewhere that can be supplied by freight and express. Within the radius of Louisville and the suburban districts delivery has been at all times a problem, for the hauls vary from five miles in one direction to 10 in another, and with streets and highways not always good, especially in the winter and spring, and with extreme heat in summer, animals are necessarily hard worked.

While it is a fact that humanitarian considerations would have prompted using animals with care so far as loads and distances were concerned, yet it is certain that economy demanded that the delivery should be made with as great speed as possible and the loads be as heavy as could be hauled. One of the longest hauls made in the city delivery is to South Louisville, a prosperous and thickly populated community, where a full load was delivered with horses once a week. From the warehouse to the customer the distance is approximately 12 miles, the total distance for the animals to travel being close to 25 miles.

A delivery made to this suburb required a two-horse team and wagon and with a start made early in the morning practically all of the day was necessary, for the outward trip could not be driven fast, and the horses were not forced returning. Officers of the company say that in hot weather it was not unusual for the team making this delivery to be until 11 in the evening on the road. The increase of the business meant more frequent deliveries or heavier loads, and it was realized that the patronage of the customers depended upon their receiving their orders as quickly as possible. After carefully studying the conditions and the limitations of horses, and estimating the possibilities for business promotion, the officers of the company investigated the merits of motor trucks.

Power wagons were used in Louisville by a number of companies in the haulage of furniture, whiskey, beer, structural steel, plumbing fixtures and supplies, and differing merchandise, but after careful observation it was by no means a certainty that a truck would give the company the results desired, for it was believed that one machine ought to do all of the long hauls and a considerable part of the city deliveries. Though the officers of the company were willing to work out the problem and judge from actual work accomplished they were not confident that the motor truck would be as productive as was hoped for, and they concluded that they would gain their experience as cheaply as was practical. So instead of buying a new machine they purchased a Kelly truck that had

been used for nearly three years by Killgore & Stilz, the Louisville agent for that make of vehicle. Worked as a demonstrator the truck had not been spared, but it had been well maintained and was in excellent condition when it was transferred to the grocery concern.

The company had used three two-horse wagons to the time the truck was acquired, and believing that the machine would take the place of two of these, four horses and two wagons were disposed of. The two drivers of these wagons were made the crew of the truck after they had been given such instruction as in the judgment of the agent for the maker was necessary to qualify them to operate it. The first thought might have been the saving of one man's wages, but the main object was expediting the loading and unloading of the machine, that the standing or idle time might be minimized. The problem as seen by the owners was economizing in wages or in the usefulness of the machine, and as they wanted the work without any question they decided to get the fullest use of the truck.

Just what the company had with which to begin its experimental work may be interesting. There are those who will maintain that a truck that had been used three years is not a wise investment, but the machine had been well kept up mechanically, and in the service of the agent it had not been neglected. Experiment with tires had been begun by the agent, and when the truck was sold it had three Hartford and one Kelly-Springfield block tires, the latter being on a rear wheel. These were 36 by four-inch shoes. The price paid for the truck was $1820.

Beginning July 1, 1912, when the machine was transferred, the company kept a very accurate record of the work accomplished and the expense of operating, and this has been supervised by Robert E. Adams, the president, who says that his purpose was to learn precisely the cost as compared with animal service and to compare the relative work and determine efficiency from a cost as well as a service viewpoint. In this account the truck was placed against the two two-horse wagons that it replaced.

The company had carried four horses in its inventory at $150 each, though their cost was greater than this and they could have been sold for more than that figure. The total value was $600 for the animals and the wagons were estimated at $200 each and the two sets of double harness at $35 a set, making the total valuation $1070. The truck cost $750 more than this amount and at interest of six per cent. this made a monthly charge of $3.75 additional against the truck.

At the expiration of 31 weeks, or practically the end of the winter, the cost of the truck was found to be as follows:

Wages of two men	$620.00
Fuel and oil	169.73
Repairs, including new lamps, etc	316.55
Total	$1106.28

This was an average of $158.04 a month for seven months.

The cost of the wagons for a similar period was as follows:

Wages of two men	$620.00
Horse board at $17 a head a month	476.00
Horse shoeing at $11.20 a month	78.40
Wagon repairs at $5 a month each	70.00
Total	$1244.40

This gave an average of $177.77 a month.

This showed $137.12 total in favor of the truck for the period stated, or an average of $19.75 a month, and deducting from this the interest charge of $3.75 a month this made the net saving $15.98. But as a matter of fact this does not represent the full value of the machine, for with it more work is done than with the horse wagons and the possibilities with it are by no means reached.

In the matter of depreciation no charge has been made against either the truck or the horse equipment, and while it may be maintained that the repair bills for the machine were larger than might have been expected with a new vehicle, it is also certain that there would be relatively a considerable item charged against this account for the animals and the wagons. The wagon repairs are averaged at $5 a month for each, which is really very low when it is understood that bills for $90 for repairing the remaining wagon were recently received by the company. Another item not included is the loss through sickness or incapacity of horses. To illustrate: Another concern in the same business lost a horse that fell dead on returning from a hard haul with a heavy suburban load. Another horse developed a corn and for six months was idle in a stable at an expense of $16 a month, and was later pastured at $5 a month for three months, after which it was sold for $25. The veterinary's bill was $75.

In February one of the Hartford tires was replaced at a cost of $125, but the new shoe is guaranteed for 10,000 miles, and when the mile cost is considered this item is comparatively small. The mileage of the truck has not been fully kept because the odometer was not operative a part of one month from the necessity for repairing a gear connection, but as no record was made of the horse wagon this datum would not be useful for comparison were it complete.

The main result is this: That the company has found that a truck can be operated at least as cheaply as two two-horse wagons, without reducing the number of men employed, and not only is the work more quickly and better done, but there is a large reserve that is always available. Not only this, there is the satisfaction from a more expeditious delivery, which is a large factor in retaining patronage. From the viewpoint of the company the experiment has demonstrated the efficiency of the truck beyond all question.

The Haney Fire Fighting Apparatus Company, Stockton, Cal., through its president, Edward H. Haney, and its general manager, Edward Olds, announces its proposed removal to Tampa, Fla., where it will manufacture fire fighting apparatus and motor trucks. The company, which is incorporated for $2,000,000, is said to have purchased 31 acres of land southwest of Tampa and has contracted to build a plant at a cost of $50,000.

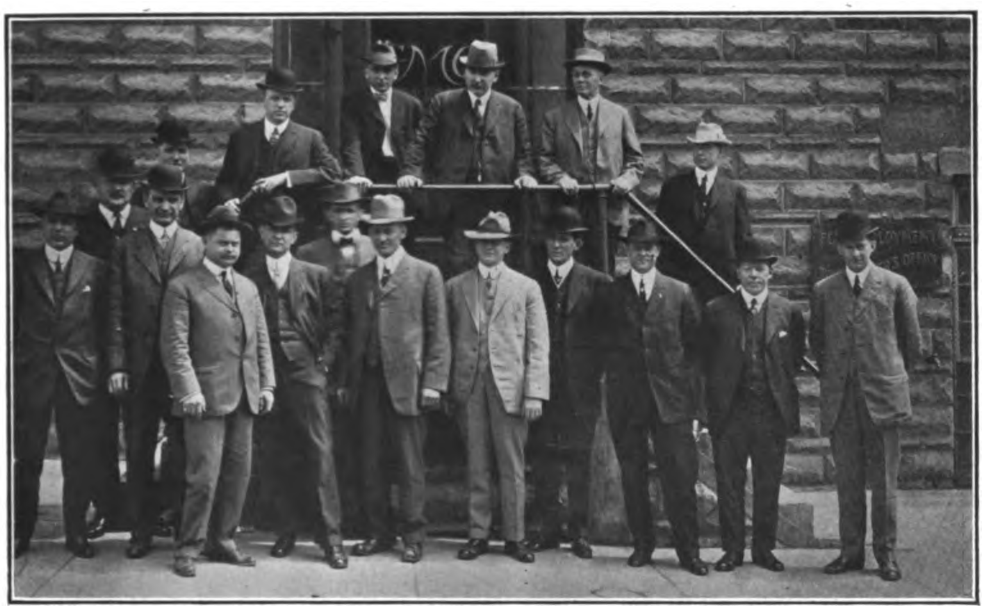
G. M. C. SALES CONVENTION.

First Annual Gathering of District Managers and Executives at Pontiac, Mich.

The first annual convention of the district managers and executives of the General Motors Truck Company took place at the factory of the company at Pontiac, Mich., May 27-29, inclusive, and was attended by something more than a score of men. The purpose of the gathering was to consider the marketing conditions as seen in different sections of the country, and to adapt the methods and policies so far as was possible for the purpose of promoting business and service.

Among those in attendance were Charles D. Warren, New York City; J. L. Morris, Boston, Mass.; J. C. Ayers, Detroit, Mich.; E. J. Kilborn, Chicago, Ill.; Estel Scott, Kansas City, Mo.; N. A. Neil, Omaha, Neb. The first day of the convention the company was addressed by President Charles W. Nash of the General Motors Truck Company, and at the other sessions the gathering was in charge of Vice President W. L. Day and Sales Manager W. L. Chilcoot.

The convention was productive of material benefit, according to the officials of the company, in that the exchange of views and experience of the different managers more closely harmonized the organization and brought about a thorough understanding of the demands of the public, as well as harmonizing endeavors along well defined lines. Not only this, but it brought about the adoption of plans that will extend and improve the service of the company.



The District Managers and Executives of the General Motors Truck Company in Convention at Pontiac, Mich., May 27-29.

MACK MERGES COMPANIES.

The Webb, Maccarr and Lansden Concerns Consolidate at Allentown, Penn.

The Webb and Maccarr companies of Allentown, Penn., and the Lansden Company of Newark, N. J., have been consolidated and the Lansden factory will be removed to Allentown. In fact a considerable part of the machinery has already been moved and as soon as it is installed in the Allentown plant activities will be resumed.

The control of the Webb company was acquired by John M. Mack, who was the active spirit in the Mack Bros. Motor Car Company, and who founded that concern at Allentown. When the Mack company was merged with the Saurer and the Hewitt companies as the International Motor Company, Mr. Mack was prominent in the affairs of that organization. He retired last year and purchased control of the Webb Motor Fire Apparatus Company of St. Louis, Mo., removed it to Allentown and changed the name to the Webb company.

Late in the autumn the Maccarr company was organized to build delivery wagons by Mr. Mack, who had associated with him a number of friends. The first machines were shown at the New York and Boston shows. A short time ago W. L. Case, who had been general manager of the Lansden Company for something more than a year, retired. Mr. Mack had acquired a large interest in the Lansden company and the announcement of the merger and the removal of the Lansden plant is no surprise to those who are familiar with the recent changes. No announcement has yet been made as to the name of the concern, or whether the companies will have nominally separate existence or will be operated as divisions.

The Webb company manufactures fire apparatus of every type, both gasoline and electric equipment, having the right to use the Couple-Gear gasoline-electric and the electric battery construction and the Couple-Gear wheels for the electric wagons and trucks. The Maccarr company has produced two types of delivery wagon, having 1500 and 2000 pounds capacity. The Lansden company builds electric wagons and trucks from 1000 pounds to five tons capacities. The supposition is that the products of each concern will be continued without change and that the selling organization will be considerably extended.

The advertising manager of the motor truck division of the American Locomotive Company, L. A. Van Patten, retired from that position June 1 and has associated himself with Harry S. Haupt, Inc., the New York agent for Lozier cars.

VEHICLE RESEARCH DATA.

Bulletin No. 3 of the Transportation Investigation of the M. I. T.

Vehicle Research Bulletin No. 3 has been issued by the electrical engineering department of the Massachusetts Institute of Technology, Boston, Mass., and it has been prepared by Prof. Harold Pender and H. F. Thomson under the title of "Observations on Horse and Motor Trucking." This compilation is necessarily condensed and it is not possible to give the conditions of service, but many facts are presented that will be found factors in practically every problem that may be considered. For instance, there is the bearing of the human element, the mental attitude of the driver, the conditions of trucking, the importance of standing time, the short and long hauls, the routing of the wagons, the mileage factor, the load factor and the delivery of freight; but there are other conditions that are not shown, such as the topography of the locality, the wages paid, the cost of fuel and power, the overhead expense, the character of administration, the influence of traffic and traffic regulations, varying restrictions, the forms of streets and highways traversed, and other items that have material bearing.

The cities in which data have been obtained include New York, Chicago, Philadelphia, St. Louis, Boston, Detroit, Washington and others of less population. The information has been widely varying in character, some of it being from systems that are comprehensive and accurate, and in other instances simple methods have been devised for obtaining some of the more important detail, it being understood that the records would be supplied the investigators as they were accumulated. In every instance, however, the facts desired were given in confidence, and with the understanding that they were not to be used for advertising purposes. For these reasons the identities of the sources of information have not been disclosed.

With the data available the study has been directed toward analyses of the work accomplished with the different vehicles, but the information is by no means sufficient to justify conclusions, especially with reference to animal wagons. The observation of registers of work, which was carried on with the vehicles of nine Boston firms, covered 63 different machines and wagons, ranging from one to three-horse teams and from 700 to 10,000 pounds capacity motor trucks. The observation continued from two to eight months' work with each. In all something more than 100,000 observations were studied and these will be tabulated and arranged graphically, but are not yet available. The bulletin gives the details of five estimates which are based upon the cost data published in bulletin No. 2. These are for wagons of the following capacities, which are regarded as being adapted for the service specified: 1000 pounds rated capacity, suburban parcel delivery; 1000 pounds rated capacity, city parcel delivery; 4000 pounds rated capacity, furniture delivery; 7000 pounds rated capacity, draft beer delivery; 10,000 pounds rated capacity, coal delivery.

Taking the suburban parcel delivery the estimated annual expense for the electric is $2455; the gasoline vehicle, $2810; the horse wagon (two-thirds extra horse), $1854. The daily cost is $8.60, $10.40 and $6.50 in the order named; the mileage cost is 23 cents, 27 cents and 23 cents, and the delivery cost 6.7 cents, 7.5 cents and 8.5 cents respectively.

The estimate for city parcel delivery is: Annual expense, electric, $2365; gasoline, $2735; horse wagon (two-thirds extra horse), $1812. The daily cost is $8.30, $10.10 and $6.04 in the order named; the mileage cost is 25 cents, 30 cents and 27 cents, and the delivery cost 4.2 cents, five cents and 4.5 cents respectively.

The estimate for the furniture delivery shows the following: Annual expense, electric, $2794; gasoline, $3366; two-horse wagon (one extra horse), $2457. The daily cost is $9.75, $12.50 and $8.60 in the order named; the mileage cost is 31 cents, 38 cents and 35 cents, and the delivery cost is 31 cents, 38 cents and 35 cents respectively.

The estimate for the draft beer delivery shows: Annual expense, electric, $3252; gasoline, $3854; two-horse wagon (two extra horses), $28.66. The daily cost is $11.40, $14.25 and $10 in the order named; the mileage cost is 37 cents, 43 cents and 46 cents, and the cost a call is 52 cents, 62 cents and 66 cents respectively.

The estimate for coal delivery is: Annual expense, electric, $3610; gasoline, $4380; three-horse wagon (two extra horses), $3135. The daily cost is $12.30, $16.20 and $11 in the order named; the mileage cost is 45 cents, 51 cents and 59 cents, and the cost a ton delivered is 54, 61 and 71 cents respectively.

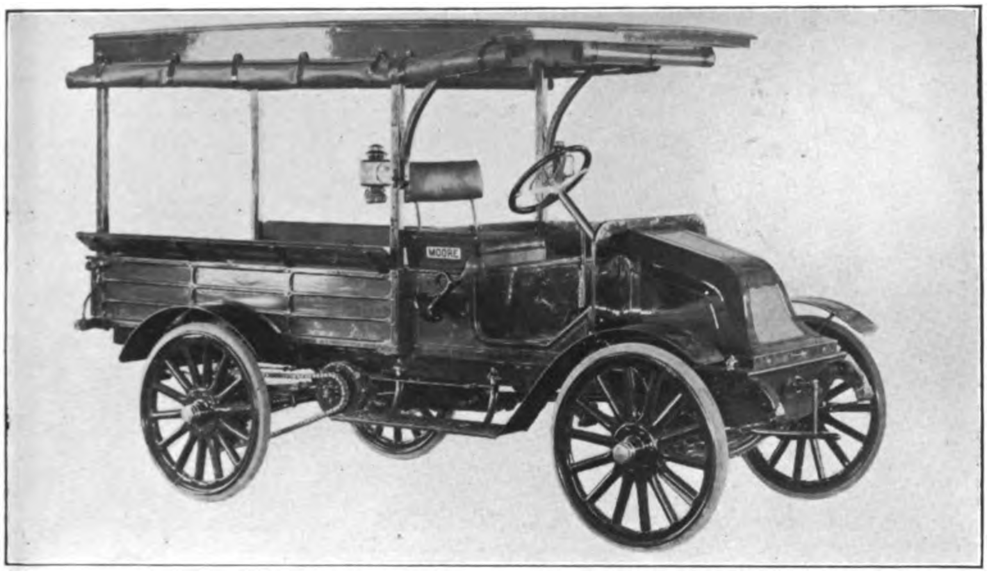
Copies of the bulletin may be obtained by request made to the department of electrical engineering of the Massachusetts Institute of Technology, Boston, Mass.

Tests were made recently at the factory of the Packard Motor Car Company with a number of trucks to determine the efficiency of the brakes and an automatic governor with which the machines were equipped. A loaded three-ton truck moving at the maximum governed speed of 12 miles an hour was stopped in less than the length of the machine, and an unloaded two-ton truck, driven to the limit allowed by the governor, was stopped in nine feet. The trials demonstrated that with liberal braking area and a governor by which the maximum speed of a vehicle may be fixed by the owner, there is very little chance for venturesome drivers to endanger the lives of pedestrians and property by driving at speeds beyond immediate control should emergency require the use of brakes. The tests demonstrate that with the large brakes in good condition, and with the speed limited by the governor, there is little possibility of accident in congested traffic if the machine is properly operated.

MOORE 1600-POUND DELIVERY WAGON.

THE Moore delivery wagon, built by the Palmer-Moore Company, Syracuse, N. Y., is maintained by the builder to be unusually efficient from an operative viewpoint, because of the small consumption of fuel and lubricant and the extreme flexibility of the motor. The capacity of the wagon is normally 1600 pounds, and this rating is applied to all forms of body built. The machine is claimed by the maker to be extremely simple, and constructed of high grade material by skilled workmen. The wagon is the first produced, but other sizes will be built as quickly as the manufacturing plans of the company can be completed.

The wagon is conventional in design as seen with the motor covered by the Renault hood, but examination of the motor shows this to be a decidedly unusual construction. It is designed and perfected by Edward Moore, a designer who is said to have worked 13 years before he produced the construction adopted for the machine. The motor is a three-cylinder, two-stroke cycle, air-cooled type, and it is installed in the chassis frame longitudinally. As constructed there are but few moving parts, the crankshaft, three piston and three connecting rods, and the port shutters being the entire operating mechanism of the motor.



The Moore Delivery Wagon, Capacity 1600 Pounds, Fitted with Standard Express Body.

The cylinders have a bore and stroke of four inches and these are cast with the heads integral with the combustion chamber in half-spherical form. The head has wide longitudinal fins that converge at the top and unite with a horizontal fin, and below this is a series of fins that extends nearly to the bottom of the cylinder. The cylinders are cast separately and have heavy base flanges.

The Moore motor differs from all other two-cycle motors in that it has a control by rotary port shutters that give variable speeds. The cylinders are the three-port type and each port has three rows of holes staggered in arrangement, the holes of the intake being smaller than those in the exhaust port. Each port has a rotary shutter that is so fitted that any row of holes or a portion of the area of any series of holes may be covered or uncovered. For instance, the shutter may be placed so as to vary the fuel that is supplied from one extreme to the other, and as this shutter is moved the shutters of the exhaust port and the by-pass are similarly varied, each shutter registering the same with reference to position. Because of the three rows of holes in each port the motor is said to have three speeds by change of fuel supply, low, intermediate and high, the maximum number of revolutions being 950.

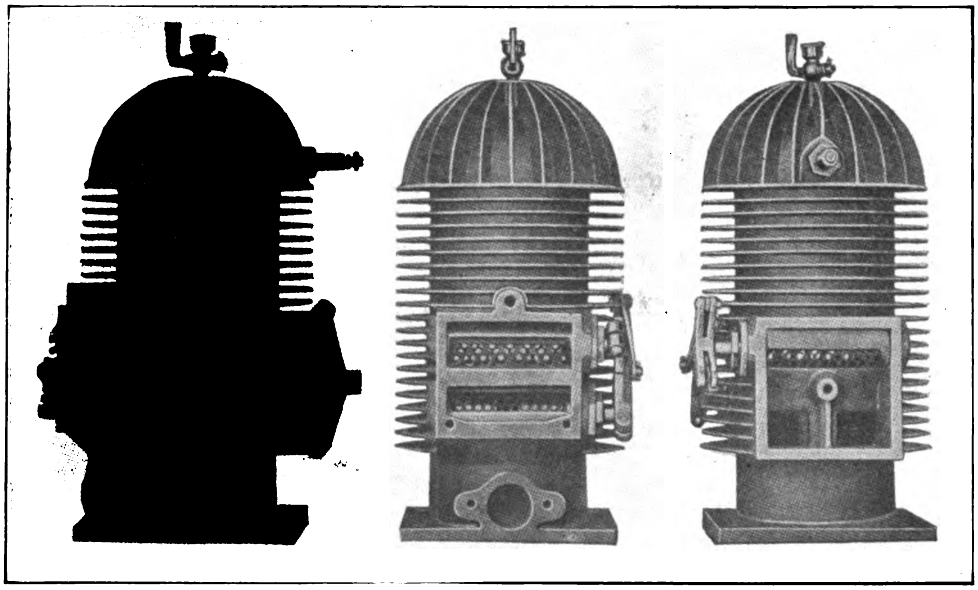
It is claimed for the motor that the speed may be regulated by the rotary valves so as to eliminate possibility of irregular firing or back firing at low speeds and to insure against loss of power at high speeds. The valves are operated by gear segments and bell cranks connected with a lever carried on the steering wheel, and the gear segments are made so that they will mesh in one position only, this construction preventing a possibility of wrong assembling. The shutters are installed with cover plates that may be easily removed for inspection or work. All parts of the motor are interchangeable. It is not necessary to remove the motor as a unit for examination or adjustments.

The crankshaft is very large and is mounted in die-cast bearings, the piston pin and the connection rod big end bearings being of similar material and of liberal proportions. The lubrication is by oil mixed with the fuel in the proportion of one quart of lubricant to five gallons of gasoline, this being sufficient even for the engine bearings, and there are no grease cups or oilers on the motor. The carburetor is a special construction there being a fixed adjustment. The ignition is by a Bosch high-tension magneto with a set position for firing.

The clutch is a multiple disc type and the drive is through a shaft having two universal joints carried in a self-aligning annular ball bearing mounted in a centre frame cross member, the universal joints between the bearing and the planetary gearset, that is assembled in combination with the jackshaft. The gearset gives one forward speed and reverse, there being an interlocking device so that it is impossible to engage either forward or reverse without disengaging the ratio in use. The jackshaft is a special type and is so mounted with the gearset as to be suspended at three points. The drive to the rear wheels is by side chains. The

radius rods have three swivel joints so as to compensate for any distortion of the chassis.

The frame is a pressed steel channel section with large cross members. It is carried on semi-elliptic springs, 38 by two inches forward and 40 by two inches rear. The axles are drop forged from vanadium steel, are I sections, both being 1.75 by 2.625 inches, and have spindles 1.625 inches diameter. These are fitted with roller bearings. The wheels are artillery type, fitted with solid 36 by 2.5-inch tires forward and 36 by three-inch tires rear. The drive is right side and the control is by three pedals, one for low speed, one for reverse, and one for the service brake, with hand levers located in the centre of the footboard operating the high speed clutch and the emergency brake. The control of the rotary valves of the motor is located on the top of the steering wheel, which is 18 inches diameter. The steering gear is irreversible, a worm and pinion construction. The brakes operate on 10-inch diameter drums on the jackshaft and the rear wheel hubs have two-inch faces. Both sets are equalized and are easily adjustable. The wheelbase is 102 inches and the overall length is 156 inches, the loading space of the regular express body being 82 inches length and 45 inches width. The gasoline tank capacity is 16 gallons.



The Rotary Port Shutters of the Moore Two-Cycle Engine, Showing Operating Mechanism.

BUYS MILL AND VILLAGE.

Goodyear Company Purchases Factory in Which It Will Make Tire Fabrics.

The Goodyear Tire & Rubber Company, Akron, O., has purchased a factory village known as Williamsville, in the town of Killingly, Conn., close to the Rhode Island line. The property includes a four-story mill 400 feet long, houses that will shelter 350 operatives and their families, a church, schoolhouse, store, assembly hall, large boarding house, a farm that will be cultivated for the benefit of the employees, Lake Alexandria, which is the local source of water supply, and the Williamsville Water Company.

The Goodyear company purposes to equip the mill with the most modern machinery, and will produce a large part of the fabrics for tires, hose and belting made by it, and besides having exclusive and uniform material will eliminate every expense that would ordinarily be incurred in buying from selling agents of mills.

ELECTRIC VEHICLES WANTED.

European Municipalities Investigating the Possibilities of Motor Equipment.

The bureau of foreign and domestic commerce of the Department of Commerce, Washington, D. C., will place at the disposal of manufacturers of electric vehicles the facts relative to the following opportunities for sales of machines aboard, these being designated by number: No. 10,984, a municipality which has need for two motor ambulances has authorized a medical official, on leave of absence in London, to examine different makes of electric machines, one to be used for general service and the other for the transportation of those stricken with infectious diseases. American dealers so desiring can send information to the London address of this official, or have their representatives visit him. No. 10,987, refers to a municipal engineer who is using an American electric truck in the transportation of city refuse. At the conclusion of the test, which is to continue a month, the engineer, if convinced of the suitability of the machines, may recommend the purchase of perhaps six of different makes, with the purpose of making comparison of them in continued service. From the result of this comparison of work the municipality purposes to purchase 25 machines. American manufacturers of electric trucks who wish to present the merits of their machines should send catalogues and other information, with the prices. Correspondence for both should be in English.

The Quartermaster-General's Department, U. S. A., at Washington, D. C., has issued blanks that have been submitted to prospective bidders to furnish any number of motor wagons of 3000 pounds capacity up to 10,000 accompanied by specifications of the machines that are required. These are, briefly, shaft drive, from 32 to 40 horsepower, with wheelbase from 120 to 144 inches, and either two or four-wheel driven.

TIRE WIDTHS AND LOAD WEIGHTS.

Conference of Interests Proposed to Secure Enactment of Satisfactory Laws.

George C. Diehl, chairman of the good roads board of the American Automobile Association, proposes that a conference be held by the leading state highway authorities and the manufacturers of motor and animal wagons for the purpose of discussing and drafting legislation regulating the width of tires used and the weights of loads to be carried on them, suggesting that when opinions had been obtained a committee could submit a general law that would probably be assured of passage wherever presented by the different legislatures, having as it would the recommendation of the differing interests.

After stating that few states have enforced wide tire laws, although it is known that narrow tires are destructive of roads, and that there is probability of skidding when wide tires are used, he proposes that if narrow tires be used on unimproved roads they should be prohibited on improved highways. He further maintains that the weight of loads should be limited because the bridges are not always constructed to carry traffic of what may be considered excessive weights. He believes that as it is impossible to reconstruct the existing bridges the loads should be well defined and the law enforced. Uniform law is suggested as the most equitable.

Any conference that could be arranged would simply be advisory, and even should all manufacturers of vehicles decide to build and equip wagons to specifications that would be approved, the several millions of wagons and machines in this country could not be changed save at material expense, and unless changed there would be no improvement of conditions. The agreement could only apply to what was produced by the builders and could have no bearing on vehicles now in use.

Then there is the trifling matter of enforcing the law, which would require the inspection of all tires and the weighing of wagons and their loads, whenever necessary, to say nothing of the almost uniform overloading by owners who absolutely disregard the requirements with reference to their own property.

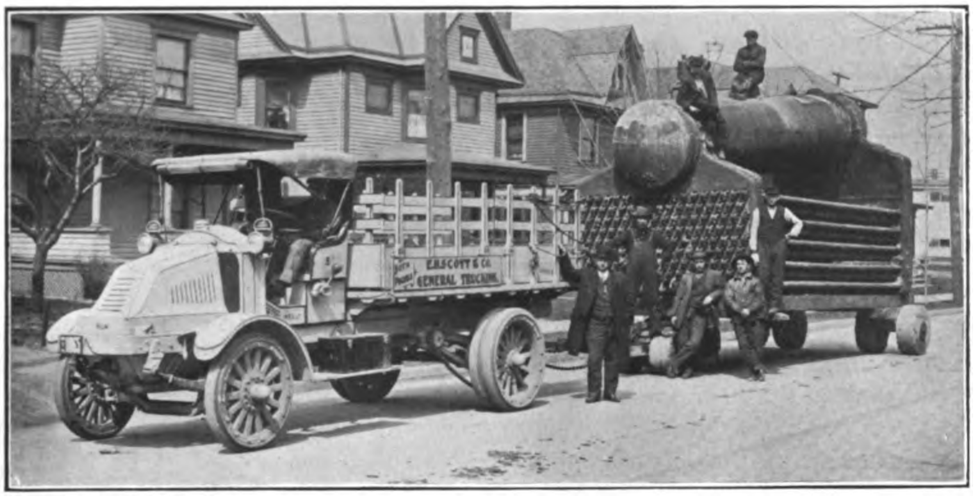
Edgar C. Neal has purchased a considerable interest in the Atterbury Motor Car Company, Buffalo, N. Y., and it is understood that he will be elected vice president of the concern and become an active factor in its management.

TRUCK HAULED 20 TONS.

Three-Ton Kelly Machine Drags Big Boiler Through Erie, Penn., Streets.

The hauling of a boiler weighing 20 tons through the streets of Erie, Penn., was an undertaking that directed much attention to the machine in that city recently. It was necessary to move the boiler a considerable distance to the plant where it was to be installed, and instead of resorting to horses and a special rigging it was proposed to haul it by motor truck. The proposition was made E. M. Scott of E. M. Scott & Co., agent for the Kelly machines, and he agreed to provide the motive power.

The boiler was jacked and under the corners at one end large dolly rolls were placed, while in the centre at the other end a third roll was placed, this supporting the construction at three points, and insuring a certain balance wherever the rolls were with reference to the road surface. A heavy chain was used for towing, and by the exercise of care the boiler was hauled through the streets by a three-ton truck without mishap. The saving of time was material, but the minimized handling was a factor quite as important.



Kelly Three-Ton Truck Hauling a 20-Ton Boiler Through the Streets of Erie, Penn.

The W. C. Hendrie Rubber Company, with capital of $100,000, has been organized at Torrence, Cal., where a factory is to be equipped for the manufacture of motor vehicle tires. The company has established branches at San Diego, Los Angeles, Oakland and San Francisco, Cal.; Portland, Ore.; Seattle, Wash.; Victoria, B. C., and it is probable others will be located in other western cities.

The United States postoffice department at Washington has issued invitations for bids on 20 wagons of 1500 pounds capacity and 20 tricars of 700 pounds capacity, to conform to specifications, the bids to be opened at 2 o'clock June 20 by the committee on supplies of the department. These vehicles will take the place of 100 machines contracted for by Postmaster-General Hitchcock, orders for which were cancelled.

BAY STATE TRUCK TAX BILL DEFEATED.

THE Massachusetts owners of motor service wagons were successful in their opposition to the bill advocated by the state highway commission imposing a tax of $5 for each ton capacity or fraction thereof. The bill was prepared by the commission and to this remonstrance was made by the Boston Commercial Motor Vehicle Association, the Boston Electric Motor Car Club, the Massachusetts State Automobile Association, the American Automobile Association, the Boston Automobile Dealers' Association and differing owners of wagons and trucks. The commission made agreement that a bill should be prepared that made the registration fee for the first ton $5 and $2.50 for each additional ton or fraction thereof. This bill could have been passed without opposition, but the commission attempted to force the passage of the original and this was regarded as a breach of faith that justified the endeavors of all interested in killing the bill. The bill had been reported favorably by the committee on roads and bridges, but was recommitted and hearing was given those opposing it. Again it was reported favorably, and it was passed by the senate by a vote of 19 to 18. The bill then went to the house and there it was defeated May 29 by a vote of 126 to 66, after a number of amendments had been proposed, one of which required a fee of $2.50 for the first ton capacity and $2.50 for each additional ton or fraction thereof.

Against this measure the agents for service wagons and owners of machines made a united campaign, and they were joined by several labor organizations. The remonstrants did not lack aggressiveness and they had an excellent organization and good legal advisors. One result of the agitation was to unite many business interests operating motor vehicles for protection against unjustified legislation and to well establish the fact that revenue and nothing else inspired the recommendation of the highway commission. In addition the service wagon owners are to be organized for mutual benefit, there being widespread approval of such organizing. One of the reasons for this is belief that the effort to tax business vehicles will be renewed in 1914, and organized endeavor must be made during the next campaign to defeat all candidates not favorable to what is considered equitable legislation.

The supreme court of Mississippi in a decision of May 29 declared the law requiring a license fee for the registration of automobile vehicles to be unconstitutional and void. This statute became law June 1, 1912, and it provided for the usual licensing according to horsepower—$5 for a machine of 25 horsepower or less, $15 for a machine of more than 25 and less than 40 horsepower, $20 for a machine of more than 40 and not more than 50 horsepower, and $25 for a machine of more than 50 horsepower. In its opinion the court holds that the legislature sought to collect an unreasonable tax under the guise of police power. This decision means that the state must refund all automobile licenses collected under the law, amounting to $28,115. This is the first state supreme court to decide that an automobile licensing law was unconstitutional. The New Jersey supreme court, in the case of a non-resident who refused to pay the license fee on the ground that it was a tax, and that the enforcement of the law was in violation of the federal statute governing interstate commerce which authorized a non-resident to pass through the state without payment of a fee, practically decided that the license fee required was not of such proportions as to be regarded as a tax. This implied that had the fees been such as are at present required, or such as the Mississippi law demanded, the determination might be that the fees were unconstitutional.

GIMBEL ADDS MORE WHITES.

Well Known New York Department Store Now Has 42 Wagons of This Make.

The sale of 16 White delivery wagons to Gimbel Bros., the well known New York City department store, announced by the White Company, Cleveland, O., is one of the largest motor truck installations of the year and it follows closely upon other large sales to New York stores, notably the delivery of 15 vehicles to Stern Bros. The 16 trucks purchased by Gimbel Bros. comprise an addition to a fleet of 26 White machines which have been in the service of the company for 1.5 years.

This increased installation is equally important from the standpoint of delivery efficiency, inasmuch as all of the 42 trucks are exactly alike, enabling the firm to take the utmost advantage of uniform design, as well as the accompanying simplicity of operating, garaging and maintenance. Gimbel Bros.' delivery department is maintained on progressive lines. The company's own men handle all adjustments and simple repairs. Not one of the White trucks owned by this concern has ever had to be sent to a White service station.

In their first month of service, the five KisselKar wagons, made by the Kissel Motor Car Company, Hartford, Wis., used in the parcel post delivery and collection system at Washington, D. C., have demonstrated their sturdy quality and fitness for the duty exacted of them. They have each averaged a daily mileage of 35, with 195 stops. No repairs have been required and although the motors are allowed to run constantly, the fuel consumption has been but one gallon to each 14 miles.

An order for six Stewart delivery wagons of 1500 pounds capacity has been received by the Stewart Motor Corporation, Buffalo, N. Y., from Pratt & Co., Buenos Aires, Argentine.

SEPARATE TAXES FOR SERVICE WAGONS.

States Where the Registration of Freight Carrying Vehicles Is Segregated from That of Passenger Cars---Special Requirements Relative to Speed, Weight, Etc.

THE owner of motor vehicles used for business purposes must regard the significance of the enactment of law by some of the states that means, if it means anything at all, the purpose of legislators to tax all machines so far as the owners will endure. The original intention of those who advocated and brought about the registration of automobiles was to have a means of identification and to establish responsibility for accidents. The payment of such a fee as would be legitimately used for the maintenance of a permanent bureau and meet the necessary expenses was not regarded as burdensome. Out of this policy was developed the taxation of motor cars, which it was maintained were destructive of roads. In many instances the fee has been increased to such proportions that it cannot be regarded as anything else than a tax, and, in fact, the purpose of the legislators is to create a fund and provide means for its expenditure.

In many states the service wagon has been taxed as has been the pleasure car, on the basis of horsepower. In others the fee is established without regard to capacity or power. While there are states that still do not require more than the cost of issuing the registration certificate, it is not to be denied that the disposition of the legislators has been to impose taxes, generally such amounts as to arouse vigorous protest.

Of the 49 states and districts of the United States, not considering Alaska or the island possessions, 12 have laws which segregate the service wagons from pleasure cars. In two states bills are now pending, or, if they have been made law, have not as yet become effective. The states where the registration fee is not the same as for the pleasure car are as follows:

Alabama—The law passed in 1911 provides that all motor vehicles used for public hire in transporting passengers or freight shall be licensed for a fee of $25. This does not require the licensing fee for the operation of machines that are used in the business of the owner, but imposes a tax upon those used constantly or casually in public service.

Connecticut—The law enacted in 1912 provides that service wagons of 1000 pounds capacity or less shall be licensed for a fee of $5, and that the fee shall be increased $2 for each additional 1000 pounds capacity or fraction thereof. This law may be repealed by a bill now pending before the legislature which requires a license fee of $7 for service wagons of 1000 pounds capacity or less, and increases the fee $3 for each additional 1000 pounds capacity or fraction thereof. The law now requires a fee of $15 for a three-ton truck, $23 for a five-ton truck and $33 for a 7.5-ton truck. The proposed law would tax these same trucks $22, $34 and $49 respectively.

Indiana—The law that became operative June 1 of this year requires a license fee of $5 for all service wagons without reference to capacity.

Maine—The law enacted in 1911 requires a license fee of $10 annually for all vehicles used for business purposes without regard to capacity. A law will become operative in that state July 11 of this year that prohibits the operation of any traction engine, trailer, motor or other vehicle upon or over any highway or bridge of the state, or the moving of any other object upon wheels, rollers, or otherwise, in excess of a total weight of nine tons, including vehicle or means of conveyance, without obtaining a permit from the Maine highway board, county commissioners, superintendents of streets, selectmen or road authorities, which permits may be general or limited as to time and the particular roads and bridges which may be used, and may contain any special conditions or provisions which in the opinion of the authorities are necessary; and the authorities are empowered to limit the speed of vehicles affected by the law to six miles an hour on any bridge by posting notice at either end. This law also prohibits the use of any flange, rib or any projection from a tire that will cut into or affect the surface of any highway, and the operation of any engine, vehicle or conveyance that has a weight of more than 800 pounds upon any inch width of tire, roller, wheel, etc.; or the operation of any vehicle carrying a weight of six tons or more, including the vehicle, at a speed of more than six miles an hour. The penalty is a fine from $10 to $500, to be paid to the town or city in which the damaged bridge or road is located, or to the county in the event of being in any unorganized township.

Maryland—The law enacted in 1912 requires a fee of $3 for the registration of all service wagons without reference to capacity.

Massachusetts—The law enacted in 1909 requires a fee of $5 for the registration of any service wagons without regard to capacity.

Michigan—The law passed by the legislature this year establishes a registration fee of 50 cents a horsepower of engine rating and does not regard capacity.

New Hampshire—The law now in effect establishes the following fees for registration: One ton capacity, $10; one to two tons, $12.50; two to five tons, $15; more than five tons, $20.

New Jersey—The law now operative requires a fee for registration of $4.50 for 10 horsepower or less, $7.50 for from 11 to 29 horsepower inclusive, $15 for 30 or more horsepower, and $10 additional for service wagons weighing more than 4000 pounds unloaded.

New York—The law enacted this year requires a license fee of $5 without regard to vehicle capacity.

Rhode Island—The law of 1909 requires a license fee of $2 without reference to capacity.

FEDERAL SOLVES PROBLEM.

Cherry Pickers in Oregon Now Find It Possible to Utilize Trucks.

A scarcity of transportation vehicles is usually apparent during the cherry picking season in Oregon, which lasts about three weeks. Most of the ranchers sell their crop as it stands upon the trees, and the purchaser must do all his own picking and shipping. The poor roads and trails make it difficult for a motor truck to reach the orchards in the highlands and burro caravans and pack horses have almost invariably been used.

Last year C. A. McCrary of LaGrande, Ore., used a Federal truck, made by the Federal Motor Truck Company, Detroit, and demonstrations in and around the mountains showed that this wagon could fulfill the requirements. Loaded with about 2200 pounds of camping paraphernalia, a 16-mile trip was made up the mountain to a large cherry orchard, where 10 days were spent. Every second day the truck carried its cargo of cherries 128 miles from LaGrande to The Core, where they were turned over to a local cannery. It is predicted that this year motor trucks will be used more in making these trips, because they not only save time, but are economical, none of the fruit being wasted by exposure to the sun as is true when horses and wagons are the only means of transportation.

If the plans that are now making are realized the Gramm Motor Truck Company, Lima, O., will produce 2000 of the Willys Utility type. The production of the factory will be largely given over to these machines. It is stated that 500 of these are now being constructed, and the remainder will be built during the year. The company now employs 400 men, and this number will be increased to 600 in a comparatively short time, which will nearly double the capacity.

ELECTRIC PASSENGER 'BUS.

St. Louis Department Store Utilizes Luxurious Vehicle for Its Customers.

A vehicle of unusual body design is utilized by the Famous & Barr Company, which conducts a department store in St. Louis, Mo., to transport its customers from the McKinley station to the store in that city, this being a convenience that has influenced a considerable volume of patronage. The round trip is exactly a mile and the 'bus has averaged 32 daily, with a maximum of 35, the weather and traffic conditions being the governing factor. The average number of passengers carried has been 450.

The 'bus has a standard General Vehicle two-ton chassis on which is installed a unique and ornate body, which was designed by a General Vehicle salesman, who was formerly in the service of the engineering department of the company. The body was built in St. Louis. The body has but one entrance, that being the sliding door that is shown in the illustration, and there are two folding steps which fall into position as the door is opened and are folded as the door is closed. The operating mechanism for the door is practically the same as is used for trolley cars, and it is controlled by a lever at the right of the driver, who may open or close the door without moving from his seat. The body is a fine example of coach work and it is lighted by windows at the sides and ends. The seats will accommodate 18 persons comfortably.

The Handsome Special General Vehicle Omnibus Used by the Famous & Barr Company, St. Louis, Mo., to Transfer Its Patrons from Station to Store.

The 'bus was placed in service with a view to bringing to the store persons who would otherwise have to walk or pay car fare, and it was desirable to have an appearance that would attract attention. This was the chief thought in working out the body design, and certainty of service as well as economy were essentials that impelled the use of the electric.

The Lincoln Motor Car Works, Chicago, Ill., had occasion to take about 100 wagons that were not equipped with tires from the works to a freight train for shipment, and after considering differing projects had four sets of tires made of manila rope, two inches diameter, which could be quickly removed after the machines had been placed in the freight cars, and installed on other wagons. The wagons were driven in groups of four to the freight yard, accompanied by another wagon, which brought the drivers and the rope tires back to the works, when the process was repeated. No rims were damaged and the expense of handling the machines was comparatively small, a total time of three days being required for the completion of the job.

ELECTRICS MAKE BIG MILEAGE.

Five Different Atlantic Machines Make Remarkable Records in Daily Service.

Five different Atlantic wagons and trucks recently made exceptional mileages in the course of service, and this without reaching the full capacities of the batteries. April 28 a one-ton wagon owned by A. Silz, Inc., 414-18 West 14th street, New York City, after making 51 miles as a day's work was sent out to tow in another make of machine, covering six miles more, or 51 for the day. It is estimated the battery charge would have carried the machine six or seven miles more.

May 7 and 8 a five-ton Atlantic truck owned by the Kips Bay Brewing Company, 57th street and First avenue, New York City, making deliveries on the east and west sides south of Bleeker street, made 52 miles on one charge of the battery and could have made eight miles more before the energy would have been exhausted. This truck has a battery slightly undersized.

May 14 a 3.5-ton Atlantic truck just completed for the General Chemical Company was sent with a full load for 61 miles over the streets of Newark, Elizabeth and Harrison, N. J.

May 15 a five-ton Atlantic truck, making deliveries for Picker Bros., wholesale wine merchants, 313 West 125th street, New York City, working in Brooklyn and lower New York, made 56.8 miles, the last 25 over slippery streets, and there was energy sufficient remaining in the battery for several miles.

May 16 a 3.5-ton Atlantic truck was sent from the Atlantic factory with a full load over streets in Elizabeth, Newark and Passaic for 30 miles. It was then unloaded and with a weight representing a standard body was driven over the same streets for an additional 59 miles, making a total of 99 miles. This performance is sworn to by Paul C. Diesing, the driver, who swears that the Stewart & Clark speedometer and odometer was in good working order and that the machine was not charged during the run. The truck was equipped with a 21-plate Hycap Exide battery. The average running speed was 9.25 miles an hour. This is the best record yet made by any Atlantic machine.

Standard sizes of Exide batteries were used in all of the machines to which reference has been made.

LARGEST PACKARD FLEET.

Figures Show New York Contractor Operates These Trucks at Cost of $10.20 a Day.

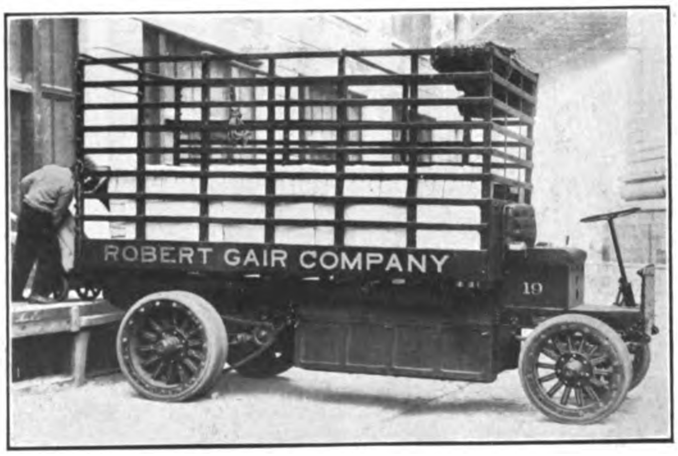
The average daily cost of operating one of the Packard trucks in the service of Oscar Daniels of New York City, is $10.20. This figure, which includes depreciation, interest and insurance, is taken from cost sheets covering the period from Nov. 1, 1911, to Oct. 31, 1912.

The contractor is engaged in the excavation of section 12 of Lexington avenue subway from 111th to 118th streets.

Eight three-ton trucks, equipped with special dumping bodies, are loaded from a hopper, thus reducing to a minimum the time required for this work. The material is hauled to the East river at the foot of 110th street. The entire distance covered does not exceed one mile for the round trip. Each truck hauls three cubic yards to the load and completes 24 trips in eight hours. The scheduled time for the completion of this job is three years.

Using eight trucks, the company completed 38 per cent. of the work in 10 months' time. Continuing at this rate it will be able to finish the work about one year ahead of schedule. An order for 10 additional trucks makes a total of 18 purchased by the company of the Packard Motor Car Company, Detroit, and makes the largest fleet of Packard trucks in the service of any one contractor.

A. P. Foss of Lakeside, Cal., a fruit grower, utilizes a model H Reo wagon, made by the Reo Motor Car Company, Lansing, Mich., to haul fruits to the railroad



A Five-Ton Atlantic Electric Truck Fitted with a Crate Express Body That Is Protected by Tarpaulin Covers.

station and do other work on the farm until late in the fall. Last year, at the conclusion of the summer's work, the machine was used on a tour to Orville, Butte county. The trip lasted a month, during which Mr. Foss says he travelled 1400 miles with an expense of 10 cents for repairs. The 1500-pound machine has been in service one year.

John Swincoe, formerly chief engineer of the Driggs-Seabury Ordnance Corporation, Sharon, Penn., has associated himself with the Weston-Mott Company of Flint, Mich., maker of motor vehicle axles, etc.

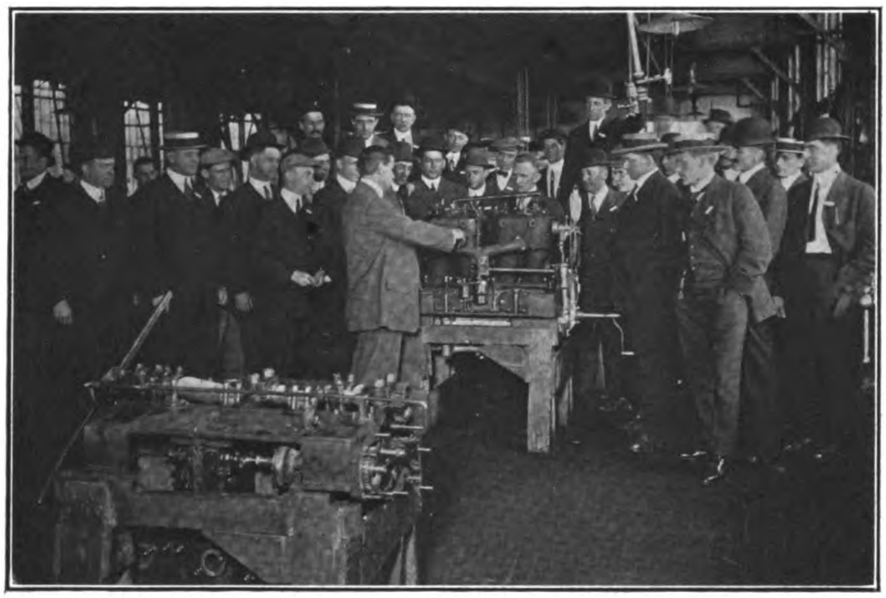
Much valuable information for all owners and users of motor vehicles is contained in a booklet entitled "The Care of Leaf Springs," published by the Sheldon Axle Company, Wilkesbarre, Penn., which will be sent to any person sending request to company's office.

BRIEF NEWS OF MANUFACTURER AND THE TRADE

The Knickerbocker Motor Truck Manufacturing Company, New York City, has completed arrangements for issuing new stock and has already sold $250,000 of its issue. The intention is to erect a larger factory in the Bronx, capable of turning out about 150 trucks a year, which is about treble the present capacity.

Carl G. Fisher & Co., and the Hunter-Hammond Auto Company, both of Indianapolis, Ind., have combined their interests and have incorporated the Fisher Automobile Company with capital stock of $25,000. The new concern is composed of the following: President, Carl G. Fisher; vice president, Harry L. Hammond; secretary-treasurer, F. Ellis Hunter. The headquarters will be at 400 North Capitol avenue, formerly the headquarters of Carl G. Fisher & Co. The firm will handle Reo, Stutz and Packard pleasure cars and Packard and Reo trucks.

Teaching drivers of motor trucks to know the abuses of overloading and fast driving was one of the chief purposes of the service convention at the Providence, R. I., factory of the American Locomotive Company, May 27-28, which was attended by about 50 men from New York, Chicago, Philadelphia, Boston, Pittsburg, Richmond, Newburgh, N. Y., Montreal and the Pacific Coast. George H. Duck, manager of the general service department, was chairman, and the speakers included General Sales Manager C. Arthur Benjamin, Factory Manager F. P. Nehrbas, Chief Engineer R. A. Vail and J. F. Gfrerer, manager of the dealers' service department. Economy of operation was the object sought by each speaker. Besides hearing the addresses the visitors inspected the factory and witnessed demonstrations of the construction of the machines.



Delegates to the Service Convention Held May 27-28 at the Providence Factory of American Locomotive Company, Listening to a Lecture on Alco Truck Motor.

William E. Barker, formerly president and treasurer of the Enterprise Rubber Company, Boston, Mass., has been appointed sales manager of the United States Rubber Company, with offices at New York City.

W. H. Harsh, formerly general manager of the Kelly Island Lime & Transportation Company, has been appointed assistant general manager and assistant treasurer of the Sandusky Auto Parts & Motor Truck Company, Sandusky, O.

The production of the Brown Commercial Car Company, Peru, Ind., has been materially retarded by the conditions that have resulted from the inundation of that section of the state last March. It was necessary to do much additional work on machines damaged in the flood, and material has been received slowly because of similar retardation of other factories. Not only this, many of the stockholders have been compelled to give attention to other enterprises, so that while cooperation has brought about excellent results, time has been required for the company to resume its former productiveness. The Brown wagons in service have given a very large measure of satisfaction and the prospect for the company now appears very bright.

The Electric Home, San Diego, Cal., has occupied its newly erected garage at 3227 Fifth street. The company also has opened an agency for the Waverley electric cars, made by the Waverley Company, Indianapolis, Ind. W. L. Lowe and H. O. Hattel are the proprietors.

C. F. Kircher has been chosen manager of the truck department of the Pacific Car Company, Seattle, Wash.

George Walker, formerly sales engineer of the Muncie Gear Works, Muncie, Ind., is now chief engineer of the Benton Motor Car Company, Benton, Ill.

Charles Basle, the racing driver, has been secured by A. H. Sowers to take charge of the assembling plant of the Sowers Motor Truck Company, Boston, Mass.

M. A. Magee, who for several years has been connected with the Motz Tire & Rubber Company, Akron, O., maker of Motz tires, has succeded P. M. Pontius as sales manager. Mr. Pontius is specializing in the work of the electric vehicle tire and is now officiating as the manager of that division.

Carl Neracher, chief engineer of the Willys-Overland Company, Toledo, O., maker of Overland machines, has gone to Europe for a needed rest. Incidentally he will examine European conditions and engineering practise.

W. H. Lally of the export department of the Studebaker Corporation, Detroit, maker of Studebaker pleasure and commercial vehicles, has returned to Detroit after a trip of six months around the world, during which he visited nearly all the Studebaker agencies.

The Chambray Carburetor Company, Detroit, was recently incorporated with $50,000 capital stock, the name of the concern being a combination of part of the names of two of its chief incorporators, who are as follows: John H. Chambers, John W. Mowbray and Charles H. Bennett.

The Wallis Tractor Company, Milwaukee, Wis., formed with $800,000 capital, has rented the factory buildings located on East 72nd street, near Clair avenue, formerly occupied by the Royal Automobile Company, and will manufacture traction engines on a large scale. H. M. Wallis, Sr., and H. M. Wallis, Jr., are the main stockholders.

The B. F. Goodrich Company, Akron, O., maker of Goodrich tires, has encountered such a demand for its product in Canada that it has been decided to build a large factory to supply the Canadian needs. Thirty-two acres of land have been secured at Saint Catharines, Ont., conveniently located for the handling of traffic by railroad, and the new factory will be modelled on the lines of the parent Akron plant. When fully developed it is planned to employ at least 1000 men, with ample provision for future expansions.

The Grant-Lees Machine Company, Cleveland, O., has been reincorporated under the name of Grant-Lees Gear Company. This is to express more concisely the chief activities of the company, which recently made several large additions to its plant.

The Ralston Motor Company, Omaha, Neb., has amended its articles of incorporation and is now known as the Omaha Tractor & Engine Company. The capital stock is $500,000 and the incorporators are: H. E. Johnson, H. K. Burkett, Isaac Kahn, Gottlieb Brunnenkant and E. C. McGilton.

The Wagenhals Motor Car Company, Detroit, maker of a three-wheel commercial car, has increased its capital from $100,000 to $500,000, and will locate in a much larger plant in order to increase its output. William Pflum of Dayton, O., formerly manager of the National Cash Register Company, is interested with Mr. Wagenhals and is preparing to take an active part in pushing the company's product to the front.

Ray Longacre has joined the sales department of the Star-Tribune Motor Sales Company of Detroit, distributor of Star trucks and Tribune pleasure vehicles.

The Mansur Motor Truck Company, Haverhill, Mass., has been formed by George B. Mansur, Kirke L. Moses and Nelson L. Forbush, with capital stock of $30,000.

N. S. Hopkins has resigned his position with the American Locomotive Company's automobile plant at Providence, R. I., where he had charge of the main manufacturing department.

The Chicago Universal Motor Truck Company has been incorporated at Chicago with capital stock of $10,000. Those interested are E. C. Rockwell, James H. Dunn and C. M. Stevens.

The Hillman Taxi Service Company, Mobile, Ala., has incorporated with $2000 capital stock, of which $1000 is subscribed. The incorporators are George D. Hillman, Mary F. Hillman and Rosina Hillman.

The De Dion-Bouton Selling Branch, New York City, has moved its showrooms to 1612 Broadway, on the northeast corner of 52nd street. The garage and repair department is located at 110 West 54th street.

The Palmer-Meyer Motor Car Company, St. Louis, Mo., maker of Palmer trucks, has appointed the following agents: Louis Schnellman, Luxemburg, Mo.; Henry J. Jenneman, Mattese, Mo.; C. J. Siedler, Maxwell, Mo.

Glenn W. Barden has been appointed secretary and treasurer of the Kelly-Springfield Motor Truck Company, Springfield, O., maker of Kelly trucks. He was formerly auditor of the Warren Motor Car Company, Detroit, maker of Warren cars.

M. E. Morris has been appointed Pacific Coast manager for the Goodyear Tire & Rubber Company, Akron, O., to succeed W. T. Powell, who has resigned. F. E. Carroll remains manager of the local branch at San Francisco, Cal.

Joseph Tracy, consulting engineer of New York City, has again moved his laboratory in Rutherford, N. J., to larger quarters as a result of the increasing demand for demonstration and development testing. At the new plant six to eight motors may be tested simultaneously.

The Knox Automobile Company, Springfield, maker of Knox trucks and the Knox-Martin tractors, is to transform its representation at Boston from an agency to a branch office, which will be in charge of Frank B. Crockett, who was formerly connected with the Underhill Company in that city, the Boston agent for the Knox company since 1901.

The Kelly-Springfield Motor Truck Company, Springfield, O., maker of Kelly trucks, is to establish an assembling plant at San Francisco, Cal., according to Charles B. Shanks, general sales manager, who recently made a trip to the Pacific Coast to investigate the situation. The new plant will supply the demand for the Kelly product west of Denver, Col.

The Pittsburg Taximeter Company, Pittsburg, Penn., one of the largest makers of taxicab meters in the country, recently closed contracts to equip all the machines owned by the Detroit Taxicab & Transfer Company and the cars of the Cleveland Taxicab Company. The company also has a large order for its product to be shipped to Rio de Janeiro, Brazil.

The Stewart Motor Corporation, Buffalo, N. Y., recently appointed the following dealers to handle Stewart light delivery cars: Fred H. Van Dorn, Red Bank, N. J.; Draper Garage, Northampton, Mass.; G. E. Clark, Herkimer, N. Y.; H. B. Gray Company, Fort Plain, N. Y.; Johnstown Motor Car Company, Johnstown, N. Y.; William Petry Garage, Hudson, N. Y.

H. B. Willower, who has for the past two years represented the Gramm Motor Truck Company, Lima, O., maker of Gramm trucks, throughout Illinois, Indiana, Kentucky and Michigan, has joined the sales staff of the Gramm-Bernstein Company, Lima, maker of B. A. Gramm's trucks. Mr. Willower is one of the most successful salesmen in the motor truck field.

William Sternberg, engineer of the Sternberg Manufacturing Company, West Allis, Milwaukee, Wis., maker of Sternberg trucks, recently sailed from New York City for a tour of Europe to last several months. He expects to make the trip one of business and pleasure, visiting the more important points in the manufacture of motor trucks abroad, and investigating closely the features and conditions of the industry in general.

B. F. Schmidt and L. R. Ingrabrand have been advanced from foremen's positions to those of superintendent and assistant superintendent, respectively, in the factory of the Speedwell Motor Car Company, Dayton, O., maker of Speedwell motor cars and trucks. Both men have been with the company since its inception. The former was foreman of the chassis assembling department and the latter of the final assembling department. Jacob Neibert succeeded Mr. Schmidt as foreman of chassis assembly. The changes came as the result of the resignation of Superintendent Dunston.

The Pacific KisselKar Branch is having plans drawn and will soon break ground for a new sales and service building to be located on Van Ness avenue, San Francisco, Cal. It is intended to erect a structure that will eclipse in size and completeness the big KisselKar service station recently opened at Chicago, which contains 70,000 square feet of floor space.

L. S. Crane, Atlanta, Ga., announces the removal of his business to 328 Peachtree street, where will be carried a complete line of Pope-Hartford automobiles and trucks, motorcycles bicycles, lubricants, etc.

The Adams Bros. Company, Findlay, O., maker of Adams trucks, has designated the following new agencies: Holcomb Company, New Haven, Conn.; Fisher & Lambine, Kittanning, Penn.; Charles R. Roehl, Caracas, Venezuela; Cuba Electric Supply Company, Camajuani, Cuba.

LUBRICATING OIL.

(Continued from Page 414.)

The motor after leaving the factory is run at great variations of speed and considerable variation of load. These variations are quite rapid and frequent. On account of the mechanical conditions of the motor you have recommended a very thin, light lubricating oil for the motor, under the guarantee. This lubricating oil has no particular adhesiveness and will flow as readily from the cylinder wall as to it. Consequently, during the rapid and frequent variations of speed, cylinder walls are sometimes overburdened with oil and sometimes practically dry, making wear and tear excessive and naturally resulting in a very rapid increase in the space between the piston and cylinder wall. This wear and tear is not thoroughly even; the clearance is larger in some places than in others. Then the lubricating oil flows freely up and down the walls of the cylinder and there is never any time when just the proper amount of oil is on the cylinder wall. The oil is so thin that it cannot be held in the increased space, consequently on the compression stroke the gasoline mixture escapes past the piston, destroying the lubricating oil in the crankcase, and reducing from 15 to 30 per cent. the power which should be secured from the gasoline.

Further, the condition under discussion is responsible largely for the carbon which is so constantly being experienced on account of the fact that the oil, being very light in body and free flowing, is drawn up during the suction stroke into the compression chamber and on to the piston head, where it is distilled, leaving a coke baked on the piston head to the first ring, upon the valves, etc.

Consider instead of the mechanically secured compression used in connection with thin oil, compression which depends upon the use of lubricating oil, the clearances being larger. From the standpoint of the mechanical efficiency of any power generator, and, in fact, any moving equipment, the best fit—that is, the mechanical fit which absorbs the least amount of power due to friction in the power generator itself—is an easy sliding fit. If dependence is to be laid, however, upon the metal and not upon the lubricating oil to maintain compression, this easy sliding fit is too loose to give the compression required. If, however, it is intended to secure the compression by the liquid seal of the lubricant, then an easy sliding fit can be given to the motor, a sufficiently heavy-bodied oil used for lubricating with the result that the metal surfaces can be kept apart, the compression can be maintained so that there will be practically no change in the lubricating oil in the crankcase and only the ordinary wear and tear on a properly lubricated surface will take place, which wear and tear is infinitely slower than the wear and tear which usually occurs under the conditions previously mentioned.

Nevertheless, it remains true of all our tests, experiments and information that the general practise of the motor manufacturer in this country has been to use clearances between piston and cylinder wall which were entirely too small and to use lubricating oil which was entirely too thin. This was undoubtedly due to the attempt to get away from carbon troubles and gummy deposits, but a little reflection will show that the excessive carbon troubles are mainly to be connected with too thin an oil. While oils from some crudes, of course, give only soot, and other oils give coke when burnt in the combustion chamber, the carbon in each case is due to the presence of oil where it has no business to be and where under proper mechanical conditions it would not arrive. Provided the oil has sufficient body to adhere to the cylinder wall and the piston rings so that at all times a perfect, or practically perfect, seal is maintained practically no oil should get up into the compression chamber, onto the valves or the piston head, inasmuch as if the oil has sufficient body to adhere to the cylinder walls during compression it will have no tendency to climb during the suction stroke, and consequently at no time will there be any large amount of excess oil where it will be affected by combustion. I have no doubt whatever that the motor manufacturer has in the past made a mistake in pressing the oil companies to give him a product which would not deposit any carbon, instead of examining the mechanical conditions of his motor and finding out whether it was necessary to burn oil. Under some conditions it is impossible to avoid carbon. The character of the carbon depends partly upon the character of the crude, the method of refining and the character of the oil made necessary by motor mechanical arrangements, but the cause of the continued presence of excessive carbon and continual trouble with carbon should be looked for, it seems to me, in the mechanical conditions of the motor. When these mechanical conditions are examined it will be more fully determined that we have not been securing the economy which should be secured from the fuel or the lubricating oil and that the depreciation due to excessive wear has been too rapid.

The
MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., JULY, 1913 No. 7

BOSTON'S DELIVERY PROBLEM.

Distribution by 367 Recognized Express Companies, 343 of Which Are Purely Local, and Few Are Motorized—Big Department Stores Have Some Motor Equipment, but Only One with Facilities for Quick and Economical Loading.

By William W. Scott.

THE MOTOR TRUCK has undertaken a survey of the transportation conditions in many of the large cities of the country with a view of giving facts that will show what must be dealt with by not only the manufacturers of vehicles, their agents and representatives, but the business men and the people as a whole, for it is evident enough that only through a thorough understanding of the needs of each locality the solution that will eventually lead to realization of economies can be reached.

In cities of such size to justify the designation of commercial centre there are many active enterprises, and those directing them usually regard the conditions met with so far as they relate to their own businesses, but these men have no concern in the effect these conditions may have with reference to their competitors and associates. They may be conversant with their own service and with others that may be available in the event of need, but few, if any, have occasion to ascertain actual facts as to the volume of transportation, the number of concerns engaged in transporting goods and commodities, of the co-operation and methods of transfer, the detail of handling, the times of delivery and collection for shipments and the manner in which deliveries are made by the receiving companies. The value of information of this character is so great that it cannot be overestimated.

Shipping Room Crew at the Houghton & Dutton Store, Boston, Sorting the Packages for Distribution into the Bins Assigned to Each Route and Vehicle.

It is evident that distribution by the enterprise, whatever it may be, is proportionate to the requirements of its patronage. The manufacturer of the motor wagon and truck bases his business on the knowledge that these demands exist, but it is his work to produce what will serve those requiring conveyances, dealing with manufacturing and designing, and depending upon his sales department to dispose of the machines produced. The sales manager in turn looks to his branches and representatives to so demonstrate the economies of motor haulage that he can sell the production of the factory.

The men selling trucks are assumedly educated to the qualities and merits of the vehicles they sell, though oftentimes they are not as well informed as good judgment would demand, and their purpose is to approach business men and convince them of the value of the machines from their points of view. In the event of sales the purchaser is frequently left to work out his own problems, and the salesman goes along to another prospect and endeavors to make another sale. The buyer of the vehicle may have been careful enough to have studied his work and planned the use of the machine to get what appears to him to be the most that is practical or possible, but unless he has intimate

Houghton & Dutton Shipping Room, the Crew Distributing the Packages into the Bins Ready for the Coming of the Vehicles.

The shipper follows the policies of his superiors and he conducts his service with reference to the demands, he having the control of his drivers in the actual vehicle delivery and dictating what other method of transportation shall be used. He is guided by his training and knowledge, and by his experience, and, sometimes, prejudices.

If the truck salesman had the knowledge of the shipper of each establishment he would be ideally qualified to deal with each individual problem. Those who purchase vehicles have not usually detail of service in mind. In fact they are frequently only generally informed. They leave to those in charge of this work the supervision and administration. It is rare that they have occasion to go into this subject deeply. The truck salesman cannot go into the actual detail of transportation improvement with those who have no intimate knowledge of that detail, even were he qualified to do so, but if he has the broad understanding of all possibilities of locality service he can demonstrate the usefulness of the motor equipment clearly and logically. While it is not reasonable for all salesmen to acquire this information sufficiently to apply it equally well to every form of transportation, it is entirely practical for those directing sales in the territory to give such attention to each business requirement as will make possible the working out of tangible plans for improvement, such as can be used by the salesmen to good advantage.

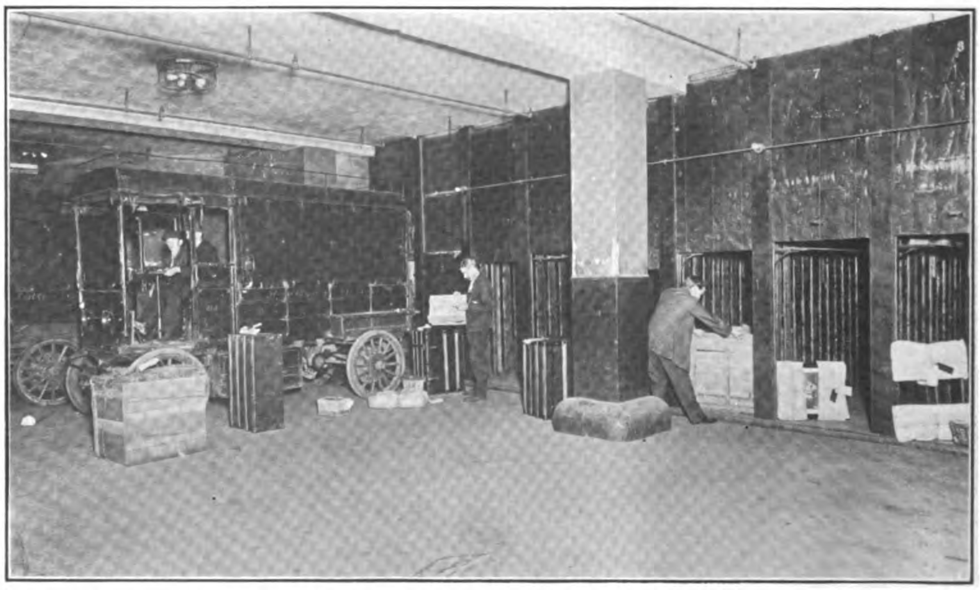
There are, of course, many aspects from which highway haulage can be considered. Each business

knowledge of his service and can direct his men so they will keep the equipment busy, the promised economies are not realized. Without opportunity to study the transportation service of others, or capacity to adapt and develop methods, or resources to install facilities, it is not possible for the truck or wagon owner to bring about a material saving, while the neglect or abuse of the vehicles may entail loss that cannot be compensated.

The average motor truck salesman is not a transportation expert. There are those who are abundantly qualified to investigate a service and devise means for material improvement, but such men are rarely met with. Without the practical knowledge of the conditions—and this ought to include every aspect—no man can successfully advise the man who wants information and instruction. No matter how well versed the salesman may be mechanically, and mechanical experience is not underrated, he cannot give the positive and specific facts so much needed unless he has carefully examined into each case and made conclusions that are substantially founded.

Dependent Upon Others.

But there are few establishments that depend entirely upon their own transportation departments. With rare exceptions these are more or less dependent upon other facilities, and generally the shipping is in charge of a shipper who is expected to be responsible for delivery. He utilizes whatever services are at his command, and while he may have no voice in purchasing equipment, other than making recommendation, he is expected to produce the largest possible results with the least expenditure of money.



The Houghton & Dutton Store Garage and Loading Department, the Shippers Handling the Goods for the Two Electric Wagons—This Is the Only Shipping Room in a Store Building in Boston.

Entrance to the Garage and Shipping Room of the Houghton & Dutton Store from Ashburton Street—Climbing a Run the Department is on the Third Floor from the Tremont Street End of the Building.

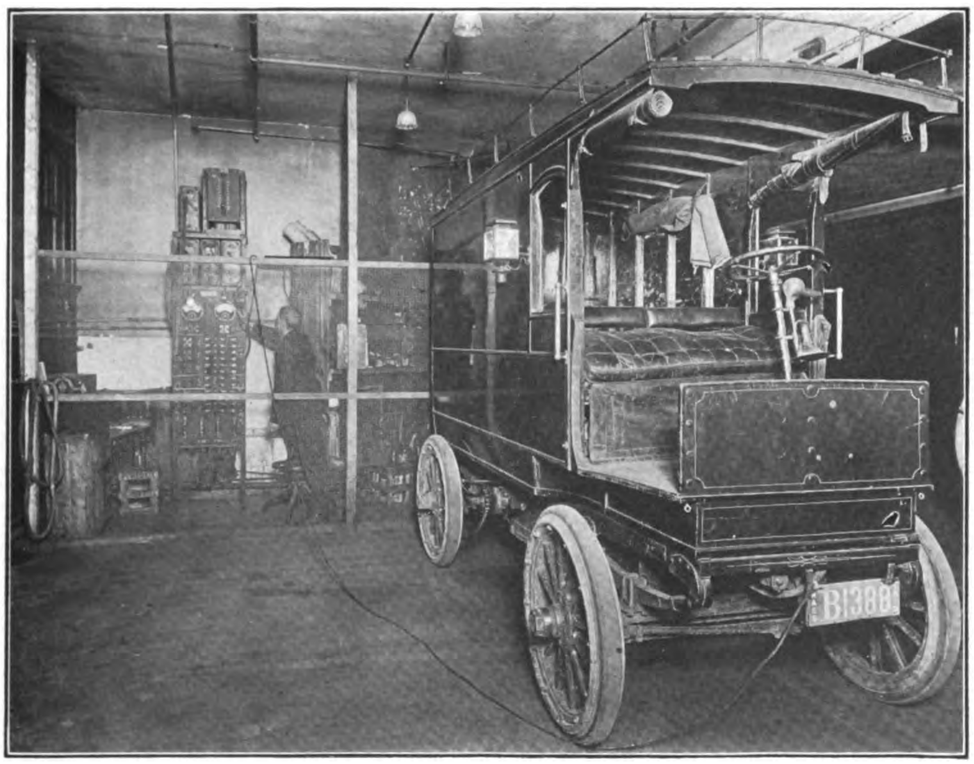
must receive its stock and make its deliveries, though there are cases where selling representatives have stock shipped from factories, shops and mills that are not handled by them, these shipments going direct to the buyers and being either hauled by him or are delivered to them. All business men do not haul their receipts of stock, and while a comparatively larger number make delivery, a considerable part is handled by concerns that specialize in this work.

Factor of Advertising.

Then primarily the problem is whether or not it is economical to maintain a transportation equipment. If there is sufficient work to justify this then the question is the character of vehicles to use. Theoretically no man ought to consider utilizing any form of conveyance unless it is profitable to do so. There are thousands, however, who regard the movements of a vehicle in the streets as having an advertising value. This factor is worthy of consideration, but strange as it may seem no charges are made against advertising appropriations and no credits are given the delivery expense accounts for this service. While with some concerns the actual cost of maintenance is considerably increased through the necessity of maintaining the appearance desired to secure the greatest benefits of highway advertising, no valuation is placed upon this appearance and the delivery department is charged with this expense. As a matter of fact there should be a revenue credited for this appearance.

Though it may be believed that this advertising factor is of small importance, there is no question whatever that some firms regard it sufficiently to pay what may be regarded as large prices for it. Some have developed business in localities from which patronage was not drawn by having their vehicles driven through the streets, and making no announcement whatever, depending upon the people observing the wagons to accept the fact that delivery would be made, and inaugurating services without custom, or a very limited demand. This has been done repeatedly by metropolitan stores in cities and towns many miles distant with excellent results.

Returning to the primary problem, that of maintaining a transportation equipment, the volume of haulage in receipts from differing sources at the expense of the firm and the volume of stock that must be delivered is the basis for determination. Stock is bought either f. o. b. or delivered, and in any event the haulage cost must be paid. Freight must be hauled and express may be either prepaid or collect, but the charge for expressage is included in the selling price. Where stock is manufactured locally it may be delivered, but here again the item of delivery cost cannot be avoided.



The Electric Garage and Charging Station in Connection with the Shipping Department of the Houghton & Dutton Store, the Panel and Stock Room Being Behind the Wire Partition.

Avon Street, Between the Main Store (at Right) and the Annex (at Left) of the Jordan, Marsh Company, Looking Toward Washington Street, Showing the Awaiting Vehicles of the Customers.

creased business. So far as attracting the public by advertising is concerned, this applies to the retail shops and stores, and generally these are the large establishments, for the most enthusiastic publicity advocate will admit that the proportion of those doing business who can be classed as local advertisers is small, and the non-advertisers are generally those whose business is limited because of innumerable reasons.

As has been stated, the transportation equipment of a store or shop is necessary only when it can be worked to realize its full value. But there are equipment units to be considered and the question is always to provide for the requirements in excess of one unit and not sufficient for another. Generally speaking such excess is provided for by such service as may be maintained by others, and this paves the way for the local carriers, which are classed as expressmen.

Then if the proportions of the business warrant the haulage can be done at less expense than for contract or intermittent service.

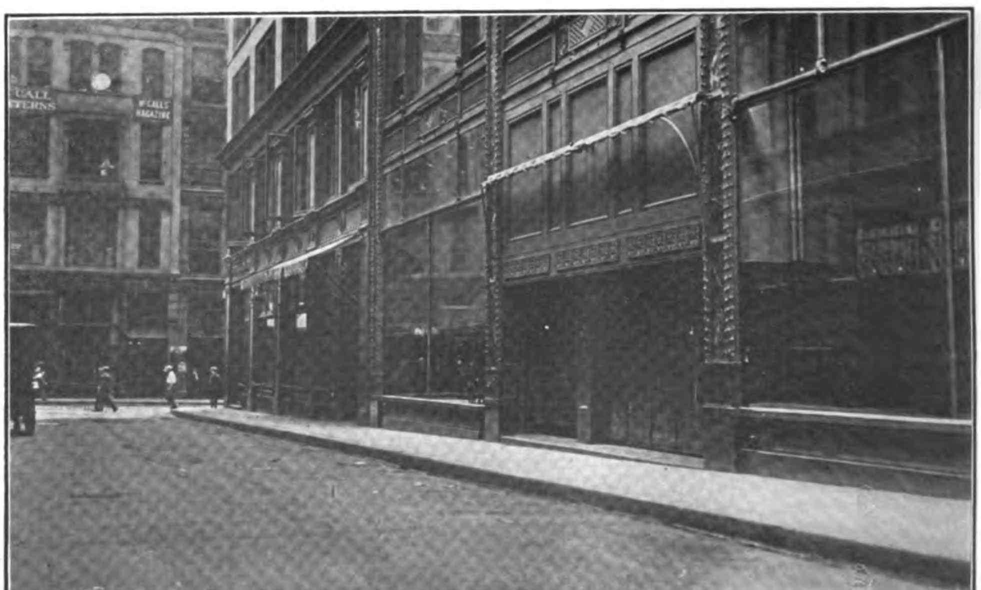
Location Is Important.

In the eastern cities of the country, where the business sections have been generally developed in the older parts of the communities the streets and highways are usually narrow. The new sections have much better planned ways, but business houses and manufacturing establishments cannot be changed because removal would entail large expense for construction and equipment, transactions would be interrupted, and there would be in all probability longer haulage. The location is a very potent factor in merchandizing because of the means taken to attract purchasers, for it will be acknowledged that advertising is a mighty influence with the public and the disposition of every person is to secure the greatest value or quality for the price paid. While it will be admitted that this statement is applied specifically to department stores, it is also a fact that the most successful business houses are those that are widely known, and reputation and prestige is proportionate to public knowledge.

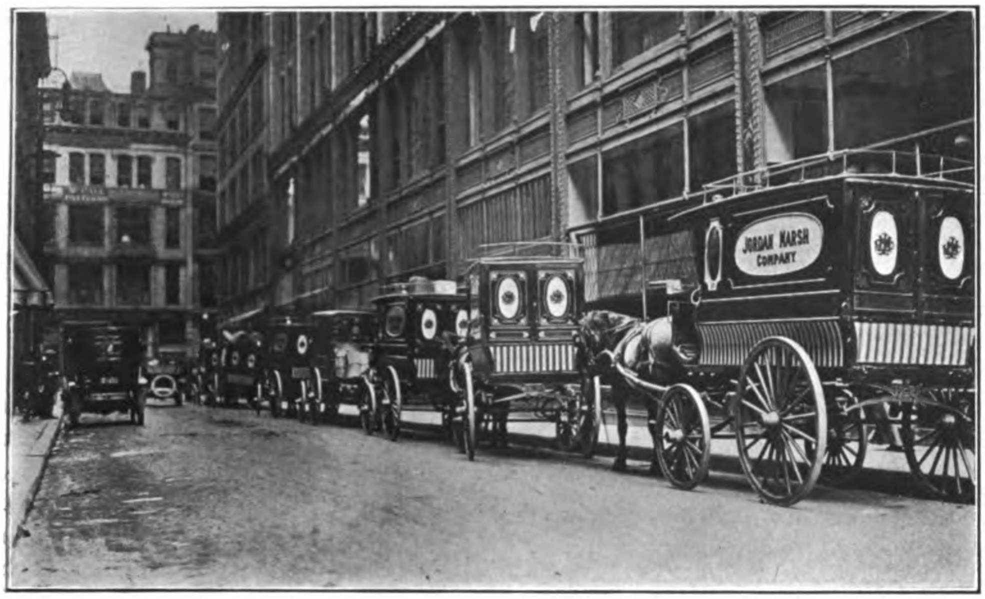
The public has been educated to buying at what are believed to be opportunities, and so much are these "sales" regarded by the people that an announcement will influence thousands to "shop" and perhaps purchase heavily, where the concern with goods and prices equal and undoubted reputation would realize no in-

Necessity for Delivery.

There are thousands of shops that do exclusively a locality business, where the goods are carried away by the purchasers, or occasionally packages are sent out by messengers or by expressmen. The larger the volume of transactions the greater the number of deliveries. Dealers in bulky goods must of necessity make deliveries and such concerns must either have transportation departments or have the work done by contract. Competition of business houses impels delivery of goods, this being a convenience that is always ap-



Avon Street, Looking Toward Harrison Avenue, Showing the Two Main Delivery Doors of the Annex of the Jordan, Marsh Company (the Second Beyond the Second Window in the Illustration) Where the Greater Part of the Delivery of Packages Is Made to the Wagons.



Line of Horse Wagons in Avon Street Awaiting Loading at the Two Delivery Doors, Which Are at the Sixth and Seventh Wagons.

preciated. Some firms will deliver any purchase within a definite radius and will ship by freight, express or mail with the charges prepaid anywhere in the United States when the purchase is or is more than a stated amount. Others will deliver packages within a radius of from 75 to 100 miles the morning following the purchase, with their own or by special service.

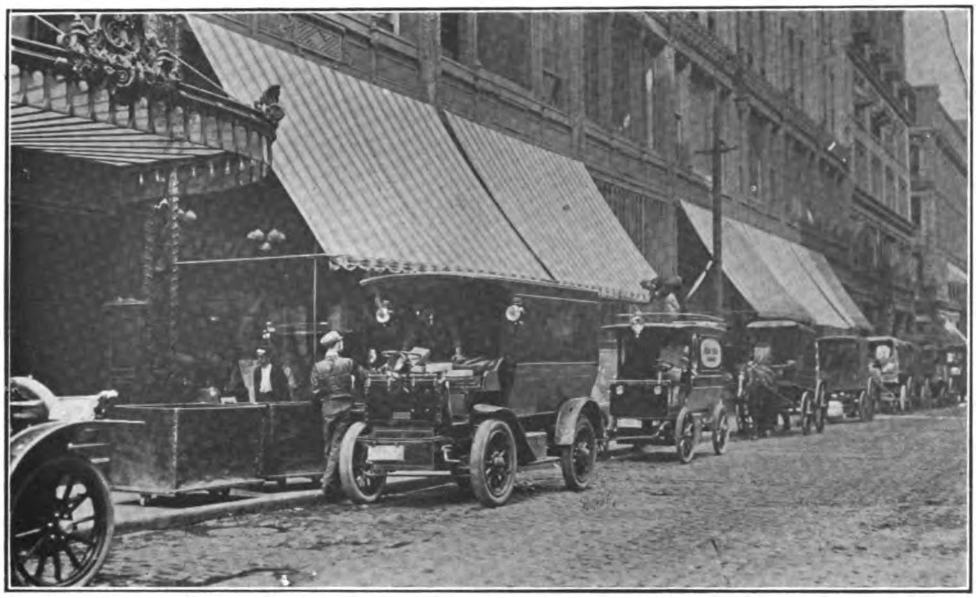
Taking as an example the store or business house that maintains delivery equipment, there is a limit to the area in which this service is practical, and beyond this it is necessary to send purchases by freight, by general express companies, by the local express companies, or by mail. In some commercial centres the street or highway railroads have developed special transportation service that is incidental to passenger traffic, but is advantageous because of its quick deliveries. This form of service is not available in all localities, but wherever it has been inaugurated it has been given excellent patronage because of the cheaper rates and the fact that it is competitive with other carriers.

Parcel Post Service.

There are express companies that specialize in transportation between different points, generally two cities, which will afford better rates for goods than will the general express companies, and these frequently develop substantial patronage, and it is often practical to have equally as fast service from such concerns. In addition to this is the parcel post branch of the postal service, the charges for which are more carefully graduated as to mileage and weight than are those of the corporations or private services. The parcel post package is delivered at the postoffice, it is dispatched on a fast train, it is sent out with the regular delivery at the office where received, and it is handled with the same care that is given to any other form of mail. The advantage of the parcel post is evident, but there are limitations as to weights and sizes that will be accepted. The packages sent by parcel post are generally paid or charged sales, but the government service will give the same attention as the express company, making collection and return of the money in the event of C. O. D. or goods sent on approval. This fact makes the usefulness of the parcel post service to the business man but slightly different in character than that afforded by the express companies. There are advantages obtaining with each form of service that are not possessed by both, and under certain conditions either may be especially desirable. Then there is a place in the mind of the business man for both express and parcel post service, and the governmental department has accomplished what is especially desirable for both seller and buyer, the termination of the monopoly of the express companies so far as the transportation of comparatively small packages is concerned. But beyond the weight and size of package carried by parcel post there has been no change other than a probable improvement of the corporation service.

Within the last 15 years motor vehicles have been used, but for more than a decade they had been regarded as experimental and of doubtful value, and it

Loading the Wagons of the Jordan, Marsh Company from the Sidewalk of Avon Street, the Packages Being Handled from the Carriers on the Narrow Walk.



Loading the Automobile Wagons at the Bedford Street Side of the Annex of the Jordan, Marsh Company, the Delivery Door Being Under the Last Awning Seen.

may be said that prior to 1910 there was but little known as to their actual economy. Even today the percentage of those who have accepted as established fact the real utility of the motor wagon or truck is very small, and when very careful estimate is made in differing localities it will be found that many who are now using such vehicles have no real knowledge of their economies. Not only this, there is no endeavor to learn methods or to adopt systems by which savings can be made, and there is no really beneficial result obtaining to the business world through the use of those now in service.

Road Conditions.

The horse has been the universal means of road transportation. Though mankind has known for ages that it is easier to walk in smooth and level ways than on rough paths, the disposition has been to neglect what will benefit all. Passing from man to the animal the same principle applies,but only within a generation has there been a systematical endeavor by the states to improve roads. City and town streets have been paved or graded because of the known economy, but despite the enormous cost of haulage comparatively little has been done as yet toward the betterment of the roads. The actual value of the improved road has been understood for centuries. The highways of Europe are decidedly better than those of America because they have been used for hundreds of years, and yet the main avenues of travel from the time of the Romans to today have been developed through military necessity rather than from the commercial possibilities. Commercialism has always accepted the line of least resistance and in this nation of magnificent distances railroads have been the solution of transportation when water was not available for inland communication.

In America civilization has followed the railroad, and in the greater part of the United States while the future has been planned for in communities developed within the last half century, and the city and towns streets are wide, these thoroughfares have not always been improved, while in the surrounding country roads have been developed from cart paths, and, aside from the main connecting highways, are seldom suited for economical traffic. There are those who will maintain that the statement as to roads cannot be well applied in the older sections of the country, but as a matter of fact the proportion of unimproved highway contiguous to cities of large proportions is astonishing when known.

The use of animals in transportation has been accepted without question. Animal vehicles were the alternative of manually moved carts, and horses were used because of their speed, though not as enduring or as powerful as bullocks. The main object sought was saving of time. With the limitation of the horses known the vehicles were improved. Next, some attention was given to roads, and in some instances these were made smooth, if not wide and level. Until the practical utility of the automobile for pleasure purposes was demonstrated the possibilities of road haulage were not considered, though experiments were

made by those who realized but little of the advantages of the machines.

Animals have been used for haulage because nothing better was available. This is applied from the viewpoint of practicality. No effort is made by the average business man to determine the actual cost of animal transportation. The faults and limitations of the horse are well enough known, but animals have been utilized without the same attention to expense that would be given to any other detail of business administration. Or perhaps it may be better said that animal vehicle transportation has been accepted as satisfactory and economical from the fact that this was seemingly sufficiently proven by its use by innumerable concerns.

Comparison of Expense.

Considering horse expense for a moment it can be stated that there is hardly an instance where the record, if kept, has been of work accomplished and the cost of a definite unit established. To illustrate: The record may show the daily cost of a given vehicle, it may give it for the week, the month or the year, but there is nothing that will indicate the exact price of a unit of work, either on the basis of mileage, tons carried, ton-miles, package or any other practical standard. Not only this, animals vary in capacity, and while it is not practical to show what each, or each vehicular unit, has done, it is reasonable to find an average. But instead of having information of this character the assumption is that daily cost of an animal vehicle is definite. Nothing could be further from the fact. It may be that the work is exceedingly variable and that the expense will differ widely from time to time, or it may be nearly uniform. But the work is computed on a basis of so much vehicle expense.

Until the need of comparison of animal and motor vehicle costs was realized this determination was satisfactory. But here the owner demands the expense of the motor and assumes that the daily basis will give him the required information. He understands that the motor has greater capacity and speed, but he has no facts relative to the cost for each unit transported. There is the difference of expense of the two forms of vehicle, but this should be proportioned. Only by so proportioning the cost can delivery expense be ascertained, and this will afford specific data, from which intelligent deductions may be made.

The lack of a definite measure for work (no matter what the standard may be so long as it will adequately represent the desired fact) makes necessary the comparison by daily cost, and this is misleading to even the expert. It is the custom in industry to measure production, and the merit of the method, system or means of producing is established by this measure. The logical value of transportation is represented by work, and the cost of this work demonstrates the economy of the vehicle used.

It is exceedingly difficult for the truck salesman to approach a business man with the general statement of motor vehicle efficiency and convince this man that he can economize, advertise and extend his patronage through the use of machines. The best informed sales-

ly influence others. Equality of service is not sufficient.

There are always lines of demarcation when economy alone is considered. The delivery of any business is variable and there is seldom an instance where the same volume of haulage is maintained. Not only that, there is the element of unproductive mileage of vehicles that must be considered. Were it possible to have the distribution from one end of a route to the other, the problem would be exceedingly simplified. This, however, is seldom practical. Considering economy solely, there is a limit to any area wherein delivery can be made, but the equipment is a material factor. To illustrate: If the saving is of time then the main consideration is speed, but if it is cost without reference to time, then the limit may be considerably extended for the same expense. Usually both time and cost are combined and this is the aspect from which delivery is regarded.

It might be put another way. If business depends upon delivery within a specified time a special vehicle or a special messenger may be considered, or possibly the regular service will suffice. If the third form named will meet requirements it is undoubtedly cheaper than either of the others. If, however, the delivery can be delayed until there is a sufficient volume to send it by a vehicle assigned to this particular work, or it can be carried by a service that specializes delivery in this section, the saving is apparent. People, however,

man may have his own ideas of the possibilities with vehicles as demonstrated in other conditions, but this does not mean that similar results can be realized in the particular case under consideration.

Factors That Determine Economy.

It is evident enough that volume of business transacted is a potent factor. The same laws that apply to business generally may be applied to delivery, and the store or shop or works that has large equipment generally has better facilities, system and organization, all of which contribute toward the economy of haulage. The expense of distribution in one locality cannot be paralleled in another, and the variance may be material. Conditions may be such that one could not expect to equal the showing in another city. The factors that have a bearing are numerous. They include first of all overhead expense, then administration, character of equipment, facilities for operating, capacity of employees, the topography of the community, the condition of the streets, the wages paid, the quality of upkeep and maintenance, the prices for supplies, and the requirements of the service.

But beyond all this is the demand of the people, which is generally resultant from competition. A service that might be adequate and meet with every requirement in one city will be decidedly insufficient in another. Those who desire to attract custom have policies to maintain with reference to prices, qualities, delivery and attention. These will natural-

The Main Delivery Door of the Shipping Department of the Store of R. H. White & Co., in Norfolk Place, Close to Harrison Avenue.

that enter into the problem, and before the requirements of the individual business can be intelligently considered it is first necessary to understand the locality conditions. There are admirable examples of transportation organizations existing in comparatively small establishments, and these have been developed with reference to the economies within the control of those administrating them, but not to the realization of the greatest saving. To save from every possible viewpoint might mean the utilization of some of the other services available, but this could only be accomplished at the expense of the convenience of the patron.

have become accustomed to demanding that a purchase be delivered as quickly as is practicable after it has been sold, and this impels the maintenance of a service that will be sufficient to meet these demands. In other words the general policy of the business house today is to send out at frequent intervals the deliveries for any one locality, and at speed to satisfy the most exacting. Perhaps it may be best put by saying that competition forced a fast and necessarily expensive delivery to serve those who were first a small proportion of the patronage, and as the advantage of the quick delivery was realized there was no reason why it should be rejected.

Service Must Be Paid For.

Turning to fundamentals for an instant, it is unquestioned that this service must be paid for. Without doubt all the costs are added to the stock prices, and theoretically each dollar's worth of stock sold must pay its proportion of the delivery expense. There is, of course, more or less of the sales taken from the stores by the customers, but while this varies exceedingly it can be said that the ratio of customers that carry home their purchases is constantly growing smaller. In the accounting the total cost of the delivery expense is charged against receipts. But the customers, for the convenience of delivery, are willing to pay, and the expense is dependent upon many factors.

The general principle of delivery appears simple. In theory it is merely removing commodities from the one point to another by the cheapest and most practical manner, but there are innumerable factors

Few have even a vague knowledge of the ramifications of the general subject of transportation. The first city to which attention has been directed is Boston, and this because it offers one of the most complex problems of the nation so far as haulage is concerned. The investigations were directed toward every available form of common carrier that can be employed, and while department stores were the basis for inquiry the survey naturally was to all forms of industry and commerce in which road vehicles are used. Just what proportion of the transportation facilities can be motorized is uncertain, for much will depend upon the attitude of the owners or those controlling them. It is certain, however, that there are innumerable opportunities for the use of motor vehicles because of the peculiar and unusual character of service demanded. The interests of the different transportation companies impel the improvement of service when this is possible, and competition demands that there be the greatest measure of economy it is possible to secure.

Harrison Avenue Extension at the Rear of the Store of R. H. White & Co., the Main Receiving Entrance Being Under the Awning, Partly Concealed by the Truck.

BOSTON'S EXPRESS AND STORE SERVICES.

EVERY locality has its own peculiar conditions with reference to transportation, a statement that applies equally well to the service afforded by railroads or steamers for freight, by express companies doing general or sectional distribution, by those doing similar work in several communities, by those confined to a single community, and by the individual business firms.

These conditions are the result of business requirements, without question, but the services have been developed without consideration of the possibilities of economy. Business competition has prompted promotion of haulage concerns, each having at inception a specific work, and it is but natural that those promoting them have sought to extend the scope of their activities and the volume of transactions. As the communities have increased demands have impelled the establishment of service to meet existing needs, and these have been developed to widely differing proportions.

Winter Place, Looking from the Steps of the Building at the End Toward Winter Street, Where the Shipping and Receiving of the Shepard-Norwell Company Is Done.

Boston is the commercial centre of New England and it is the second largest shipping port of the nation. It is surrounded by a large number of cities and towns, from which its business is drawn, and it is, broadly speaking, the purchasing place for a population that can be estimated as close to 1,500,000, while within a radius of 60 miles are no less than 3,500,000 people.

The Business District.

Boston attracts to its markets people from a much larger area than is included in this 60-mile circle, and this statement can be generally applied to every need aside from fuel, food and raw materials for manufacturing. Because of obvious reasons business houses have been established in the section of the city close to the water front and the railroad terminals, and, as is usually the case, those dealing with a special product are close together. The wholesale district of the city is that part first settled, when streets were originally paths and then roads, there being no thought given by the Colonists to the requirements of the centuries to come.

The retail stores and shops have been for a century located in Washington and Tremont streets and the thoroughfares between them, and in this section of the city these establishments are so well entrenched that there is little probability that they will be removed, though experience would justify the supposition that there would be a general retreat of the retail district before the demands of the wholesale division of business. This has been the inevitable result in other cities, and there would appear to be no reason to expect anything else in Boston were it not for the fact that passenger transportation systems and facilities have been developed with a view of meeting the requirements of the people with reference to the present locations, and change could only be made at enormous cost. In fact the expense of a change would be practically prohibitive.

Boston from the viewpoint of the transportation student is peculiarly located. The water front is utilized in every sense and the shipping requirements have impelled the building of two stations as terminals for the New Haven and New York Central lines, which control all the railroads centring in the city, and the freight yards are adjacent to the passenger stations. It is desirable for the retail business men to be located as closely as is practical to these stations, and as it now is the retail stores are comparatively near to them. This statement is applied especially to the department stores, where immense volumes of business are transacted annually, and to which people are drawn from all parts of New England. While it is true that there are thousands of stores and shops, and the business has extended along the main thoroughfares in every direction, these are more or less dependent upon locality patronage. There is also a class of specialty shops and exclusive stores, where the custom is limited because of the character of goods carried. It is no exaggeration to say that there are more of such specialized goods in Boston than in any other city of similar or even larger proportions in America, for Boston is an extremely wealthy community and the people demand a greater ratio of special products.

The City Proper.

The old part of the city in which the streets are narrow and where there is very generally congestion

Sidewalk Elevator in Winter Place on Which Is Carried Practically All the Goods Shipped or Received at the Store of the Shepard-Norwell Company.

stretch from the Quincy line to the western Brighton line is about 9.5 miles. Brookline, which is said to be the wealthiest town in the world, is nearly surrounded by Boston, its people having rejected all proposals for annexation to Boston because of the difference in taxation.

The Metropolitan Section.

What is regarded as the metropolitan section or district is practically the area contained within the 10-mile circle, and this includes the cities of Cambridge, Chelsea, Everett, Lynn, Malden, Melrose, Quincy, Somerville and Waltham, though Lynn is not generally included in this designation, and the towns of Arlington, Belmont, Braintree, Brookline, Canton, Dedham, Lexington, Medford, Milton, Newton, Needham, Revere, Saugus, Stoneham, Wakefield, Watertown and Winchester. It will be noted, however, that this circle does not take in all of these towns and in several instances the greater part is outside of the circle. In all there are 27 towns and cities within or touched by this circle.

Outside of this circle and included in the same manner in a radius of 15 miles from Boston Common is the city of Salem and the towns of Bedford, Burlington, Cohasset, Danvers, Dover, Hingham, Lincoln, Lynnfield, Marblehead, Natick, Norwood, Peabody, Randolph, Reading, Swampscott, Wayland, Westwood, Wellesley, Weymouth, Weston and Wilmington. The map also shows outside of this 15-mile circle the city of Beverly and the towns of Acton, Billerica, Carlisle, Concord, Framingham, Holliston, Medfield, Scituate, Sherborn and Sudbury, but these are not all of the

of traffic, may be said to be east of Charles, Berkeley and Pleasant streets, and Broadway extension. This does not include some portions of South Boston, East Boston and Charlestown. West and South of this area the streets are not only much wider and better laid out, but there is not the extreme use made of them. In the older portions of Boston are all the wholesale and all of the large retail stores. There is in the West End, so-called, and the section along the water front, a considerable foreign population, where there is comparatively little demand for delivery of goods, but aside from this in all of Boston and all of the towns and cities surrounding it there is need of delivery that is more exacting than in any other city in America, if not in the world.

This statement will, no doubt, be debated by those who believe that the demands made upon them are excessive, and that they are required to insure to their patrons service that will satisfy them, but when the conditions in other cities are carefully analyzed it will be found that the Bostonians have been educated to expect from the business houses services that cannot be equalled in the world.

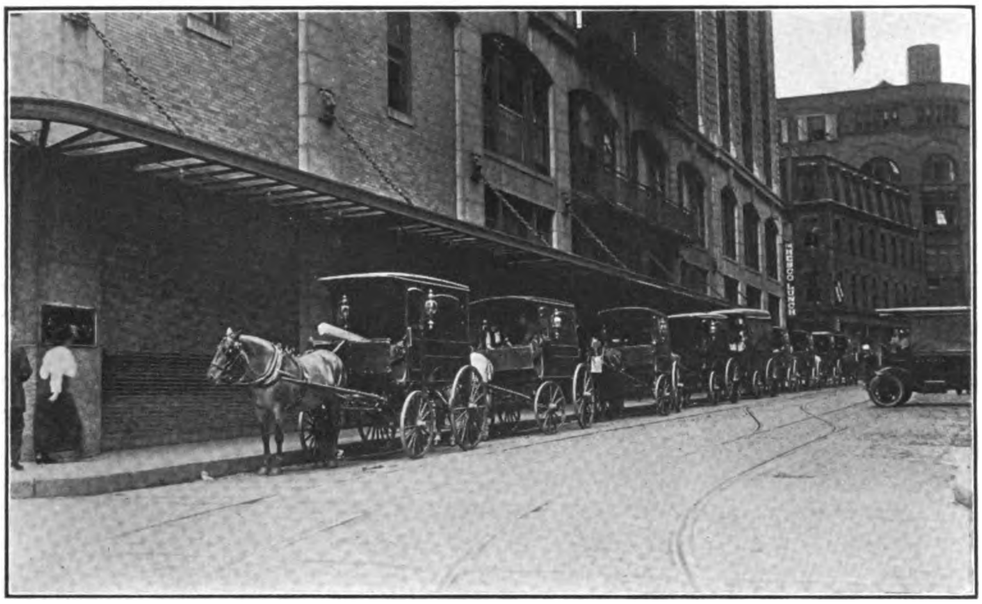
Boston, as will be noted from an accompanying map, which shows in outline the location of 12 cities and 49 towns that surround it and the approximate distances by circles indicating mile zones, is practically 11 miles long, extending from the mouth of the Charles river inland, and including Charlestown and East Boston on the north of the Charles and the harbor the length is nearly 14 miles. The greatest width at the southwest or inland end of the city is six miles, but the

Receiving Entrance of the Store of the Henry Siegel Company at Essex Street and Harrison Avenue Extension, from Which Some Stock Is Also Shipped.

municipalities included within the 20-mile circle. Less than half the number in this circle are shown, so it can be stated that within this radius of 20 miles are no less than 75 cities and towns. The population is approximately 2,000,000 people, and for this number Boston is the regular place of purchasing.

The Transportation Facilities.

These towns and cities are the places of residence of many thousands who do business or are employed in Boston, and the demands of these people have brought about generally adequate transportation, either by steam or trolley railroads. In these towns and cities are substantial and progressive industries, some of them of very large proportions. These communities patronize the local stores for household supplies and for more or less of other necessaries, but a considerable part of the buying is done in Boston. Boston is the distributing point from which a large proportion of the supplies of stock for these stores and factories is sent out, and it is again the collecting point from which a large part of the manufactured products is shipped.



Delivery Wagons of the Henry Siegel Company in Harrison Avenue Extension—the Main Delivery of Parcels Is from the Entrance Under the Fire Escape.

From Boston in every direction inland or along the coast radiate steam and electric railroads and there are numerous steamboat lines that are operated a part or the whole of the year. There are direct water lines between Boston and the principal cities of the coast, and, of course, the steamship lines that afford regular service between the large ports of the different countries of the world. Large volumes of raw material of all kinds, fuel, and the like, are received at Boston and distributed from that city by rail lines. New England is largely given over to manufacturing, and agriculture is incidental at best. The logical distribution of the manufactures is throughout the country and this means that the great bulk of all products is sent West, and the receipts are received from the West and South. Thus in the natural course of events there is the shipment into and out of New England, this affording carriage two ways, which insures to the railroads and the big transportation companies an unusually large volume of business.

But it is with the inter-town and inter-city transportation that the highway vehicle has its special value. Just what radius of delivery is most economical depends upon circumstances and conditions. In the absence of railroad competition and the high rates charged for freight is the hope for the utilization of motor wagons and trucks, although there is another element that must be considered, and that is the express companies. There are those who will maintain that the individual service is the most economical, but the volume of haulage is a decidedly important factor. It is this exceedingly large work that has given Boston what can be regarded as the equal of any local transportation of the country, if it is not the best in the world. There is no better demonstration of the value of competition and monopoly than is to be found in Boston, for at the one hand is the remarkable delivery service of the expresses and the stores, and at the other is the excessive high rates charged for freights by the railroads. Not only this, but it is common knowledge that it costs more to send freight out of New England than it does to bring an equal volume of commodities or raw material into these states.

The Department Stores.

In considering vehicle transportation in Boston the department stores have been made the basis of the investigation from the fact that the demands of the people have been with these concerns unusually exacting and the radius of delivery is unrestricted within New England. There are a half dozen companies that may be regarded as conducting large establishments, and there are a considerable number of others that will be placed in the same classification, though transacting less volume of business. Of these the largest is that of the Jordan, Marsh Company, which is known throughout the country as one of the representative firms of the nation, and there are others that are hardly less known. These include the William Filene's Sons Company, the Houghton & Dutton Company, R. H. White & Co., the Shepard, Norwell Company and the Henry Siegel Company. Of these the Jordan, Marsh Company is the oldest and next is the Shepard, Norwell Company, the Houghton & Dutton Company, R. H. White & Co., the William Filene's Sons Company and the Henry Siegel Company, the last named being established about eight years ago.

Of these the store of the Houghton & Dutton Company is maintained to be the original department store

Sidewalk of Harrison Avenue Extension, Looking from Hayward Place Toward Essex Street, Where the Packages Are Loaded by the Wagons of the Henry Siegel Company.

in America, it being established in 1872, one of the firm having been associated with R. H. Macy in New York and organizing the firm of Houghton & Dutton, which departmentalized its store, and from which origin has developed the thousands of establishments conducted along similar lines in this country and, perhaps, abroad. The Houghton & Dutton Company's store is at Tremont, Beacon and Ashburton streets, at the east base of the historic Beacon Hill, and directly opposite the famed old King's Chapel. The store of the Shepard, Norwell Company is between Washington and Tremont streets and extends from Temple street to Winter street, with Winter place, a narrow court, along one side. This court extends about half through the block and there is a foot passage through a building by which pedestrians may go from Winter street to Temple street.

The store of the William Filene's Sons Company is at Washington, Summer and Hawley streets, this being occupied in September of last year. The Jordan, Marsh Company's store occupies two large buildings, the old structure having frontage on Washington and Avon streets, one section of which extends from Avon to Summer street; the other building occupies the eastern half of the block between Avon and Bedford streets, with Chauncey street on the east. The store of R. H. White & Co. is in the block surrounded by Washington and Bedford streets, Harrison avenue extension and Norfolk place. The Henry Siegel Company occupies the building covering the block bounded by Washington and Essex streets, Harrison avenue extension and Hayward place.

The distance between the Filene, Jordan, Marsh and White stores is that of a comparatively narrow street, and a short block is between this group and the Siegel store. There is perhaps 300 yards between Summer and Essex streets, and there is probably 350 yards between Filene's and the store of the Houghton & Dutton Company, with that of the Shepard, Norwell Company not more than 100 yards distant from Filene's. Boston Common, the State House, the postoffice and the city hall are all regarded as the point from which distances are computed, but all are sufficiently near each other to make but little difference in the result, no matter which is accepted.

Topography of Boston.

Boston, as will be noted from the accompanying map, is irregular in form and the old portion is between the Charles river and what is known as South Bay, there being an arm of the sea connecting this with the harbor that is known as Fort Point Channel. East of this section is South Boston. South of South Boston is Dorchester, and south of the old city is that section known as Roxbury. Southwest is Jamaica Plain, while west, connected by a narrow strip along the Charles river, is Brighton. There will be references made to localities that do not appear on the two maps that are included and these are designations of different parts of the towns or cities. Allston, for instance, is a section of Brighton. There are innumerable names that are thus applied and which have no significance aside from the fact that they

Receiving and Shipping Doorway of the Henry Siegel Company in Hayward Place, Where the Furniture Is Shipped and the Large Bulky Goods Are Received.

more definitely locate some parts of these suburbs.

Many years ago when the suburbs of Boston were being developed and the people of these sections wanted delivery of purchases there was no especial stress placed upon time, so the thrifty Boston merchants limited the area in which this service was given to what was then known as the "city," a designation which has been accepted and has been retained since that time. As the city has increased and some of the towns were annexed the lines of demarcation first established were preserved, and today the "city" as defined by those engaged in transportation is that part of Boston bounded by the Charles river, the water front, Fort Point channel and by an irregular line extending in a southerly and easterly direction from the Cottage Farm bridge at the Charles river, Borland street, Audubon road, the Back Bay Fens, the Boston & Albany tracks, Hemenway street and Lenox and East Lenox streets. This area is much larger than that originally defined, for less than a score of years ago if a delivery was made to Massachusetts avenue it was regarded as being well into the country. But gradually the service was extended to the east end of Brookline and to some sections a short distance beyond Massachusetts avenue.

One of the 21 Offices and Receiving Stations of the General Express Company in Boston, at 105 Arch Street, a Clearing House for Nearly 100 Common Carriers.

Traffic Regulations.

The streets of Boston east and southeast of the historic Common are very narrow, the roadways frequently being not more than 20 feet, with sidewalks perhaps five feet width, while there are innumerable alleys with room for a single vehicle between walks just wide enough for a single person. Some streets were made wider following the fire of 1872, but considering the volume of traffic there is none that is adequate for the requirements. For this reason traffic regulations make many of the streets one way only, and vehicles are not permitted to remain for more than five minutes unattended and 20 minutes attended, and in some streets they can simply stop long enough for passengers to alight or enter. The street commissioners having charge of the enforcement of the traffic regulations are seriously considering the making of a provision that all heavy vehicles shall be denied the use of Washington street between the hours of 9 in the morning and 5 in the afternoon. The effect of the ordinance has been to keep the streets clear of standing wagons and machines, but the rule is more strictly enforced with regard to vehicles used for pleasure. Thus far no real burden has fallen upon those doing business, although the enforcement of the regulation would undoubtedly work many hardships. It will be understood that the rigid enforcement of the ordinance would mean the loading and unloading of much freight at night and a complete revolution of the methods now the vogue. While this result will undoubtedly come there is no reason to apprehend any radical action that will seriously handicap the business men.

But the fact remains that the congestion has constantly increased in the streets, that the traffic regulations require longer time for doing a work because of the need of observing them, and that the only possibility of relief is in giving over the highways in the wholesale and retail districts wholly to business. When the limitations have been reached there will be no other alternative than to increase the number of hours in which work may be done.

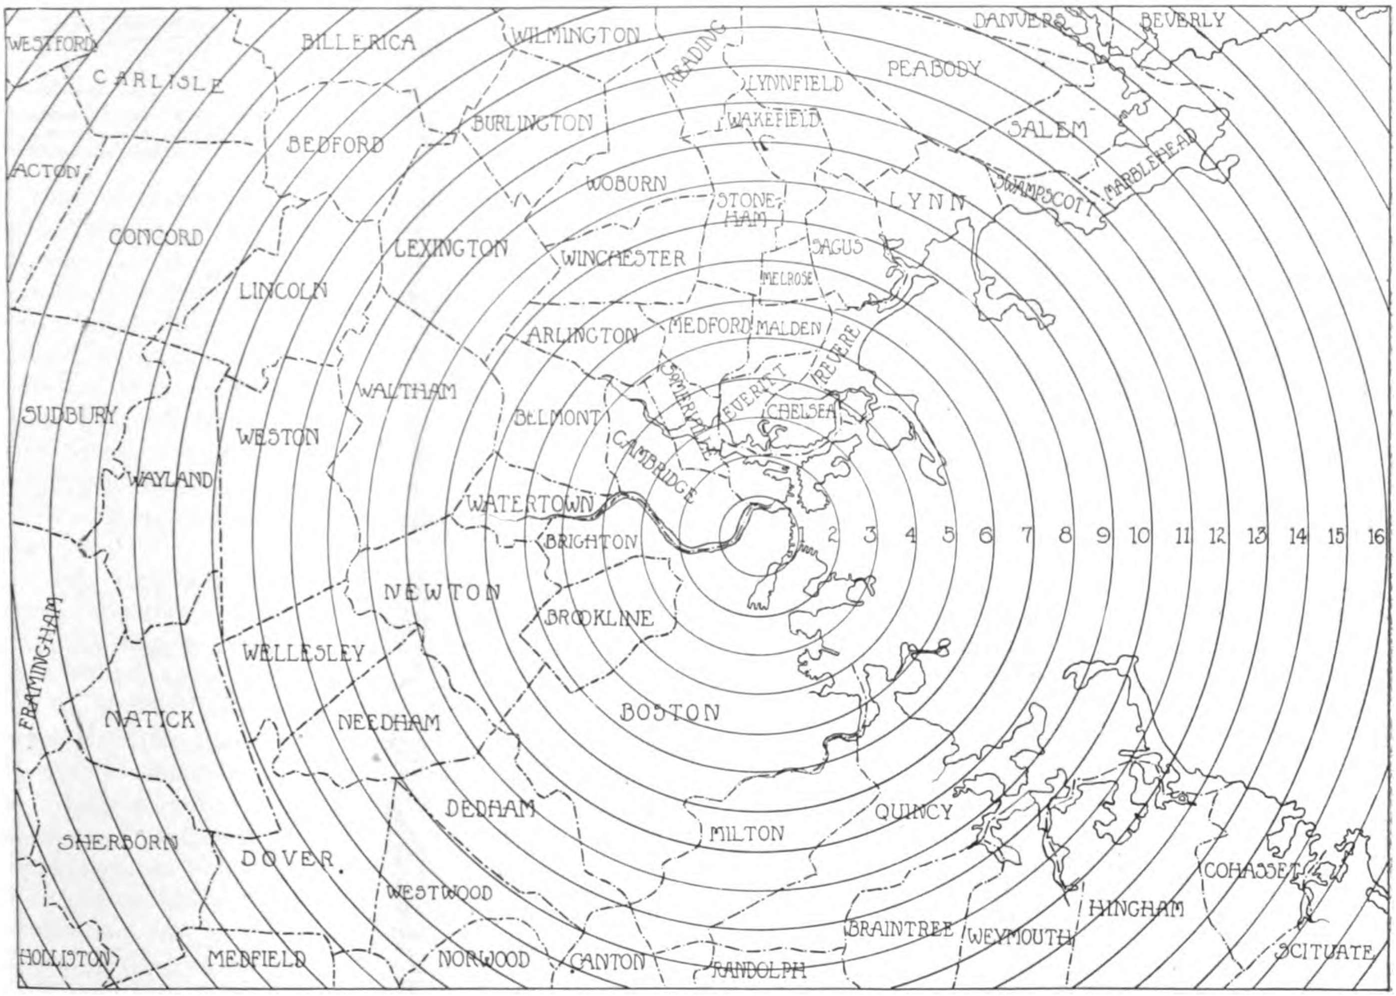
Provisions for Delivery.

The delivery of the six stores that are specifically dealt with in this article, outside of Boston and its suburban district, has practically the same basis in that any purchase valued at $1 will be delivered free anywhere within the State of Massachusetts, household furnishings excepted, to any express office, freight office or postoffice, and all purchases valued at $5 or more will be delivered to any express office, freight office or postoffice, and all purchases valued at $5 or more will be delivered to any express office, freight station or postoffice in New England. The companies reserve the right, however, to ship by express, freight or mail, as may be most convenient. If the shipment is made by freight, however, this means delivery at the freight station and not at the home of the purchaser. Thus it will be seen that any purchaser is on exactly the same basis, no matter where the place of delivery. The area covered by this form of delivery is much larger than is included in any metropolitan store, and it is probable that this service is not excelled anywhere in the world.

The delivery in Boston and the suburbs of the city, however, is an entirely different proposition, and while it is free the manner of handling the purchases dif-

fers decidedly. The furthest that delivery is made by the equipment of any store is approximately within a 10-mile radius from the stores, and a glance at the map showing the mile zones will give a very comprehensive idea of the area covered. Each store has its own system and methods of delivery, developed through experience and from knowledge of the needs of the customers, but when it is stated that the service afforded Bostonians is better than anywhere else in America the statement is made advisedly.

With rare exceptions, within the area of delivery, the customers can expect to have the goods bought up to the time of closing the stores delivered the same evening, and this is true if the customer lives within a radius of 20 miles. The outside delivery, however, is made by other agencies. But the organization is entirely within the control of the shipping departments and there is absolute certainty that the deliveries will be made.



Map of Boston and Suburbs, with Towns and Cities Included in the Mile Zones from the Boston Common, Recognized as the Civic Centre, and Close to the Principal Points of Distribution.

Delivery Equipment Available.

The combined delivery equipment of the stores consists of 61 automobiles and about 425 horses, but in addition to this there are innumerable delivery or express companies that cover the different communities which are regularly or occasionally used. There are in all 367 different express services centred in Boston, of which four are general and make deliveries throughout the country, 15 give a specific service between New England points and 343 are or may be classified as city or suburban. There are, in addition to these services, many others that do a regular business of haulage between different sections or places, as well as a considerable number that is engaged in general transportation, taking any work that may be required, for a single trip or for definite or indefinite periods.

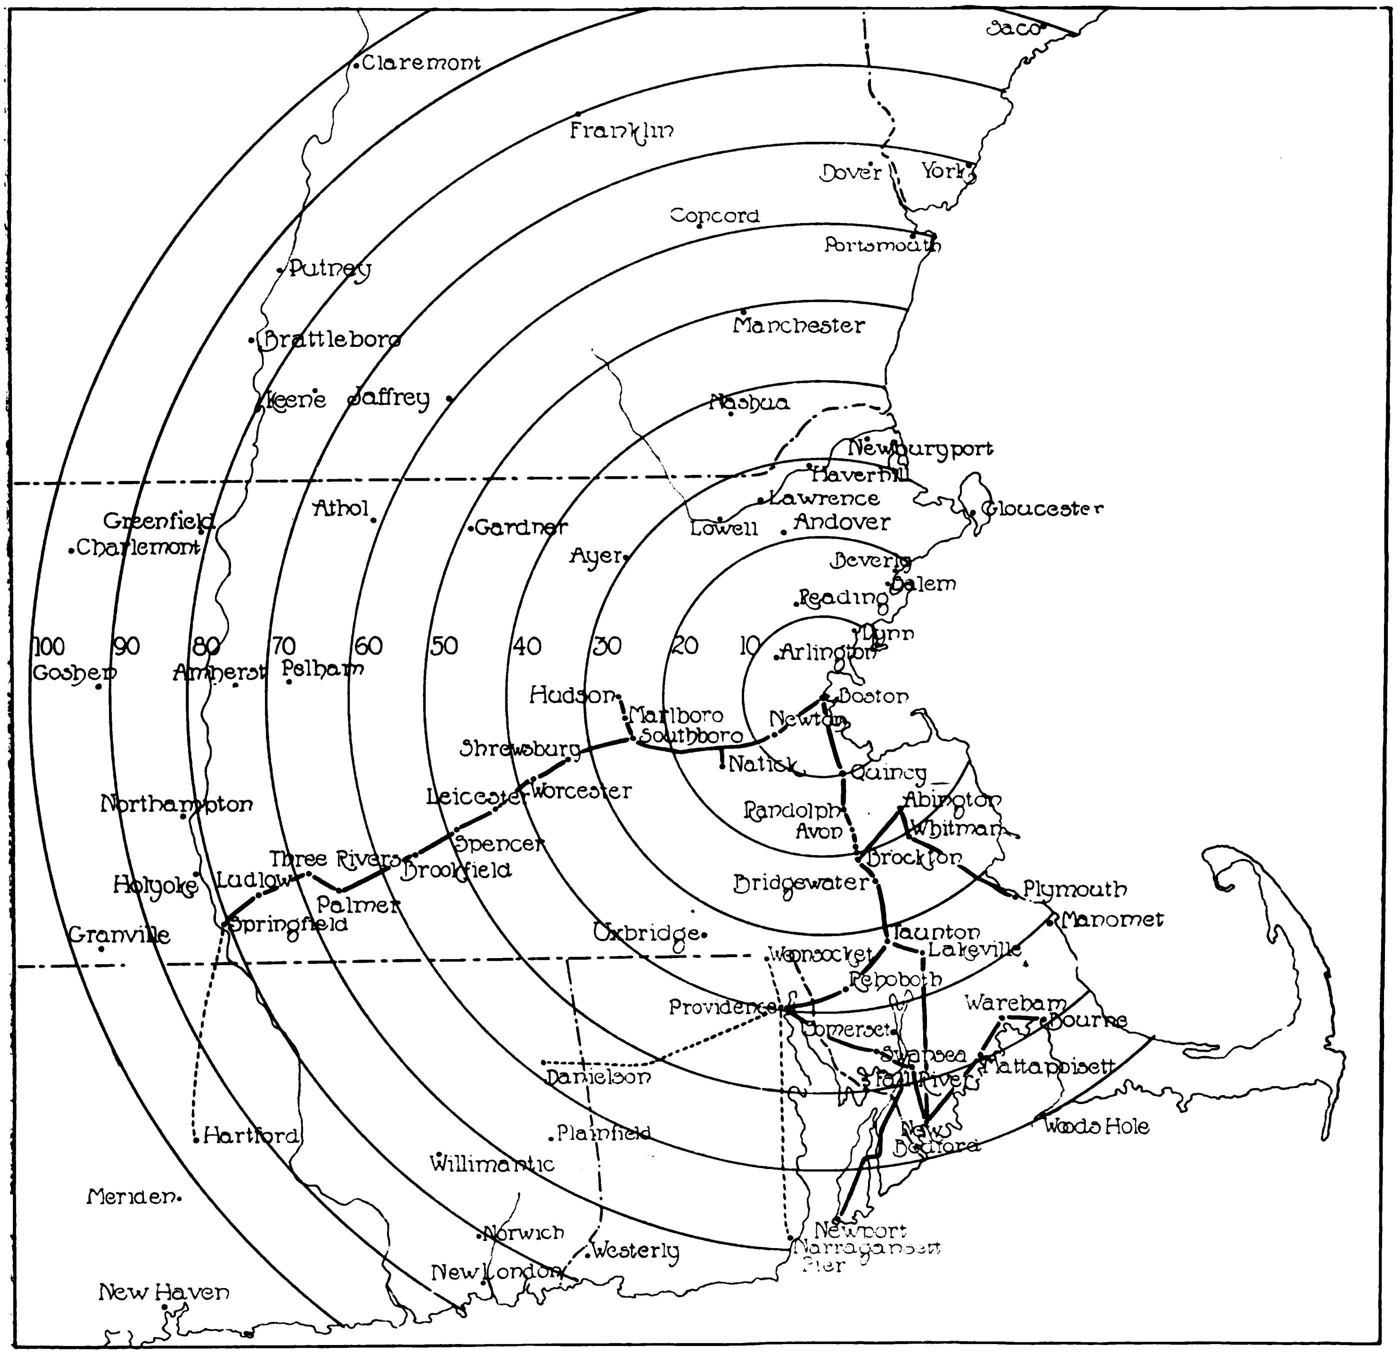
Regarding these different express companies for a moment. There is an organization of these concerns known as the League of Express Companies, which may be said to be local to Boston, maintaining its office there. Membership in this is held by the four general express companies, by about half of the concerns doing a New England business, and the remainder of the listed members consists of those who do local or suburban transportation. The league is known in Boston and the different communities where it has representation and the impression obtaining may be said generally to be that a thoroughly satisfactory service can be secured from a league company.

Whether or not there is a greater degree of responsibility attached to a service given by a league company and whether or not there is a larger measure of satisfaction insured may be debated by those who desire, but there is undoubtedly importance placed upon membership and the prestige afforded is appreciated

if not valued. The league is controlled by a directorate and this body passes upon all applications for membership. There is assumedly a disposition to limit the number of members, and frequently petitions are refused. By some the league is considered to be a close corporation in its attitude toward admitting new members. The benefits are said to be the exchange of information concerning general and specific subjects, co-operation so far as policies are concerned, agreements as to rates, services, exchange of business, and the exercise of such influences as will benefit members specifically. But it will be seen that the league companies are the minority so far as number of concerns doing business in Boston and vicinity. Of the 367 companies there are the four general companies, 15 concerns doing a New England business, two doing an exclusive freight business and three handling parcels, the parcel deliveries making a specialty of serving stores.

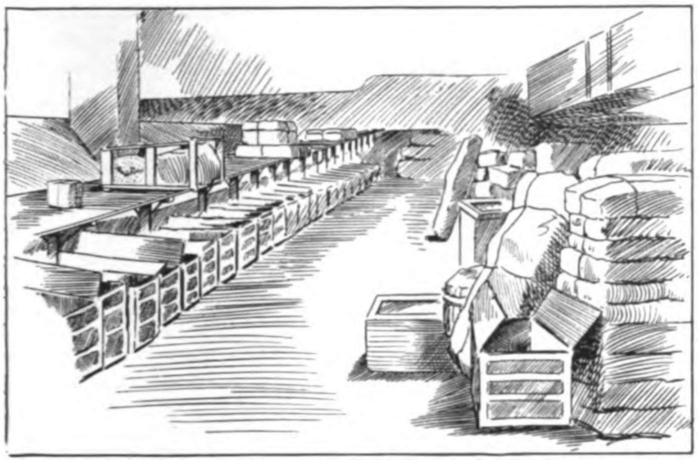
Clearing House Methods.

The General Express Company is unique in that it does not own a vehicle and yet it has 21 offices in the business section of the city. It is practically a clearing house for a considerable number of companies—more than 100 in all probability—and each station gives exactly the same service. For a stated amount a company is furnished with a small drawer in a large file case, and in some instances a compartment in a tier of bins. Packages may be left at this station for the subscriber and these are placed in the bin assigned. Call orders are received by the operator of the branch telephone exchange and these are written out and placed in the subscriber's drawer. Any information



Map Showing the Principal Commercial Centres and Their Relative Distances from Boston by 10-Mile Zones—Within the 60-Mile Circle Are 4,000,000 People, and Within the 100-Mile Circle 5,000,000—The Black and Dotted Lines Show the Electric Express and Connecting Lines and the Points Reached by Them.

relative to the subscriber's service is furnished inquirers. Calls are made at stated hours and collections made by the subscribers. This service may be likened



Section of the Shipping Room of the Filene Store, Showing Arrangement of Carriers and Stand for Large Bundles in the Express Section.

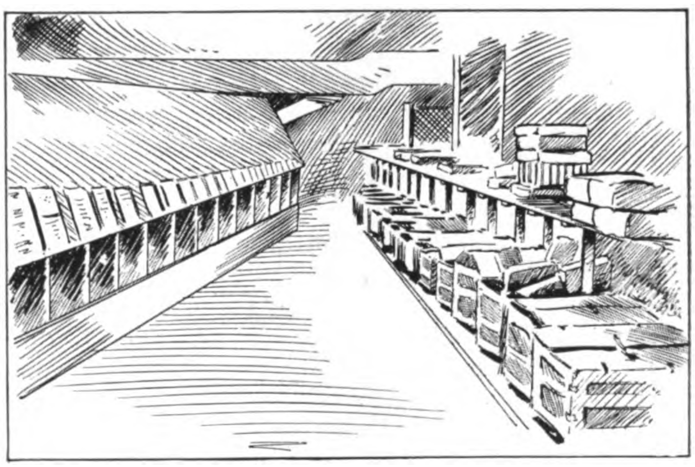
to that of a central office for each express company subscribing, and makes it possible for them to extend transient business, for this does not affect their regular customers, although it is beneficial in that it provides for an emergency service without requiring additional equipment. Not only this, but the expense on the basis stated is comparatively small for each subscriber. These offices are open from early morning until well after business hours. During the day packages and freight are received and so far as possible they are sent out the same day unless received after the last call hour.

Once each quarter a list of all the recognized express companies is published, this designating the company, its stations and the hours for calling, and this list is sold to those who desire it. It contains in addition to alphabetically arranged listing of the companies a similarly prepared list of all the towns and cities, and in some instances the postoffices or village designations with the names of each company by which that particular point may be served. This applies throughout New England. Thus to reach a given place the company that can be used can be instantly ascertained, and by reference to the companies the locations of the stations in the city and the hours of collecting may be learned. In such lists the members of the league are designated.

How Sections Are Served.

Many of the express companies afford regular service to stores and manufacturers at both terminals and accept such other business as may be offered, and the value of the clearing house method is evident when transient haulage is considered. As may be assumed, it is necessary to collect and distribute at either end of the haul and the location of the receiving stations does not by any means represent the area covered by each company. It must not be understood that there is a limited service unless in the event of some remote locality, and on this list from three to 24 different companies can be found that will make delivery in a given section. This does not mean that this applies to towns and cities only. For instance, Allston, Ashmont, Back Bay, Brighton, Charlestown, Dorchester, East Boston, Hyde Park, Jamaica Plain, Readville, Roslindale, Roxbury, South Boston, South End and Wollaston are all in the city of Boston, and from five companies in the case of Hyde Park and Roslindale to 20 in the case of Roxbury are available. Taking the immediate suburbs of Boston, 19 different companies serve Cambridgeport, 24 Cambridge, 18 Somerville, 14 Malden, 14 North Cambridge, 24 East Cambridge, 13 Watertown, 13 Quincy, 11 Revere, five Arlington, five Arlington Heights, six Brookline, 13 Chelsea, eight Everett, eight Lynn, eight Medford, five Peabody, seven Waltham, six Winthrop, five Belmont, three Hingham, three Wellesley, to say nothing of some communities like Newton, for instance, where there are six different sections each served from five to eight companies, there being no less than 16 serving the city.

Where there are so many different concerns doing the same business and covering the same areas there is enormous duplication of service, but it is also evident that the competition that has been developed is especially advantageous for the people. But this does not represent the possibilities, for most of the companies will deliver in practically any part of the city and suburbs where the work justifies and besides there are numerous store deliveries that serve the same sections. Of course it is only the store of large proportions that would undertake to make delivery within the 10-mile radius from the centre of Boston, but there are hundreds of smaller establishments that deliver within this area as well as a very heavy wholesale distribution. It would be impossible to estimate the volume of haulage by these different comapnies, and it should be understood that these do not represent all of the transportation. There is one haulage contractor in Boston who owns close to 400 horses, and there are many others who have what may be regarded as large equipment. There are numerous concerns that specialize

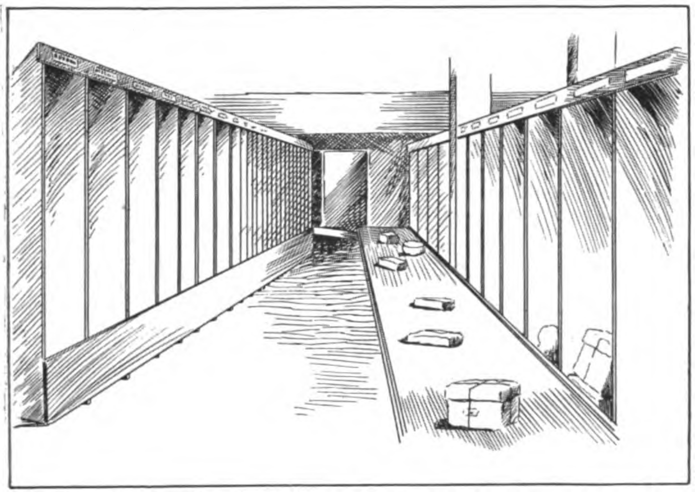


Part of the Combination Bin and Desk Construction and the Package Carriers in Another Section of the Express Division of the Filene Store.

in general trucking and heavy transportation.

Each company of importance has affiliation with other companies for the transfer of packages and

goods, so that one making a collection in Dorchester, for instance, may deliver a package to another having service in Lynn or Salem, and the price paid is divided



Belt Conveyor Between the Two Series of Bins, Those at Right for the Store Service, and at Left for the Express Service, the "Charge" Packages Being Carried to the Belt Shown at the Background—In the Filene Store Shipping Room.

by the two according to the rate established in the contract between them. Contracts are the rule for such transfer service and rates are based on weight, although bulk may be a factor under some circumstances. But this transfer may be effective if the shipper wanted to send a package express to Keene, N. H., or to Newport, R. I., and if there should be need of making a second transfer this is provided for as above stated.

Wherever possible contracts are made to do work and these are for a price that may be considerably lower than that charged for transient service. In other words, a constant volume of business can be done for less price than an indefinite work. There is not only competition between the companies serving specific localities, but these companies are also competing with the Adams, National and American companies, all of which have many local offices. When it comes to general distribution the freight service of the railroads and the general express companies have the greatest number of representatives, but for some cities and towns the smaller companies can make better rates and give equally good if not superior results. This is true of shipments that are made to points several hundred miles distant.

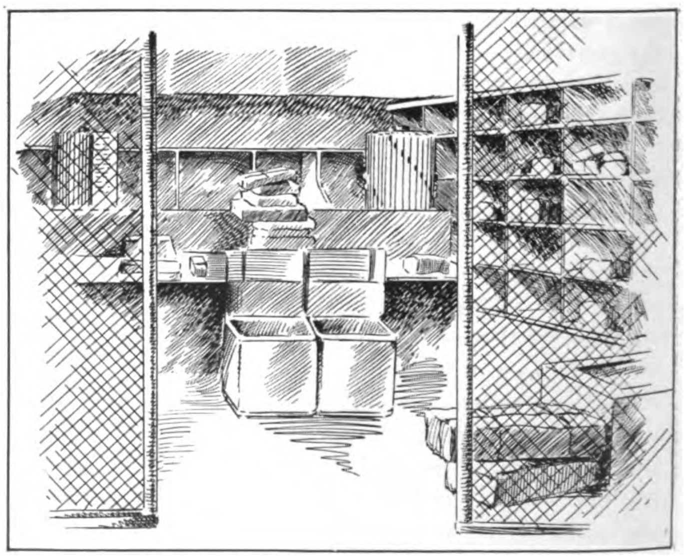
Motorized Equipment.

Aside from the American Express Company, which has 28 electric and six gasoline motor delivery wagons, and the National Express Company, which has 12 electrics, there is but comparatively little motorized equipment. There are 15 different concerns that have the name of "auto express" and the assumption is that a part of the haulage is done with machines, but just how many are in constant service is uncertain. Some use motor wagons in pickup and transfer work, collecting and distributing in the city and taking the freights to the outward destination, where they are delivered by animal wagons. One company, Chase's Express, located in Brookline, has adopted this system with excellent results. The fact remains, however, that but few motor wagons are used by the 343 express companies. There are seemingly large possibilities in this direction.

In several instances express companies have attempted to use motor wagons without success, and some of these concerns have resumed the use of horses. Whether or not this is the result of inexperience or endeavor to continue horse methods cannot be stated, but there is no possibility of avoiding the fact that much of the collecting and many of the deliveries are made in the badly congested streets, where the superior speed of the motor cannot be realized, and it is also a fact that the conditions for loading the vehicles could hardly be worse. In no instance is there provision made for quick handling of the loads and waits are very frequent. As an example of this the illustration of the Arch street office of the General Express Company will show that the wagons are ranged along the sidewalk and the packages are taken from the station and loaded. The drivers arrange their loads to facilitate delivery, but this is done with the wagons idle. There are certain formalities to be complied with so far as records are concerned, and this must be done by the driver. Not only this, if the motor wagon has a helper the time of two men is lost, as well as that of the machine, and no activity at the point of delivery will completely compensate for this. The manner of garaging and the driving are two unknown factors, and both of these are very important.

Parcel Delivery Companies.

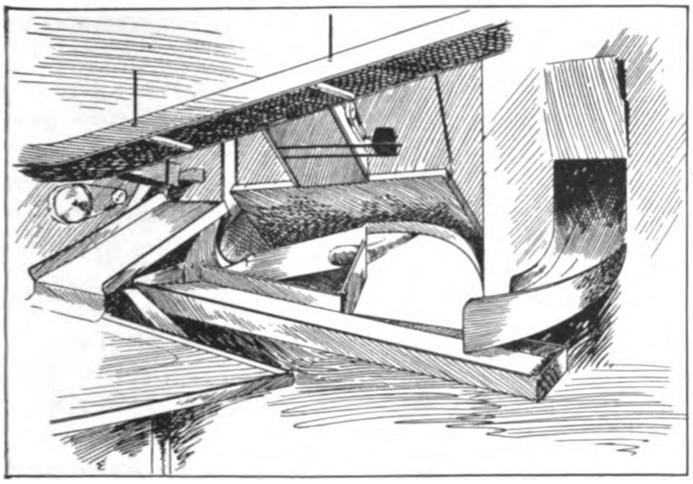
In addition to the express companies there are several parcel delivery companies that contract with the stores to make delivery. The oldest of these is the Boston Parcel Delivery Company, which was established in 1872 and has its central station in Stanhope street. The superintendent of the company is G. A. Pratt, who has had long experience with handling the



Charge Room of the Shipping Department of the Filene Store, Where the Packages Are Received, Examined, the Address and Account Verified and Records Made.

packages of many of the stores of Boston. The stable and the station are located in the same building and from 13 to 16 single-horse wagons are used daily. Ap-

proximately 1,000,000 packages are handled annually. The company makes delivery in what is known as the "city" and does not go outside of its recognized terri-



The Central Point of Collection in the Jordan, Marsh Company's Shipping Department, Whence the Packages Are Distributed to the Different Sorting Divisions.

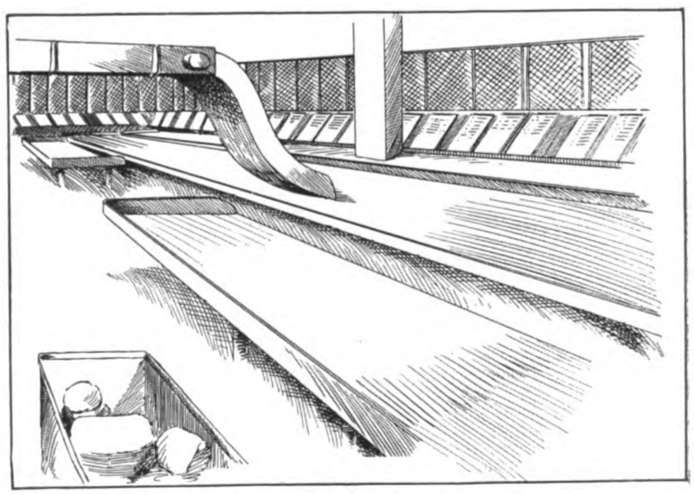
tory. It delivers the packages of the Filene and the Shepard, Norwell stores, and in addition serves a considerable number of other concerns. The method is to bring the packages from the stores to the station. They are then sorted for routes and are delivered from route wagons. Normally four deliveries are made daily. Collecting wagons make the rounds of the stores at stated intervals and collect the packages. The station is about a half-mile distant and the handling for the route wagons is accomplished very quickly. The packages that are to be sent to some of the express companies are sorted and these are later delivered to the receiving stations of the companies and are picked up. This is known as "transfer" work and from 15 to 20 per cent. of the packages handled are of this class.

Besides the regular places of call many special telephone calls are received from those doing comparatively small business, such as milliners, tailors and the like. Where the packages are numerous, contract is made for delivery and the price is five cents or six cents for a single package, according to the number handled, and the payment is made at regular intervals by the store. The tariff for a single package is 10 cents, but books of gummed stamps are sold to customers who do a small business, who can attach these to packages when delivered to the driver. This prepays the package. The price of the stamps by the book is $1.50 for 20. The sale of stamps minimizes the clerical work and this system is entirely satisfactory to the customer.

Packages will vary in size and weight and those weighing 15 pounds or less are given a "count" as a single, from 15 to 25 pounds two "counts," from 25 to 50 pounds three "counts" and more than 50 pounds four "counts," which means that the charge is twice, three or four times that of a single package. Boxes of considerable size, barrels, etc., are given four "counts." The great majority of the bundles are of the single "count" size, but large and heavy parcels are not desired because of the time required for handling them. The wagons are of the covered type with gratings at the sides and ends of the body to protect the goods from theft, with curtains that may be lowered in the event of storms. The crew of each is a driver and a boy, and much of the delivering is done by the boy. The routes are laid out with reference to the work that can be done in the periods that delivery can be made, the last being after the stores have closed for the day. The last wagon is into the station by 9 in the evening, and often before that time, although at some seasons of the year, as in holiday rushes, for instance, the time may be considerably later.

System of Delivery.

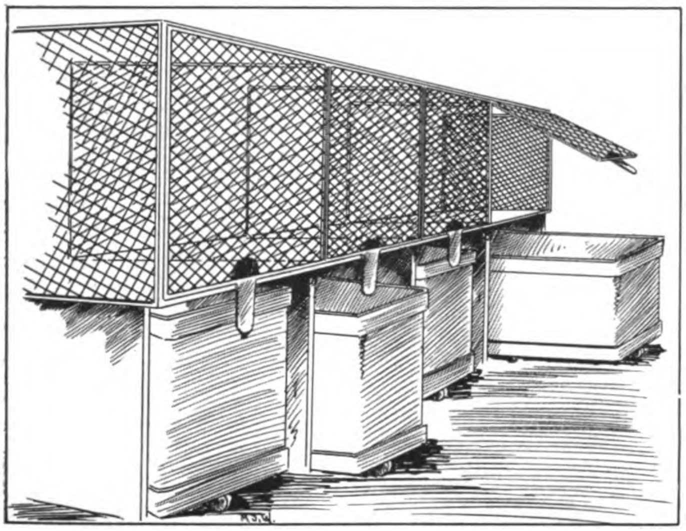
The people of Boston have been educated to receive their purchases the same day they are made, and while it would appear that many would be absent in the evening and there would be differing causes why many people could not be found, it is a fact based on long experience that comparatively few parcels are brought back into the station. The company makes transfers to other express companies and these, too, will make delivery in the same manner at a distance of 20 miles, though in such instances the packages are sent by passenger trains that leave Boston not later than 5 in the afternoon. The number of packages handled a day may be roughly stated to average with 15 wagons approximately 220, but there is considerable variance and it is probable with the reduction for transfer that the men will deliver from 150 to 250, these being the minimum and maximum figures. That the routes are comparatively short and the deliveries are close together will account for the high average, for in department store work the delivery of 100 packages is regarded as a good day's work. The drivers have to make collections on C. O. D. packages and each day settlement is made at the office and in turn adjustment is made with the houses sending out the packages, and returned packages are accounted for.



The Department of the Shipping Room Devoted to the Handling of the Bundles Delivered by the Jordan, Marsh Company's Delivery Equipment, Showing the "Tills" for the Packages and the Desks for Making Records.

The Boston Parcel Delivery Company has been largely responsiblefor creating the demand for quick delivery, for a score of years ago it was making no less

than eight trips daily from Winter street, using six wagons to a set. The hours of starting were 10, 12, 1, 2, 3, 4, 5 and 6. This was continued for a considerable



The Arrangement of the "Tills" and Carriers in the Department of the Shipping Room Where the Packages Delivered by the Jordan, Marsh Company's Equipment Are Collected.

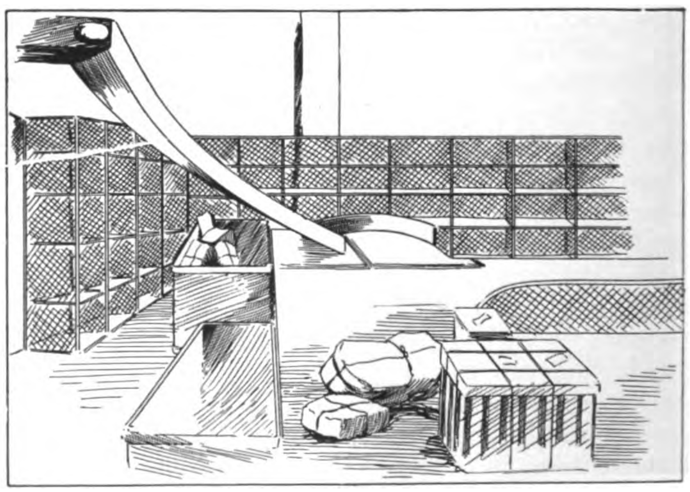
length of time, but the change was made to a fewer number of trips because on half of them not more than 50 per cent. of the vehicle capacity was carried, and, on the package basis, this meant a loss of money. Of these trips the first was practically devoted to exchange delivery and collection, the second was with a good load, that at 4 was with a big load, and the last was the largest of the day. The company afforded at that time the best service that was ever created for a city and was willing to even increase this, but it could not make unprofitable trips and so a change was made to the present basis of four trips a day and with distribution at its station, this saving the time of the wagons and the men to a considerable extent. With the expansion of the city and the increase of business into the suburbs the company continued to serve the original area, though the lines were extended to a small section of Brookline. But the character of delivery inaugurated by the company was demanded by the people living in the suburbs, and this, with the competition of the stores, brought about the distribution of goods practically the same day of purchase within a radius of approximately 20 miles, unless the conditions are unusual.

This company, however, does not give service to all of the stores. The Houghton & Dutton Company, Jordan, Marsh Company, R. H. White & Co. and the Henry Siegel Company each have service that includes the store equipment and the number of express companies that is necessary to reach the different localities. Besides the Boston Parcel Delivery Company there is the American Delivery Company, which similarly serves a number of stores and handles about 300,000 packages annually, besides doing more or less general transportation, and Craft's Parcel Delivery, which operates on a smaller scale, and many of the local express companies handle parcels delivered in that portion of Boston not reached by the regular "city" deliveries. These serve East Boston, Charlestown, Roxbury, Dorchester, Savin Hill, Jamaica Plain, Brighton, Forest Hills, Hyde Park, Roslindale, South Boston and other localities. Some of these companies do a very large business, but it is not confined to parcels.

System with Parcel Delivery.

The experience of those who have delivered parcels, especially in the sections where the routes are comparatively short and the customers close together, is that a great deal of the work is a matter of "legs," for this means that it is taking the packages from the wagons and to the houses. Where a package is delivered at the front door or any convenient entrance the time required is brief, but if it must be taken into a building and to an apartment, especially if it is a "collect" parcel, more time is needed. Often in the course of a day packages are left with other people than the customer, in the same building, in the next house, and sometimes after a search the package is brought back and is taken out on the next trip, or on a trip when the customer is expected to be at home. Many times the wagons call and take articles from homes to the store for changes, alterations, for cold storage, and for other reasons, and property so collected is at the expense of the store to which it is sent. Time is necessary for the work and if the work is not quickly done there is diminished profit.

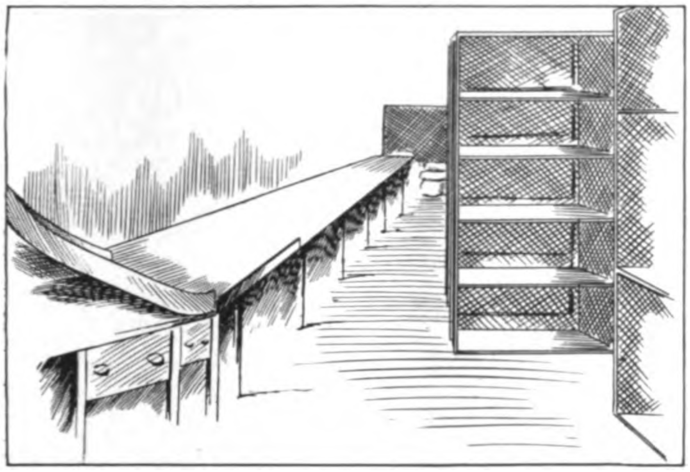
The minimum price of five cents for delivery within the "city proper" may appear to be a comparatively small charge, but it must be remembered that this merely calls for the haulage of packages from the stores to the station, the sorting for routes and distribution. The Boston Parcel Delivery Company has been a profitable concern. It has been well and economically managed and its overhead expense has been kept low. The company has the advantage of long experience and the prestige of a satisfactory service to its customers and the people. The company is willing to give what anybody is willing to pay for. The



Section of the Local Express Division, Where the Bundles to Be Distributed by the Express Companies Are Sorted and Placed in the Different "Tills" Assigned to Each Company.

driver of each wagon has the assistance of a good boy and the routes are so arranged that under ordinary circumstances each can be covered in approximately the

same time. The system of records is such that clerical work is minimized, and experience has developed that it is intensely practical. For smaller contracts



The "Transfer" Division of the Jordan, Marsh Company's Shipping Room, Where the Parcels Bought with "Transfer Books" Are Collected and Made Ready for the Delivery.

the price a package is larger, but the volume of business is more uncertain. The wages paid are moderate, but are sufficient to insure reliable help, and and the long experience of the company makes it possible to afford a protection to all its customers and the people. The length of the routes traversed will vary from five to seven miles, and a horse and a half is the allowance for each wagon. In the event of extra demands upon the service this can be provided temporarily by additional trips and the use of spare men. Normally the horses are not overworked, for good attention is as necessary as economy.

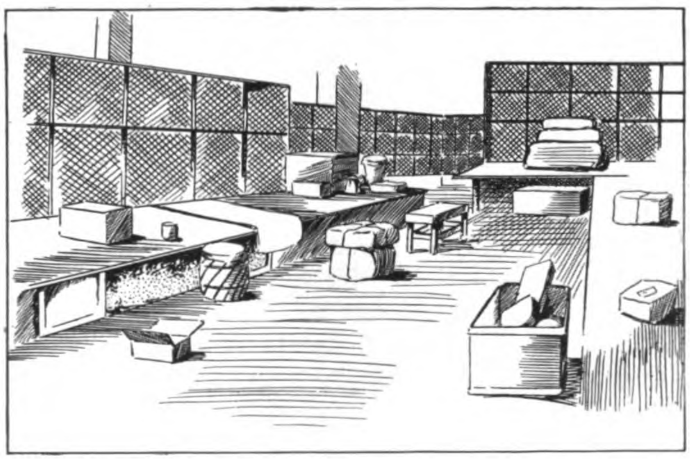
The American Delivery Company operates from 12 to 15 wagons, practically the same in construction and fitting as those of the Boston Parcel Delivery Company, and besides the delivery of store packages it distributes samples for numerous companies and will undertake any distributing work. The basis of payment for this service is approximately what has been stated, five and six cents a package within the "city" when contract is made, and where stamps are bought the price is $7.50 for 100. The price for a single minimum weight package is 10 cents, and the basis of counts is the same. Packages weighing in excess of 100 pounds are not accepted unless for the accommodation of a customer.

With the other companies the delivery rate is the same basis, but where a transfer is made to another company each receives the minimum rate. To illustrate, where a parcel is taken by one company and transferred to another the charge is double what would be charged for the handling by the one company. The package sent to Malden, for instance, will cost 10 cents, and the transfer is made by the collecting company to the station of the delivery company, where it is again collected and delivered. As a rule the companies have contract with each other, for there are formalities to be regarded with reference to collections, exchanges, losses, etc., which must be made through the collecting company, and there are responsibilities of this character that require a definite understanding. It is necessary for the stores, the customers and the express companies that these matters be given prompt attention.

Sorting of Packages.

Where the distance is greater the price is more, this depending naturally upon the number carried and the contract that can be made. Each large store makes contract with the express companies for delivery outside of the radius in which its own equipment affords service, but the policies of each differ. In some instances as many as 40 express companies make regular deliveries for a single store. The number of packages may vary materially, but in every case a contract is made for the work. Where contracts of this kind exist the wagons of the company call at the stores and take the packages. If the distance is short the haulage may be by wagon, by automobile, or the freight may be sent to one of the railroad terminals and shipped by express or passenger trains to the destination. Wherever received the packages are taken to a station, sorted and distributed, and considering the distances much of this work is quickly done. The custom with the suburban express companies is to sort the packages for routes and distribute them as do the parcel companies.

In New York and other cities the zone system or plan of distribution is often the vogue, this meaning the establishment of stations at different distances from the stores and conveying the packages and goods by wagon, automobile or train from the stores to those stations, where they are sorted for routes and distributed by wagons or motors owned or rented, or by men who have contract for this work when the volume of business does not justify store equipment. In one sense this is followed by the express companies centring in Boston. Some sort the packages on the sidewalks, as is the custom with all but one of the Boston stores, and leave with the goods ready for distribution. Others sort and arrange them at the stations. This work, however, cannot be done until the packages are

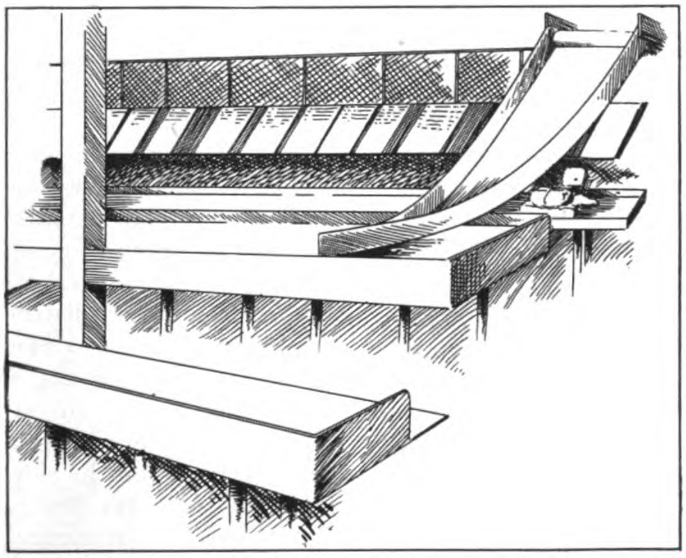


One of the Nine Packing Rooms of the Shipping Department of the Jordan, Marsh Company's Store, This Being Used for the Examination and Repacking of "Transfer" Sales.

ready for the wagons, and from 15 minutes to an hour is required, much depending upon the conditions in the shipping rooms and the celerity with which the goods

are sorted and packed for convenient handling.

The custom varies with the store, for no two have the same list of places for delivery. For instance, the Filene store has a list of 141 different localities in which delivery is made, and of these 18 are within the city of Boston, outside of the "city" proper. There are in Boston no less than 34 different sections or designations of locality. The White store lists 20 different sections of Boston, five of which are not listed by the Filene stores, and it does not list three that are on the Filene list. This comparison can be made with similar results with practically all the stores. The lists are posted for the information of the clerks so that the customers may be notified definitely when delivery can or should be made, and these usually state the times and if the store service or the expresses are used, Some stores group these localities under the name of the suburb, there being, for instance, two in Arlington, Chelsea and Saugus, three in Belmont, East Boston and Watertown, four in Everett, five in Revere and Dedham, six in Medford, Brighton, Milton and



Portion of the Division Where the Packages to Be Delivered by Parcel Post and Express Companies Are Received and Sorted, in the Jordan, Marsh Store.

Quincy, seven in Somerville and eight in Malden, Brookline and Newton. Because of this difference in policy it is not practical to determine the exact scope of service from these lists.

Several endeavors have been made to bring about co-operation of the large stores of the city in making delivery, and it was the support given this proposition that resulted in the organization of the Boston Parcel Delivery Company. Prior to 1898 all of the delivery was made by horse wagons, and in that year the Houghton & Dutton Company bought two Electric Vehicle Company's delivery wagons and used them for several years with more or less success. The machines were crude as compared with those placed in service in 1900 by the New England Electric Vehicle Company for public service in Boston. They were used in local delivery on different routes and, considering the inexperience with electric vehicles, the construction, the facilities for charging and the attention given them, did excellent work.

Pneumatic Tube Service.

The American Pneumatic Service Company established itself in Boston in 1901, this being a plant similar to that built in New York, Philadelphia and other cities. The central station was located at Essex street and Harrison avenue, where the branch postoffice station now is, and wooden tubes were laid in the street to stations at the South End, Roxbury and to Huntington avenue in the Back Bay, and by compressed air force packages were sent from the central station to the suburban stations, where they were sorted and distributed on routes by 20 wagons. It was necessary to deliver the packages at the central station from the stores and the collections were made frequently and the tubes were used constantly to supply the different sub-stations. The company did the delivering for the Shepard, Norwell Company and a number of smaller stores. In 1904 the United States government hired the Essex street station for a branch postoffice and used the tubes to send mail to branch postoffices which supplanted the delivery stations. The wooden tubes were replaced by metal and these exist and are used today by the postoffice. The company established a station in West Newton street and there continued to make delivery until 1909, when the business was discontinued. The company derives a substantial revenue from the use of its plant and exists today, for the government has similarly taken over its service in the other cities. The service was quick and satisfactory, but the size of the packages was limited to perhaps eight inches square and in weight to perhaps 20 pounds. Those of greater bulk or weight were necessarily delivered by other means.

Early Motor Equipment.

The Boston Auto Express Company was the first public service corporation to make use of motorized equipment. The company was organized in December, 1900, the head of it being Hugh Brown, president of the Hotel & Railroad News Company. The company purchased six Vehicle Equipment electric 3000-pound delivery wagons, which were delivered about August, 1901, and it contracted for 16 Knox single-cylinder delivery wagons. The company established stations in Chelsea, Brighton, Dorchester, Somerville and in Boston, and the parcels were collected in the city and delivered to these stations by the electric wagons, and then were distributed on routes. In Boston the company served the Houghton & Dutton store and a number of small houses, and also handled the out-of-town packages for the White, Stearns and Jordan, Marsh stores out of the city and in the sections covered by the company. The organization was thorough and the service given was excellent considering the equipment and its crudity, and the company would have undoubtedly continued, but Mr. Brown's health precluded his giving the attention necessary, and finally the business was discontinued in December, 1903, the electric wagons being sent to the St. Louis Exposition for service there, and the 16 Knox wagons were acquired by the Houghton & Dutton Company. These wagons were used with gradually

decreased numbers until 1906 and then the company turned to horses again for the principal part of its delivery.

E. P. Morse was treasurer of the Boston Auto Express Company and when the company wound up its affairs he became associated with the Houghton & Dutton Company as manager of the transportation department, and he continues to supervise the delivery of the company as assistant general manager. Capt. Harry F. Dutton and Mr. Morse have long been convinced of the utility of the motor wagon. The Knox wagons were useful, but were found to be not sturdy enough for the work, and they were in some instances rebuilt. The divided rear axles were replaced by solid constructions, jackshafts and double chain drive were substituted for the single chain, heavier springs were installed and 42-inch wheels were placed on the rear axles. These changes were not made with all. for as the machines become unserviceable they were disposed of, but the company now has two of these rebuilt wagons which are now known as Houghton & Dutton specials. The company purchased two 2000-pound General Vehicle wagons in 1909, another of the same make and size in 1910, a 1000-pound Lansden wagon and two Packard three-ton trucks in 1912. so that with the two rebuilt wagons it has eight motor vehicles in all in its service. Its horse equipment consists of 125 animals and 60 single and double wagons, teams of two horses being used for freight and furniture haulage.

Houghton & Dutton System.

In 1904 the company erected a building at Beacon and Ashburton streets and on the second floor of this fireproof structure made a combination shipping room, loading room and small electric garage. This department is reached by a long runway from Ashburton street. Three sides of this large room are devoted to the shipping and on the fourth side is the electric garage and the stock room in which the supplies and parts of the machines are kept. Three machines can be placed in this garage and there is a small charging panel at which three batteries may be charged. The centre of the department will accommodate a dozen horse wagons of about 20 motor vehicles. The centre is the loading space and about it on three sides are the 38 compartments into which the goods to be shipped are placed when sorted for the routes. These compartments are about four feet wide and eight feet length and have doors the full width from the shipping room and the loading space. They are the full height of the story.

There are three packing rooms in the building, and from these the packages are brought on trucks or carriers and by elevators to the shipping room floor. Spiral chutes will be used as soon as the reconstruction of the original building, now in progress, is completed, and the use of the elevators is merely temporary. Reaching the shipping room they are placed on inclined receiving runs, this to prevent accumulation and the consequent delay of the bottom packages. One run is for the small parcels and the other for the large. At the runs the packages are sorted and carried by fl trucks to the different bins or compartments, wh they are ready for the drivers. The records are ceedingly simple and are made out from the sales sl on billing machines in duplicate and each driver si for the packages he receives. The original sheet t he receives must be returned with a record of the position of the packages and aside from a check m for each parcel and his signature he has no entries make.

The wagons or machines are driven into the bu

Some of the Rates Charged for the "A" Service of the Ele Express, Which Means the Collection and Delivery of Packages by the Company's Wagons.

ing and backed to the nearest place to the comp ment that contains the packages for the route. loading is very quickly accomplished and there is confusion, no interruption by traffic, and it is alw sheltered from the weather. The department is ur the direct supervision of the shipper and he is alw accessible. In this department is also the office, wl the settlement of collections are made, and each

counting is made before another load is taken out. By relaying the wagons into the shipping department it is practical to load many times the number of packages taken out, and the loading space can be utilized as an electric garage without in any way interfering with the convenience of the arrangement. This shipping department was planned in 1904 when the building was erected, and it was ready for occupancy the following year. It is the only one of the kind in Boston, and is equalled only by one or two stores in New York. It might be said that this provision was made by the firm because of the conviction of Capt. Dutton and Mr. Morse that the motor vehicle would be the equipment that they would eventually use for delivery and the desire to have facilities that would yield the most satisfactory and economical results.

The electric vehicles are garaged in the shipping department and the gasoline wagons and trucks are garaged at Hancock square in Charlestown. The mileage of the electric machines is from 40 to 45 daily, and the gasoline vehicles considerably exceed this, for two of them are used for furniture delivery and the like. Much of the freight haulage is done with the horses. The store delivers in the "city" with the starts from the shipping department at 10, 2, and 5:30 daily, and the deliveries by the store equipment in Allston, Arlington, Belmont, Brighton, Brookline, Cambridge, Charlestown, Chelsea, Dorchester, East Boston, Everett, Forest Hills, Jamaica Plain, Malden, Medford, Melrose, Mount Auburn, Newton, Orient Heights, Revere, Roxbury, Somerville, South Boston, Waltham, Watertown, Waverley and Winthrop, and by expresses in Atlantic, Dedham, Greenwood, Hyde Park, Lexington, Mattapan, Milton, Neponset, Quincy, Roslindale, Stoneham, Wakefield, West Roxbury, Winchester and Woburn. These deliveries are made once or twice daily, from 10 in the morning until 5 in the afternoon. Nineteen of these places have one delivery and the remainder two. Those in Dorchester, Medford and Newton are made by the electric machines. Besides this there are special trips to make emergency deliveries. In addition there is the distribution by the express companies covering points more distant, as well as by the parcel post service and the Electric Express. In some instances the express packages are sent to the receiving stations by wagons and in others they are called for, but the local express companies always call. The parcel post packages are sent to the postoffice at frequent intervals. The company delivers orders to the value of $1 free in Massachusetts, except house furnishings, groceries and patent medicines, but all goods to the value of $5 are delivered free in New England, except sugar, flour and patent medicines. This delivery means to the nearest express, freight or postoffice, and no C. O. D. less than 98 cents is sent by express. All shipments are made from the store save furniture, which is supplied from a warehouse at Charlestown and is sold from samples.

Filene Shipping Department.

The shipping room of the Filene store is in the second sub-basement and it occupies the greater part of this section of the building. This store does not handle furniture, groceries or meats, and deals principally in articles of wearing apparel for men and women. The packages are collected on each floor and sent by a spiral chute to the shipping room, where they are received on a conveyor belt. The conveyor system consists of a long belt that extends through the centre of the room. Looking in the direction in which the belt travels at the right is a high bench under which are carriers. Beyond this is a series of bins or compartments beneath a top inclined at either side at an angle of 45 degrees, this top serving as a desk on which the drivers' record sheets are made out. Beyond this is another high bench and a long row of carriers. At the left is the office of the shipper and his assistants and the charge room. In the charge room all the charge packages are examined and the records made. At the end of the long belt there is another at right angles that receives the packages and carries them between two lines of bins, the one at the right for the store delivery, and the one at the left for the local express companies. The packages are taken from the conveyor and placed in the bins. After the records have been made they are placed in the carriers ready for the drivers. Again the conveyor turns at right angles and a short belt takes the charge packages to the charge room, and after the entries have been made they are placed on another belt that continues in the same direction. In a packing room the fourth angle is made and the belt takes the charge packages and those from the packing room back to the original place of starting, where they are dropped onto the main belt and carried around to the places where they are removed and placed in the proper bins.

The delivery of this store in the "city" is by the Boston Parcel Delivery Company, in a number of the suburbs and in Boston itself the company uses a fleet of 19 Ford delivery wagons, and outside of this area there is the contract service with express companies, the regular service of the New England and general express companies, the Electric Express and the parcel post. This means that the packages must be divided into groups in the shipping room, but there are no separate rooms for divisions. The packages are placed in the wheeled carriers after the entries have been made on the record sheets, and at different times the carriers are taken by the drivers, placed on elevators and carried to the sidewalk, where the bundles are sorted for the company's equipment and for some of the express companies making direct delivery. The facilities for shipping in this store have been well worked out and have been designed to do a very large volume of work with minimum handling. The means are extremely simplified, the belt conveyor encircling a rectangular space, with the bins and carrier spaces arranged so as to provide for any reasonable expansion through special or general sales. The carriers are located convenient to each series of bins and when these are filled additional carriers are available. The city delivery leaves the store at 10:30, 2, 4 and 6 each day, and the deliveries by the store equipment are at

1 and 6 each afternoon. The deliveries by the contract expresses are either once or twice daily, the time varying to meet the schedule of the express companies. The parcel post packages are taken to the postoffice whenever the quantity justifies, a load for a vehicle usually being taken. The shipping room list calls for 141 places of delivery outside of the "city," and of these 39 are served by the company's machines. The work done by the light delivery wagons is large in mileage, as much as 115 miles having been made in a day with two trips over a route, and the carrying capacity of the machines is comparatively small. The wagons are manned by a driver and helper and usually the delivery is made by the helper, the driver giving attention to the machine and the load, he having the responsibility.

Loading at a stated hour means that from 12:15 to 1 or later, and from 5:15 to 6 or later some or all of the machines are lined along the store in Hawley street. The drivers go to the basement, bring the carriers containing the packages up on the elevators (the illustration will show there are two of these), and the carriers are either left in the entrance and the bundles are carried to the wagons, or the carriers are taken to the wagons on the sidewalk. Sorting is accomplished under difficulties as during the time the wagons are loading the walks are usually thronged with people, for the first loading is during the lunch hour and the second when the people are leaving their places of business. Hawley street is narrow and there is a car track through it, so that it is necessary for the greater part of the packages to be carried along the sidewalk and packed in the order in which they are to be delivered. While the time required for this work may vary, not infrequently the wagons are from a half hour to an hour in the street. A permanent canopy overhangs the sidewalk the full length of the side of the building, but this does not cover the machines or wagons in the event of storm. Besides the store equipment the express wagons must be similarly loaded and though not as much time is required the space in the street is occupied. The demand of the people that the deliveries be made cannot be denied. The service must be made alike, and late in the afternoon the street beside the store has a long line of waiting machines and wagons. The shipping room handles the delivery quickly, but the necessity of having the machines and the wagons leave at specified times entails waits, and the elevators are decidedly limited in capacity.

The company began its own automobile service in July, 1912, with 19 machines, and these were garaged at Montgomery and Tremont streets until recently, when they were sent to a garage in Aberdeen street, in the Back Bay. The drivers are paid $16 weekly and the helpers are paid $9 each. The new building was occupied in September, 1912, and this structure was planned for meeting every requirement of the business. There is, however, practically no provision for loading the machines and wagons off the street, and it is impossible to change the conditions unless there is eventually a means found for making a loading room on the street level through which the wagons may be driven. The only manner in which this could be done would be by taking a section of the ground floor extending through the store, and this would mean the loss of much valuable space now devoted to sales departments. The delivery of the store will approximate close to 1,000,000 packages annually, and the cost will vary with the character of service and the localities served. It is necessary that extreme care be taken in handling the goods and the packages are more than ordinarily carefully packed, all of which adds to the expense. The average cost of delivery will approximate 12 cents each. The parcel post service has been found serviceable, but not always satisfactory, because of the condition of the packages when received by the purchaser.

Jordan, Marsh Company.

The delivery of the Jordan, Marsh Company is one of the best organized in the world, and it is only equalled by three stores, two in New York and one in Chicago. The store has nine packing rooms in the old building and the annex, and the collection of packages is made on each floor every 15 minutes or less. The old building has four stores and the annex nine. Spiral chutes carry the packages to the basements and in the old building there is a station where the charge bundles are sorted out, the addresses and the responsibility of the customers verified by means of card indexes. The bundles are then placed on a belt conveyor and taken to the shipping room in the basement of the annex. The charge bundles from the annex are similarly verified and checked. The bundles from the annex come down a spiral chute and are brought from the old building to a central distributing station, where they are sent by belt conveyors to the different divisions. One very large room is devoted to receiving the packages that are delivered by the company's own service, a second is used to collect the local express packages, a third for the general express and parcel post packages, a fourth for the collection of the purchases by "transfer," a fifth to the packing of the "transfer" sales, a sixth to the examination of goods that are returned for refund or exchange, a seventh for packing, and there are others for the clerical forces and for incidental work. The shipping department requires the whole of the sub-basement and its equipment, which is not ornamental in any sense, but is built for service and endurance, represents an investment of not far from $75,000. As may be assumed this was planned with great care and with a view of making provision for every need that might arise. Nothing that could be desired is lacking and it is practical to add to the equipment to even increase its usefulness.

The store delivers between 3,500,000 and 4,000,000 packages a year, and the average cost of delivery is seven cents a package, which is less than the expense a package of the other Boston stores, because of the greater volume and the fact that the wagons as a rule carry more a route. This price is applied to every

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

WIDE TIRES AND GOOD ROADS.

The wear of the steel tire upon a hard road surface is certain, and it must be evident that this wear is proportionate to the tire width. The more consolidated the roadway the greater the effect of traffic, for there is no resiliency to either surface or wheel. Obviously the only remedy is the widening of the tires to have such area that the pressure under load will be within what may be determined as the safe weight, though this is a factor that has never been satisfactorily established. Laws requiring wide tires exist in many states, but they have seldom been enforced. The reason primarily is that the wagon manufacturers have built wheels that, while they may have been sufficient in strength, have had narrow felloes and tires because this construction is cheaper from a manufacturing point of view, and competition has seemingly justified this assumed economy, especially as the purchasers paid less for the vehicles. There is no question that animals cannot haul as much with narrow tires as with wide and that there is a material loss in haulage with such equipment. This being so, the saving in initial price is trifling compared with the actual expense in continued use of wagons as generally built, to say nothing of the excessive wear of the roads.

This can be applied to all highways except such as are paved. The wide tire of the motor vehicle, with a comparatively light surface pressure, is not the same factor for wear that is the steel tire with a very heavy surface area. Rubber motor wagon shoes are by no means as wide as they ought to be, considering the loads carried, but this is not meant to imply that the wear upon the road surfacing is proportionate to the wear on the tires. The real factor is the weight a square inch of tire area. The steel tire and its heavy surface pressure cause internal movement of the road structure, and the wear of the rubber tire is confined to the surface of the highway. In any event the wider the distribution of the influence of the tire upon the roadway the better will both endure. The use of tires that are sufficient in size to insure long service and minimize road wear is, apparently, the best protection that can be given both vehicle and highway until the ways have been constructed to endure every form of traffic.

WHO DIRECTS DELIVERY?

Before attention was so generally directed to the economies possible or practical in haulage, it is probable that more than 95 per cent. of the highway transportation of the nation was left to the discretion of the driver. In fact, this condition very largely obtains today. This applies to loading, hauling and unloading. Where the owner supervised the work the efficiency was not necessarily high. Custom, the example of others, was regarded as a sufficient guide. In every instance, however, where economy has been the main object sought, this has been accomplished only by the greatest care and attention to detail. System and supervision is absolutely necessary.

While it is true that exceedingly capable men may have begun at the bottom of transportation work, it is also a fact that capacity has been generally recognized. If the driver is permitted to exercise his judgment with reference to delivery service it is reasonable to assume that the standard of efficiency will be practically what he cares to make it. In large transportation work every detail is planned with extreme care, and the efficiency is relatively high and the economy is at parity with the supervision. The man who can give the same attention to his haulage that he does to any other detail of his business can obtain results, and it might be well to emphasize that it is only through accurate knowledge, not estimate or supposition, that economies can be brought about.

To determine economy or waste it is necessary to establish a definite basis from which comparison can be made. Because of the variables what will serve in one locality or business cannot be applied generally. Averages are not sufficient. The only logical foundation is that obtained by carefully kept record, and in the absence of this information it is desirable to have such accounting system as will afford the detail, and continue whatever may be necessary to demonstrate loss or gain. The supposition that the detailed statement of another business is adequate is nonsensical, because of the difference in the factors, which could not under any circumstances be at parity.

SMALL BREWERY MOTOR DELIVERY.

Service of Beadleston & Woerz in Lower New York City, the Development of Eleven Years' Experience with Machines, Admirably Maintained and Affording Large Economy.

THOSE who have to do with delivery in New York realize that the conditions in the lower section of the city are exceedingly complex because of the generally narrow streets and the great volume of traffic passing through all thoroughfares in both directions. The streets extending north are intersected by those from east to west at distances that average 20 to the mile, this giving the block a width of less than 250 feet from north to south and length from east to west of from 500 to 1000 feet. Because of the comparatively small number of highways at the south end of Manhattan running north the traffic is necessarily very heavy in them, and as these must be crossed by the traffic from east to west and vice versa the interruptions are very frequent. From 6 in the morning until 6 in the evening the highways are crowded, and during the remainder of each day they are well nigh deserted.

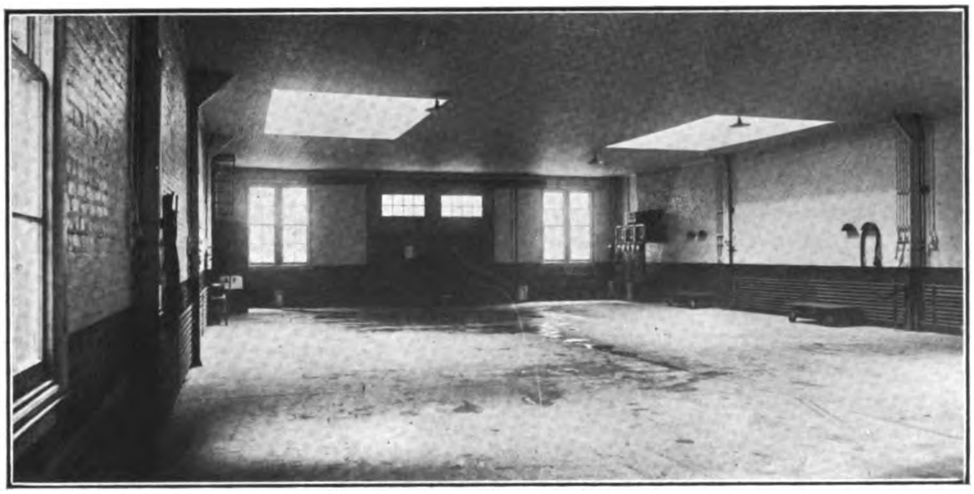
Because of the lower part of the city being largely given over to business, the high rentals limiting the areas of shops, stores and warehouses, the large number of transactions, receiving and delivering, is practically a daily necessity, and, as may be assumed, there is more or less delay in loading or unloading vehicles because of the absence of adequate facilities, or, to put it another way, the impossibility of places of business making provision for handling stock of any kind in the least time and at a minimum of expense. Add to this the loss of time through the congestion of traffic and it will be apparent why it costs more for transportation in New York City than in any other place in America where the streets are paved and improved.

This comment is made from the fact that any concern doing business in what is regarded as lower New York pays a greater price for delivery and haulage generally than in other parts of the city where the conditions are more favorable. There is no probability that there will be material improvement in the thoroughfares, and with the increase of business the only apparent relief that can be brought about is through street economy—the substitution of vehicles requiring less space, and this means the eventual use of the motor wagon or truck. As will be evident it is necessary for the conveyances to move constantly through the traffic, and as night haulage has not been considered nor business conditions adapted to more evenly distribute the volume throughout the day, the concern doing business in the extreme southern end is generally compelled to maintain a larger equipment than might be necessary were there less traffic congestion.

The brewery of Beadleston & Woerz, which was established many years ago, is at 291 West 10th street, and the property extends through the width of the block to West 11th street. Though small as compared with some of the mammoth breweries of the metropolis, it does a very substantial business, and its distribution is over the city proper, but does not extend in large volume into the suburbs and surrounding cities. Like all breweries conducted by men who were trained to the economies of Europe, and which are yet noticeable in plants in which these methods have been continued because of such training, the delivery department includes a blacksmith shop, wheelwright shop, paint shop and harness shop, all of which have been used for years. The delivery equipment consists of 10 five-ton and two three-ton electric trucks, and five gasoline trucks, a three-ton Packard, a five-ton Hewitt, two five-ton Macks and one six-ton Saurer, about 35 horses and a number of horse trucks and wagons.

The Fleet of Trucks in the Delivery Service of Beadleston & Woerz, Brewer, at 291 West 10th Street, New York City.

The delivery of this brewery is scattered well about the city, but there are localities where the customers are more numerous than others. A considerable part of the deliveries are made within what may be regarded as the section where the traffic is most congested during the day, and the others are where there is more freedom of movement. The company, however, does not do much business that might be termed casual or transient, because such patronage has not been found as profitable as the constant custom, and there is not much need of special service to meet the occasional



The Interior of the Garage for the Electric Trucks of Beadleston & Woerz, West 11th Street, New York City, Converted from a Stable.

demands of parks, places of amusement, etc., during the summer months. In other words, the business has been developed without regard to uncertain patronage and careful attention has been directed toward serving regular customers.

The first truck bought was built by the Electric Vehicle Company, of five tons capacity, which is numbered 98, and it was delivered May 15, 1902. This machine was worked carefully and, considering the capacity of the battery, it gave excellent results. This was followed by a second and then a third machine of the same make. The experience was varied and under all sorts of conditions. Despite the comparative crudity of the trucks as contrasted with those of today and the limitations by mechanical construction and the batteries the work was found to be more economical than with horses, to say nothing of the greater elasticity and the reserve when the volume of business increased, for the deliveries may be 300 per cent. more in the extreme hot weather than in midwinter. The first trucks were garaged at the stable of the company, and after the utility of the machines was well established, this extending over a period of about four years, the conclusion was reached that as the business increased and additional vehicles were required the animal equipment would not be added to.

The first gasoline truck was bought about six years ago, and then a small brick garage was built, this having capacity for 10 machines by crowding. In this garage a charging panel was installed that will charge five batteries simultaneously and the machines were divorced from the stable. The motor equipment was placed in charge of the head of the delivery department, Ernst Reinhardt, who had supervised the deliveries for 20 years, and he was expected to obtain results. When the first truck was purchased a capable machinist, who was familiar with electricity, was instructed to give it whatever care was necessary. With realization of the need of systematic attention he was held responsible for the condition of the machine. It was bought for business purposes and it was necessary that it be operative, but deterioration was not to be permitted.

The mechanic caring for the truck was intelligent and he studied it. He made a careful study of the battery. He was encouraged to attain proficiency, and he did so with a commendable thoroughness. He acquired sufficient skill to rebuild the batteries and to develop their capacities to the limits. When the gasoline truck was bought it was turned over to him with the expectation that it would be similarly kept. But this machine was bought without a body and Mr. Reinhardt had his own shop produce an equipment that to his mind was exactly suited to his purposes. Mr. Reinhardt transferred drivers from the horse wagons to the electrics, and he found them in every way satisfactory. Then he educated others until there was not a man driving who could not drive horses and trucks. He had his own ideas of competency and men who could prove themselves efficient by his tests were hired. When the gasoline truck was placed in service he similarly educated his men to the use of it. With this system he was never without satisfactory drivers should any of those driving the trucks be incapacitated.

The business of the company increased and as it did so additional electrics and gasoline trucks were bought, there now being in the service the three Electric Vehicle machines and nine General Vehicle trucks. No more horses were bought to meet the in-

crease of business, but the stable was kept up to the number of animals that had been in service because these had a use that was regarded as economical. But so satisfied is the company of the efficiency of the motor trucks that it is not intended to buy horses and as the animals now used become worthless for the work they will be disposed of. It is expected to add two trucks a year, each taking the place of six horses, until the equipment is motorized.

A horse stable in West 11th street has been converted into a garage. This is a single-story brick structure that is 102 feet length and 48 feet width, with several large skylights besides the end windows and a wide door, that is practically free from posts. No equipment has been installed that will take from the floor space and it is believed that this will be sufficient to meet the requirements of the company for a considerable length of time. All of the electric trucks are kept here and the old garage is given over to the gasoline machines. The charging panel will charge 16 batteries at the same time, and it is apparent that this would serve for at least double the number of trucks now in use. A section of this building is used as a battery room, where whatever work is necessary is performed.

The old garage is used entirely for the gasoline trucks and as a repair shop, it having such facilities as are needed, much of the work being done at the blacksmith or machine shops, and all the bodies are built in the wheelwright shop, while the painting is done by the company's men. The garage is in charge of the engineer, as the head mechanic is known, who has a machinist assisting him, and these two men care for all the trucks, but the charging is done at night by a man who is experienced with batteries. The rebuilding and overhauling of the batteries, however, is done by the engineer, or under his supervision. The engineer has regular hours, but when necessary he gives whatever time may be required nights.

As to the maintenance of the electric machines the three old trucks are in service and are doing excellent work, while the six-year-old gasoline machine is running admirably, having recently received an overhaul. The work is hard and the trucks are not spared, but they are well kept up and they are carefully driven. These vehicles are economical —just how profitable as compared with horses is not stated —but this fact is evidenced by the statement that the company will buy no more animals, and when much of the work is done where the horse is assumed to have the greatest value in haulage.

The trucks are worked according to the routes, some covering greater mileage than others, and under ordinary conditions most of them make two trips, returning to the brewery for the second load from 11 until 1. The average load of a five-ton truck is from 50 to 56 half-barrels, but more than 50 is seldom carried. Each driver supplies his customers and he is expected to keep the ice boxes filled so that in the event of extreme heat where the consumption is large, or in severe winter weather when a trip might be omitted, there will be a sufficient supply on hand. By this system a day or even two of bad weather, such as snow to a considerable depth, does not inconvenience the customers, and in periods of intense heat an extra trip will amply provide for all requirements.

The success of this policy is in first filling the ice boxes of all the customers and then making the deliveries regularly, each always having such reserve that there will be no shortage in event of excessive demands. Should it be necessary it is possible to "boost" a battery, or even to replace it with another, but usually the battery capacities are kept high. The mileage of a truck will range from 20 to 35, but the average will exceed 25 daily. The crew of a gasoline truck is two men, while one man handles an electric machine.

The shipping department and loading platform are at the 11th street end of the plant, and in the office of the shipper is a blackboard on which is placed each afternoon the orders to be delivered the following morning, and when the men return at noon their orders are posted before the afternoon trip, this record being necessary in the event of a change of drivers. The blackboard merely gives the total of each size of container to be taken out, and the distribution is made from

these, no order of specific containers being filled as a rule.

Besides the delivery much of the haulage of supplies, etc., for the brewery is made by the department, this being from various terminals and piers and from warehouses, and while for this work horses are generally used, the trucks are frequently utilized. This haulage is after the deliveries of the day have been made if the trucks are employed.

The drivers are expected to report the condition of their machines if there is need of attention aside from that given systematically, and such report is taken up by the engineer, who sees to it that the adjustment or restoration is made. Besides this the machines are regularly inspected and overhauled whenever need is evident.

A careful record is kept of the performance of each truck, and this is shown by a "Daily Trucking Sheet" which gives the number of the truck, the name of the driver and date and each load taken out in half, quarter and sixth-barrels, whether it be ale or bottling beer, the person who did the shipping, the number of the route, the time of leaving and returning, both morning and afternoon, the time of each trip, the reading of the odometer in the morning and at night, the mileage, the gasoline consumed in gallons, cylinder oil used in pints, the quantity of grease used, the weather and the road conditions. It will be noted that this is a combination blank and can be used for both gasoline and electric machines. The blanks are printed on a heavy, tough paper and are perforated for loose leaf binding.

In addition to this there is another record of each truck that shows daily mileage and the work done, this including the date, the time of leaving in the morning, the time of return, the load carried, the name of the driver, the odometer total and the mileage for the day. This is kept in a book that contains a statement for the year. In addition to this there is a record kept of each tire, this showing the date of purchase, the factory number of the tire, the license number of the truck on which it was in service, whether the truck is electric or gasoline, the date of installation, the name of the make, the record of the odometer when installed and the reading when removed. Thus the company has a note of each tire in use and can compare these as desired, as the tires are entered according to the serial number of each maker.

There are no trucks in service in New York that are better kept, and there are few that can show records of service that will compare with them, which is due to the care and attention given.

Six two-ton trucks were recently shipped to Manila, P. I., by the Gramm-Bernstein Company of Lima, consigned to the American Hardware & Plumbing Company, which has been one of the largest dealers in motor vehicles in the Philippines. This is said to be the largest shipment of trucks of a single size ever sent to the islands, and it is expected that the consignment of other models will follow.

HAUL TANK CARS WITH TRUCKS.

Novel Use of Two Couple-Gear Trucks at S. F. Bowser & Co.'s Plant.

S. F. Bowser & Co., Fort Wayne, Ind., one of the largest manufacturers of gasoline and oil storage plants and equipment in the world, utilizes two Couple-Gear electric trucks to haul tank cars to and from its plant and a railroad in that city. The main track is 2600 feet length and with trackage that includes two tracks at the railroad, three switches at the factory and another at a foundry the total length is about 3400 feet.

When the tracks were first laid and ballasted with cinders the ballast was level with the tops of the rails. On this ballast the trucks are driven, hauling one or more tank cars. The greatest number hauled has been seven cars, having 12,000-gallon tanks, four of these being loaded. There are numerous curves, three of which have a radius of 100 feet, but the trucks have each hauled two loaded cars around these curves. The cinder ballast has been well consolidated by the tires and the traction is excellent.

The statement is made that there has been no failure of the trucks to do the work required of them, and that with adjusting and systematic lubrication the machines have been found much more satisfactory than was believed they would be. The two trucks do the switching for which a locomotive would ordinarily be used, and the work is naturally much more economical and convenient.

The Y. M. C. A. officials in several large cities who have been conducting schools for motor car drivers, are planning to extend the scope of their work to embrace instruction in the care, operation and construction of commercial motor vehicles. With the large number of such machines in operation in nearly every line of business, hundreds of men who formerly drove horse trucks have been transformed into motor truck drivers with comparatively little trouble, but the increase has been rapid and complaints have been made in many cities of difficulty in securing competent, reliable men. The proposal of the Y. M. C. A. is expected to meet a responsive chord among many motor vehicle owners.

The city of Toronto, Can., was recently the scene of a horse show. The exhibit in itself was in no way remarkable, for Canada has long been noted for the quality of horses it produces, but as a demonstration of the rise in favor of the motor car it was a unique and important event. Not only did hundreds of patrons of the show use automobiles in visiting the building in which the horses were exhibited, but commercial vehicles played a very important part in the preparations for the display. All the lumber and other materials utilized in the special rings and tracks were hauled by motor trucks, of which there are a large number in use in the Canadian city.

SINGLE WHEEL DRIVEN CART.

Electric Wagon Designed to Replace the One-Horse Equipment for City Work.

The Eldridge Manufacturing Company, 178 Devonshire street, Boston, Mass., is building regularly a type of machine that was first seen at the Boston truck show, where the exhibit attracted much attention because of the departure from conventional practise. The type was first originated by the chief engineer of the Third Avenue Railroad Company, New York City, who conceived its use for the haulage of ashes and the construction was improved upon by the Eldridge company.

The machine illustrated is the first built and it is in the service of the Metropolitan Coal Company, being used for all purposes where a single horse and cart could be used. The capacity is 4000 pounds and the greatest speed is five miles an hour. The chassis frame is a steel angle that is "necked" from the centre cross section forward, the angle being curved to supply the usual front cross member, and it is continuous from the rear cross member. This frame has a slight "lift" at the forward end. The frame is mounted on a solid axle.

The front end of the frame carries a heavy cast steel plate, in which is cast a base for the fork or yoke that is supported by the front wheel. This plate is bolted to the frame. The driving wheel is mounted in a fork practically the same as is the front wheel of a bicycle, and the axle on which the wheel revolves is fixed in the ends of the fork. On this axle is installed the motor. The motor is approximately three horsepower and it is built to sustain about 300 per cent. overload temporarily. The ends of the armature shaft carry pinions that mesh with racks formed in the outer edges of the discs that form the wheel and the reduction is 24:1. On either side of the wheel are brake drums with external contracting brakes operated by a pedal and connected with cable so that the braking influence is equalized.

The fork above the wheel has a heavy shaft that exactly fits the base bracket of the plate, and a collar and a large nut that threads onto the bracket retains the shaft. On the upper end of the fork shaft is mounted the 22-inch hand wheel, and there is no bearing, but the shaft can be turned easily in the plate. Below the main frame, back of the front wheel and forward of the rear axle is the battery cradle. This cradle is loaded from the side, the sides being removable. The cradle is supported at the corners by heavy lugs that are carried on four guides, with helical springs above and below the lugs, this protecting the cradle against road shocks or stresses. The controller is mounted upright at the left side of the frame, this being of the street car type and fitted with a removable lever. The dash is a curved piece of sheet metal that is placed as a protection of the driver in the event of storm. The driver's seat is built for one and it is supported on full elliptic springs.

Directly over the rear axle are the brackets attached to the frame that carry the body. The body is heavy sheet metal and it is supported by a bar, the ends of which form trunnions that turn in the brackets. The trunnions are carried on helical springs that are compressed when the body is loaded and which have sufficient strength to prevent the body rattling when unloaded. The body floor slopes forward from the rear to the centre, and when dumped this section is vertical, insuring the complete discharging of the contents. The body is so balanced that it can be lifted easily when loaded, and when dumped the rear edge clears the ground by several inches.

The Electric Front Wheel Driven Cart Built by the Eldridge Manufacturing Company, Boston, to Take the Place of the Single Horse Equipment.

The front wheel can be turned so that the machine can turn as on a pivot, this permitting its use in very small spaces, where no horse vehicle could be worked, such as alleys, in courts and the like. The battery capacity is sufficient for 25 miles, and the power of the motor will pull the cart loaded through soft earth or other material, and it can be used on any grade up to eight per cent. with much economy. In the service of the Metropolitan Coal Company the cart is used for delivery of coal within a radius of two miles, and it has been found to meet a very exacting requirement with full satisfaction.

The mileage capacity of the machine is about twice that of a horse cart, and with the saving of a driver's wages it is expected that it will prove to be decidedly economical.

TIRES FOR ELECTRIC VEHICLES.

Manufacturers' Representatives Maintain That There Should Be Collaboration Between the Tire and Truck Makers to Produce Definite Standards of Production.

OF SPECIAL interest was a regular meeting of the New England section of the Electric Vehicle Association held at the Edison auditorium, 39 Boylston street, Boston, the evening of June 19, the subject for discussion being "Tires for Electric Vehicles," at which time several short papers were read and there was a great deal of general discussion relative to the quality and size of tires suited for different types of machines. The consideration was with relation to shoes for both pleasure cars and service wagons, but much of the time the references were particularly directed toward the latter types.

The meeting was presided over by Fred M. Kimball, and he appointed a committee of three to represent the association in the preparation of a paper to be read at the meeting of the New England section of the National Electric Light Association in September, this being the same committee that represents the Electric Motor Car Club of Boston.

The first paper was read by Alexander Churchward, a well known engineer, who is now connected with Gray & Davis, but who has been particularly active in research and experimental work for the association, and who has given a great deal of attention to the composition of tires suited for electric machines. This paper was as follows:

The subject of tires for automobiles is a very interesting and somewhat complicated one. No doubt most of you realize that tires make a very big difference in the energy consumption in watt-hours a ton-mile; i. e., in other words, the mileage your vehicle will make depends largely on the make of tires used.

The tire has the greatest influence of any part on the mileage. To illustrate this I will give the result of some tests on hard, level asphalt, and using data collected from eight different makes of tires: Taking the Palmer, single tube, as a unity: No. 2 tire takes 15 per cent. more; No. 3 takes 32 per cent. more; No. 4 takes 33 per cent. more; No. 5 takes 43 per cent. more; No. 6 takes 58 per cent. more; No. 7 takes 63.5 per cent. more. All the above are known as electric special tires and cover some of the best known makes.

The standard, pneumatic, gasoline tire takes 69 per cent. more; while the solid tires, compared with the unity tire (the Palmer, single tube) take from 42 per cent. more up to the extreme of 110 per cent. more. A very well-known solid tire compares very favorably with some of the special electric pneumatics, by taking only 54 per cent. more.

Some special tires of the "block" type have been built that take only 40 per cent. more; but I believe that it is not due to the special construction as much as to the good material which they put into this special construction of tire to make it hold together.

It is obvious that I cannot mention the names of the different tires used in the above test, as it would be unfair to the tire makers.

I took one electric runabout, and with 30 cells of 15 thin plate battery—and with Palmer tires—I could get as high as 115 miles at 16 miles an hour. These were double tubed. While with another make of special electric tire I could get only 82 miles at 16 miles an hour. With ordinary pneumatics I could get 68 miles at 16 miles an hour; while with a good grade of solid tire I could get as high as 68 miles at 16 miles an hour. So you can see what effect the tires do have on the mileage of the vehicle.

Some time ago I took up with the standardization committee of the Electric Vehicle Association the matter of standardization of tires by tractive effort per ton-mile; i. e., the amount of power to transport a given load at a given speed; and I believe it will be accomplished sooner or later, and that we will be able to get a standard tire which will put everybody on the same basis as far as mileage is concerned.

At the conclusion of the paper it was suggested that it would be well to hear all the papers and have the discussion relate to all of them, and this course was followed. The second paper was read by James E. Hale of the experimental department of the Goodyear Tire & Rubber Company, which dealt with the subject from the engineer's point of view. The writer's observations were more general than specific, he pointing out that tire manufacturing was a problem that presented many aspects. What was wanted by the users of tires was high efficiency and long mileage, and the makers were endeavoring to meet these requirements so far as was possible. The highest quality with reference to efficiency in the consumption of energy is not generally realized in the tire that has the greatest endurance, for the composition of the two must necessarily be in every way different. There is with all tires the element of internal friction to be dealt with, but as a rule heating is more marked in pneumatic shoes. He went on to demonstrate that when high resiliency is realized in a tire it is not enduring, and when extreme endurance is obtained the resiliency is lessened, it being impracticable to obtain both qualities. He believed that the conditions of overloading and under inflation were very largely responsible for what was regarded as inefficiency and failure, and that it was absolutely impossible to build a tire that would endure unless it was used within the limitations comprehended in its design. One of the greatest causes for tire destruction is the continued impact with the inequalities and obstructions of the road. The tire companies were compelled to give high standards and then the shoes were not used as they should be used to justify the expectations of the users.

T. H. McGiehan, general manager of the Motz Tire & Rubber Company, Akron, O., commented on the requirements with reference to tires, and he maintained that the absence of a standard by which it would be possible to determine resiliency was a condition that complicated the problem. The manufacturer could produce exactly what might be desired with reference to resiliency, but through lack of a standard or standards it was impossible to produce what might generally meet all requirements. If the vehicle manufacturer established precise specifications with reference to resiliency the tire maker could produce what would meet them, but this need did not appear to be realized by any of the car or wagon builders. From the viewpoint of the manufacturer of tires it was manifestly impossible to have compounds and proportions that would each be adapted to so widely varying requirements, and unless there were complete and definite understanding there could be no change.

The following paper was read by W. W. Duncan of the Hood Rubber Company:

Tires for electric vehicles may be divided into three classes: Pneumatics for light vehicles, cushion (such as the Motz) for

light vehicles, and solid tires for trucks. We deal entirely with the last named class, particularly for trucks weighing with load 8000 pounds and over.

The electric truck man looks at a tire from an entirely different standpoint than a tire manufacturer. It is to his interest, from a point of salesmanship, to have a truck give a maximum number of miles per charge of battery. To do this he has raised his batteries higher up, he has changed the design of the truck and he has chosen his tires from this standpoint.

Now from the tire man's point of view what the user desires is greatest miles per tire. Therefore the tire manufacturer endeavors to get on the proper size tire to carry the load at the speed required.

Rubber is a peculiar substance. It and any compound of it is practically non-compressible. Therefore under a load a solid tire must compress into some other shape than that in which the tire is built. The amount which is displaced varies with the composition of the compound and the load. Various shapes are recommended for better and worse, but the above fact holds true. Therefore, if the tire does not contain sufficient rubber body under the wheel to support the load it will compress so that the movement of the rubber compound in displacement is greater than the adhesion of the softer rubber to the hard base. When this happens, and it always happens if the tire is too small, friction develops, at each revolution of the wheel, in the body and the tire is soon gone. Again speed comes into it.

The rubber compound takes a certain amount of time to return to shape and if it does not have the time during the wheel revolution, the next shock on the road causes too great a displacement and a similar break as before. And now comes the point I want to bring up. The proper size of solid tire to carry the load and stand the speed does not usually give the greatest mileage capacity charge of battery. Therefore, if you choose tires from the truck makers' standpoint of mileage delivered from battery you are doing an injustice, not only to the tire makers, but also to the users.

Having an insufficient amount of rubber under the wheels not only causes quick tire deterioration, but also does not properly protect the truck mechanism from shocks and increases the user's repair bills and tire expense. I know of cases where a truck weighed 10,500 pounds and carried a dead load of 10,000 pounds, or a total of 20,500 pounds; 60 per cent. or 12,300 pounds, was on the rear wheels, or 6150 pounds on each rear wheel, which was equipped with dual five-inch tires. Our five-inch tire dual, which I believe is rated as high as any, will carry a maximum of 5500 pounds, and we recommended six-inch duals which would carry 8000 pounds, giving a good leeway. This increased the truck user's tire cost about $36 per tire, or $144 per truck.

The load on the front wheels was 8200 pounds or 4100 pounds on each wheel, and the truck was equipped with seven-inch tires, which would carry 4600 pounds, these being ample. Why were not the rear tires properly sized, as were the front? The owner naturally balked at putting on the proper size tire at extra expense, which also necessitated a change of wheel, although he knew he was not getting tire service, whereas if the truck had been properly equipped in the beginning he would not have thought of it. As it is he is changing from one make of tire to another, trying to get satisfaction which will never come, and cursing trucks in general.

Now what I want to point out is this: There must be collaboration between the tire manufacturer and truck maker; not between the tire salesman and the truck maker. The tire salesman often advocates a too small tire to make a sale. In this he is wrong and may mislead the maker. But the maker is apt to meet him half way because it decreases the cost in the truck. I venture to say that in more than 60 per cent. of the trucks we equip we have to change the felloes on the wheels to apply the proper sizes of tires.

I know of one case in Providence where we took up the tire equipment of a gasoline truck after every other tire man had given up the work. The truck was fitted with five-inch dual tires on the rear wheels. The owner overloaded the machine and it was driven at excessive speed. For an experiment we put on five-inch tires. These were torn from the bases in 2300 miles. We then put on 5.5-inch dual tires and the owner is going to realize about 5000 miles. This man needs six-inch dual tires, but we cannot fit them, because the truck is so designed that the felloes would interfere with the chains. We cannot properly equip the truck and the owner cannot understand why the truck maker did not, and consequently the owner is dissatisfied with truck makers and tire makers. Therefore, please remember in equipping your trucks to put on the proper size of tire to carry the loads, even at the expense of less mileage per battery charge. This result will be offset by the fewer repairs on the truck, increased tire mileage and general satisfaction. At the present rates for charging batteries with electricity the cost is cheaper per mile than is the cost of rubber tires.

Following this paper the discussion became general. Mr. Kimball sought to establish that the variance in wear with tires for gasoline and electric vehicles was due very largely to the difference in character of propulsion, the impulses of the explosive motor causing a succession of stresses upon the tread of the tire where it contacted with the road surface. The electric motor, however, has a uniform torque and there is not the variable strain caused upon a tire tread. It was to this condition, peculiar to each prime mover, that he attributed the greater endurance of tires fitted to electric machines. As he expressed it the action of the electric motor was uniformly even and the stresses upon the tire of the electric vehicle were the better resisted by the tire structure.

Mr. Churchward stated that the tests referred to in his paper were made with recording instruments, showing the exact consumption of power and the resilience of the tires, and the trials were made with the same vehicle over the same roadways, so that the results were variable only through the qualities of the tires. He believed that the method chosen was the only one that would determine precise results and establish qualities.

Mr. McGiehan suggested that the determination of the resiliency of the tire by the elasticity as shown by the bounce, in the same manner as steel is tested by the sclerescope, might be satisfactory, because elasticity could only be obtained through compounding, but to this Mr. Churchward replied that recording instruments were the more definite and reliable.

Mr. Hale maintained that to his mind the wear of tires was, aside from the abrasive influence, due entirely to the continuous impact with road inequalities, and that this condition could not be met with only by having the surfaces of the highways smooth and even, for it was not possible to make a tire that would have all the qualities and resistance to wear. It was practical to make a tire that would resist abrasion, but it was extremely difficult to attach an elastic and yielding material solidly to a base. The base of the tire must be such as will remain firmly fixed upon the wheel, and the strains of tractive effort, braking, and the like are resisted by the tire compound. He believed that with extreme mileage for electric vehicles the construction would not endure as well.

He said that he did not believe he was making too strong a statement when he said that the tire manufacturers were "sick" of making guarantees, because of the many conditions which they could not control, and he was of the opinion that there would shortly be a disposition to abandon guarantees, which would result in compelling the vehicle builders to furnish better tires, and it would be necessary for the owners of machines to require their drivers to be careful and economical of the tires.

Mr. Duncan believed that the vehicle manufacturers were inclined to under rather than over-tire the machines, and instead of making certain of a reasonable margin that would insure greater mileage and increased endurance they were willing to leave this to the tire manufacturer and the truck owner. Not only this, often there was no provision made for the fitting of shoes of sufficient dimensions.

H. L. Stockbridge, engineer of the Hood Rubber Company, maintained that Mr. Duncan's contentions were well established, and that while the tire manufacturer made his products to meet certain conditions, there was no definite standard by which the purchaser

of the vehicle could be assured that the tires fitted by the maker were what would give the best and most economical results. In fact there was an absence of that knowledge that should obtain, and there ought to be the standards by which the interests of the tire manufacturer, the vehicle builder and the owner would be best conserved.

The endurance of block tires for trucks was brought up and Day Baker, district manager for the General Vehicle Company, stated that he was decidedly interested in a test that had been made because of the supposition that block tires were not as enduring as solid tires. A truck used in coal haulage was fitted with solid tires and these were worn out in nine months, but this same machine was equipped with block tires and these had been running for 22 months and were not yet unserviceable. Mr. Baker said in reply to a question that the tires had been changed with reference to wheel position and that careful record had been made of the mileage and the work done by the machine.

Col. E. W. M. Bailey said that what was wanted more than anything else for electric vehicles was tires that would be specially adapted for the service and which would have qualities that would combine high mileage and endurance. He was of the opinion that there was a decided difference in the effect of transmissions so far as gasoline and electric machines were concerned, and there was no doubt in his mind that it was impracticable to obtain the same results from tires built for the two types of machines. In other words, there ought necessarily to be standards for each class of tire that would be understood by the different interests, and these could be used so that the best results could be obtained.

NEW ENGLAND CHARGING STATIONS.

Garage and Emergency List Prepared by the Boston Electric Motor Car Club.

The Boston Electric Motor Car Club has published under the title of "Pastime Journeys for Electric Automobiles" a booklet containing much desirable information, which has been placed on sale for the benefit of the motoring public. The contents include a summarized statement entitled "The Electric Automobile Defined," by H. F. Thomson of the electrical engineering department of the Massachusetts Institute of Technology, which sets forth the simplicity and ease of operation of electric machines.

This is followed by "The Why of the Electric Motor Car Club," which is stated to be a co-operative organization of all those in New England who are interested in the promotion of the electric motor car, this being an evolution from an association with a membership composed entirely of manufacturers and agents of electric vehicles, batteries and accessories. Among the benefits obtaining through membership are maps and routes for New England tours, charging station information, advice as to garages in which electric cars are given proper attention, the co-operation of the Boston city authorities in the establishment of parking spaces in the down-town sections of the municipality, interpretations of new laws and regulations governing the operation of motor cars, and the club is planning the establishment of a garage especially for the benefit of theatre patrons that will have washing and charging facilities, is now considering the proposal to inaugurate co-operative insurance, the instruction of mechanics and garage hands, the inauguration of a registry of motor truck drivers and the development of a bureau of information that will record data of electric vehicles and their mechanical construction that will serve motor vehicle owners.

The booklet contains routes and maps from Boston to Plymouth, Mass.; Boston to Portsmouth, N. H.; Boston to Worcester, Mass.; Boston to Springfield, Mass.; Boston to Providence, R. I.; Boston to Newport, R. I.; Boston to Lowell, Mass., and Boston to Lawrence and Amesbury, Mass., the longest distance routed being 95 miles. The list of charging stations shows that there are 208 of record, of which 28 are in Connecticut, Maine 25, Massachusetts 121, New Hampshire 17, Rhode Island five and Vermont 12. This does not include all of the stations that are available, and the list is being added to very rapidly. The stations are those of public service corporations, public garages and differing power plants where energy is available. The voltage, amperage and hours when service can be obtained is stated with reference to each station, and emergency stations are defined with the instruction that to these the probable time of arrival should be stated by telephone. Assurance is given the owners that the garages and charging stations listed can be depended upon for reliable and efficient service. These charging stations are available for all users of freight carrying machines and a copy of the list is especially useful for the driver of any vehicle sent out for a trip which includes more than the usual mileage.

William E. Metzger, who was a director of the Automobile Chamber of Commerce representing the Maxwell Motor Company, retired from that position and was immediately elected a director of the body as the representative of the Argo Electric Vehicle Company, Saginaw, Mich. Mr. Metzger has long been identified with the industry as a builder of gasoline machines, but this is his first association with a manufacturer of electrical vehicles.

"Electric Vehicles" is the title of a magazine which has succeeded "Ignition," published by the Electricity Magazine Corporation at Chicago. As the title implies the publication is given over to differing subjects that have to do with vehicles used for pleasure and service, and as may be assumed these are regarded from every aspect. The magazine is illustrated freely. Considerable attention is devoted to various electrical organizations, and there are, in the initial number, specifications of some of the best known pleasure machines.

ELECTRIC VEHICLE PRACTISE.

Characteristics of Design and the Constructional Details of the Standard Westinghouse Motors—Features of the Motors Used in the Couple-Gear Wheels and the Walker Rear Axle, Both Built to Endure Unusually Severe Stresses.

(By William W. Scott.)

THE description of the processes of manufacture of electric vehicle motors by the General Electric Company has been made with a view of making known the extreme care taken to insure factory perfect machines. This statement can be applied to the production of other manufacturers, for it is purposed to send out motors that have been found to meet every test, and to insure to the vehicle builder and the user what will afford long and continuous service under the most exacting conditions.

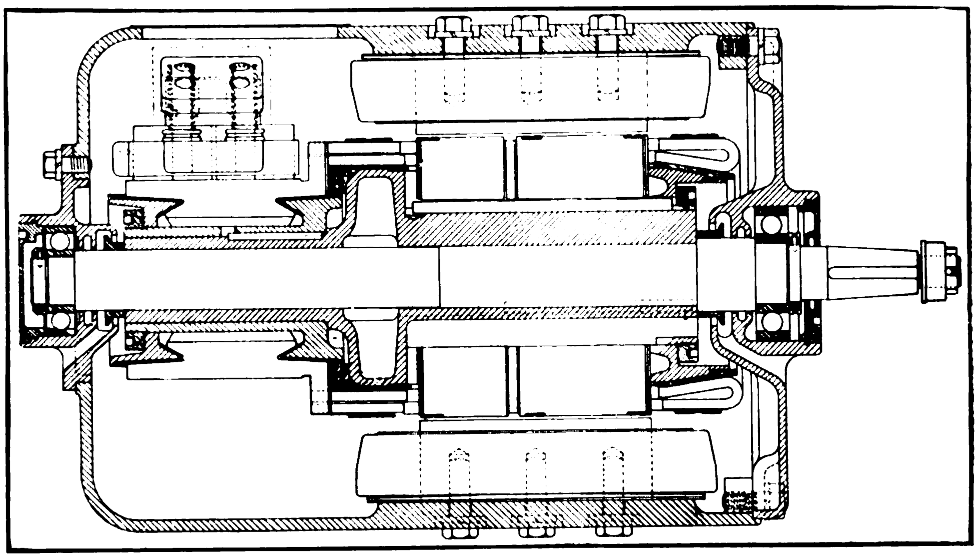
One of the largest builders of electric vehicle motors is the Westinghouse Electric & Manufacturing Company, the machines of this company being recognized as standard, and they are used by a number of well known manufacturers of cars and wagons. With reference to these motors what has been stated as to engineering and design may be accepted as fact, these being developed with a view of securing high efficiency, overload capacity, endurance and dependability, and the design has been worked out to economize space and insure simplicity and accessibility. These are built with capacities suited for varying types of batteries, voltage and mechanical systems as determined by analyses of the results from prolonged observations and study of actual operating conditions.

An examination of the accompanying drawings will show that the construction of the Westinghouse motors coincides closely with the General Electric machines so far as the application of principles is concerned, but there is, of course, a variance in detail of design.

The Westinghouse motor has the cylindrical frame that has been accepted as affording the greatest strength and which has the minimum bulk, for space required for installation and weight are two important factors. This is also a steel casting which is formed with the commutator end integral, there being increased thickness of the shell for approximately half the length of the frame from the pinion end, and this belt serves as a seat for the field pieces and coils. The frames are made in different sizes to standard patterns. There is at the pinion end an internal flange that serves as a seat for the end plate and to which the plate is bolted.

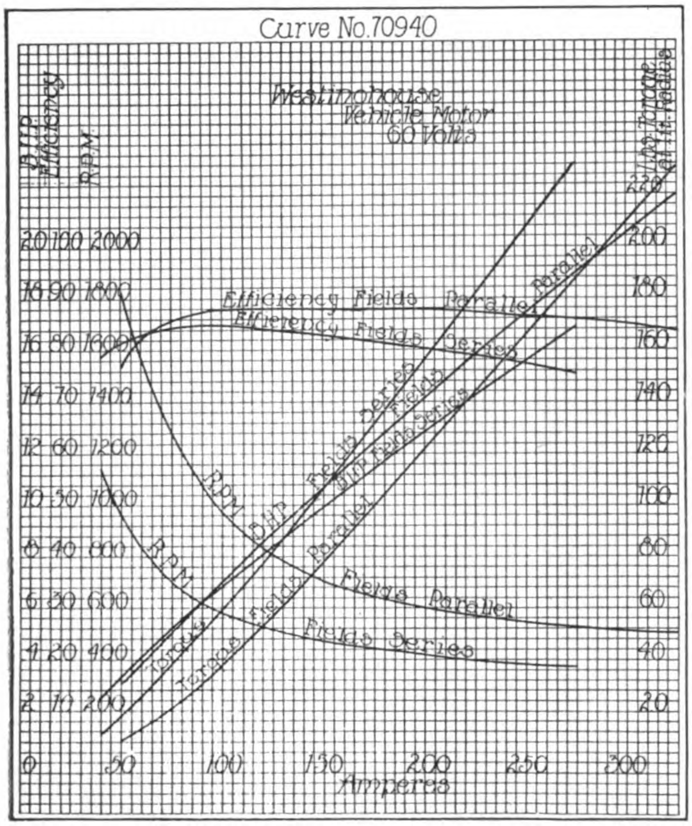
The end plate is a casting that has an opening for the shaft end through the centre, and this opening is shaped to carry the bearing and to conform closely to the shaft, there being three flanges between the bearing and the armature to prevent the flow of lubricant, while a drain insures against an accumulation of lubricant in a sufficient quantity to work into the motor case. At the commutator end of the motor there is an end bearing plate that is similarly formed and which carries the bearing, the end of the plate being closed by a cap screwed into the opening and secured by a cap screw.

The frame is carefully machined internally and roughly machined externally, or to any dimensions required for accurate mounting. There is in the shell at the commutator end a hand hole through which the commutator and the brushes may be inspected, and this is closed by a plate retained by screws, so that when assembled the frame is dust and water tight and is amply protected. A glance at the drawing will show the manner of securing the bearings in which the armature shaft is mounted.



Sectional Drawing of a Standard Westinghouse Vehicle Motor, Showing the Proportions and Relations of the Armature, Field Coils, Field Pieces, Bearings, Etc.

The armature is designed to produce definite electrical results and has specific proportions. It is a ventilated type and the core is composed of a series of thin sheets of steel that are cut in a die, having a central opening and a series of rectangular slots equidistant around the periphery, these having a depth about twice the width. The steel sheets are coated on either



The Performance Curves of a Standard Westinghouse 60-Volt Motor.

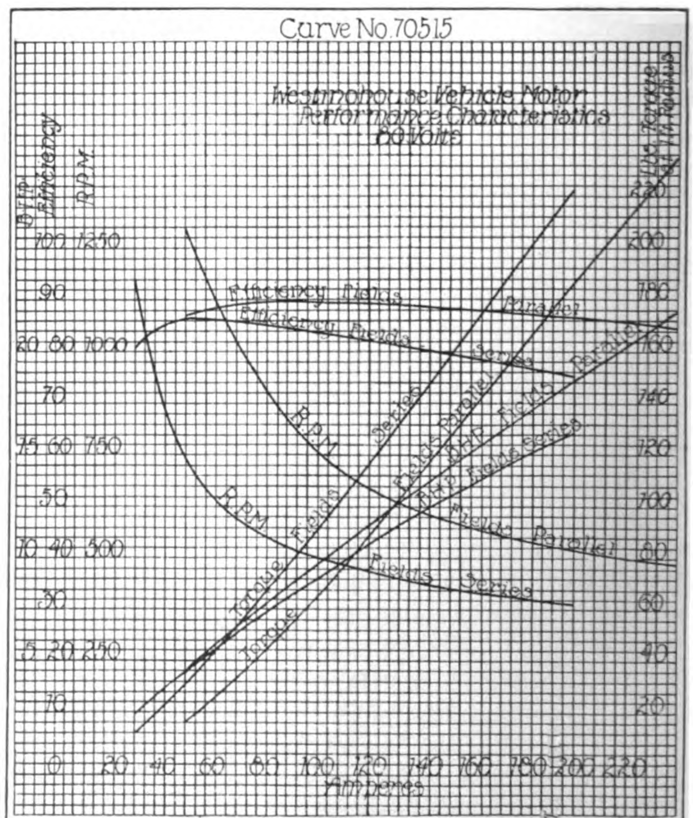
side with insulating material. The required number of these sheets are arranged on a cast iron spider and securely clamped, the spider having a collar, and at the pinion end of the spider is a plate that is retained by a collar that is seated firmly against the plate. The spider is pressed upon a steel shaft and is secured by a longitudinal key.

The core when assembled has the series of longitudinal channels into which the windings are placed, these being loops of groups of rectangular wire with the loop ends laid on the end plate, and the free ends are soldered to the inside ends of the commutator segments. These loops are wrapped with material that, when impregnated with a compound, perfectly insulates them, and the windings are firmly bound by a series of windings of wire that are soldered together, there being five of these bands encircling the armature. The commutator is assembled on a cylinder of molded mica with mica strips between each of the wedge-shaped copper segments, and the assembly is clamped by a collar at the end of the spider that is firmly screwed to its seat. The ends of the winding are soldered to the commutator bars and perfect contact is insured. The completion of the commutator is when the mica strips between the segments are milled below the surface of the copper bars, the channels being about .0625 inch depth.

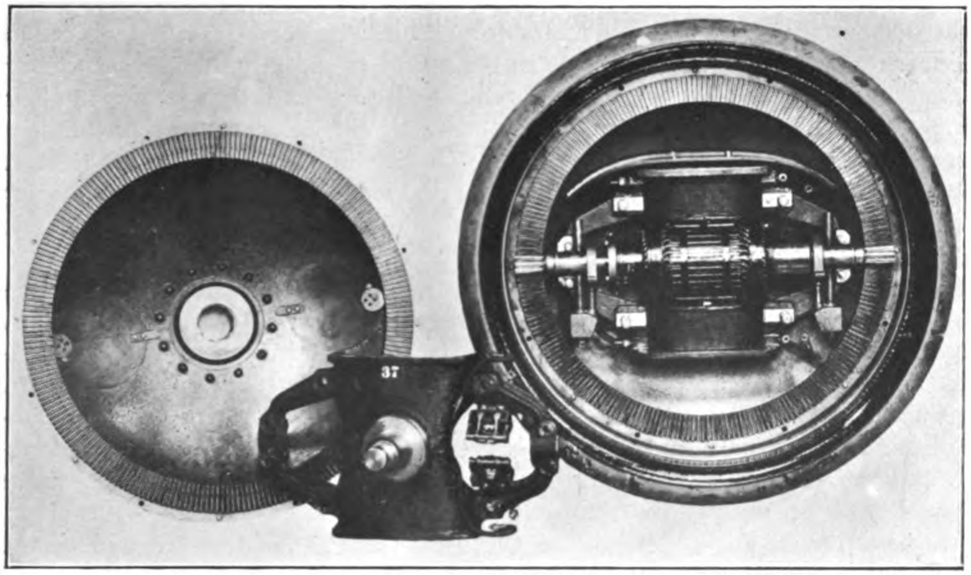
The rectangular wires or straps from which the wiring coils are formed are a high quality of copper, and these are shaped on formers so that all are uniform in size and weight, the insulating material being very carefully applied and sufficient to insure complete insulation. The windings extend beyond the core channels and are supported by the collar of the spider and the end plate, and are well protected by the five wrappings of soldered steel wire. The commutator is maintained in position by a longitudinal key. Examination of the sectional drawing will show the manner of supporting the windings, the connection of the windings and the commutator segments, the collars clamping the different elements of the armature to the spider, the keyways, the shaft and its bearings. The shaft is made from a large section of axle steel and is ground to exact dimensions, and the bearings are fitted carefully.

In the construction of the armature the design calls for a large proportion of copper, this insuring a high degree of conductivity and consequent efficiency. The core is built to have a comparatively low resistance.

The field or pole pieces are laminations of very thin sheet steel that are assembled in a registering former and are riveted under pressure, each sheet thus being in positive contact, there being no insulation of the sections. The fields are shaped with the face wider than the base, there being flanges or horns at either side which considerably increase the surface area. As will be noted from the sectional drawing the field pieces are the same length as the armature core, and each pole is retained to the seat by three cap screws seated in recesses in the motor frame. The backs of the field pieces are carefully machined to fit the contour of the seat. The pole tips are chamfered in order to regulate magnetic fringing and to reduce the noise from this cause to a minimum, but the change in the curvature is such that the pole face presents an unbroken surface to the armature core.



The Performance Curves of a Standard Westinghouse 80-Volt Motor.



The Couple-Gear Motor as Installed in a Wheel with the Outside of the Motor Case Removed, Showing the Armature, and Pole Pieces.

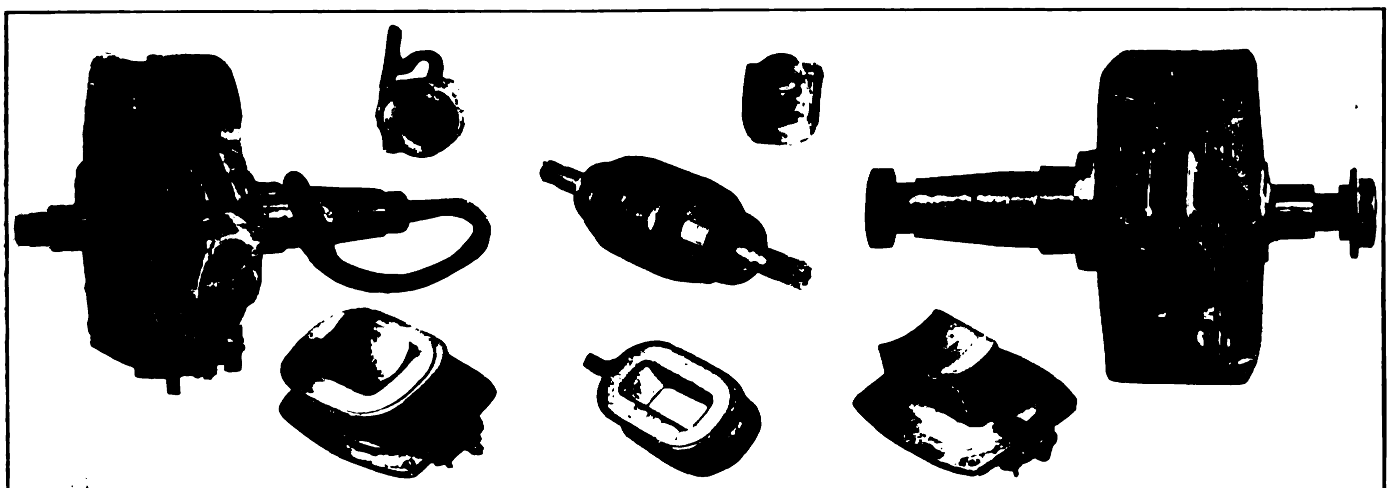
are easily accessible. The brushes are of graphite that have braided copper shunts mechanically connected with them.

In connection with the descriptions that have been made of the General Electric and the Westinghouse designs it will be noted that the former is constructed with a solid armature and the latter with what is known as the ventilated armature, there being several channels extending through the core so as to afford a greater area exposed to the air. The purpose of the ventilating channels is to secure radiation and to reduce the temperature of the armature, for heating from the electric energy is a natural consequence. Ventilation is very general in motor construction, but there is a difference of opinion with motor designers as to the value of ventilating when a motor is enclosed in a dust and water tight housing, for there is very little if any change of the air about the armature and there is not a sufficient volume to have material influence. There is no well established law governing this construction, each designer having his reasons for the particular construction which he favors.

Some of the designers maintain that the proportions of the motor, its windings and other elements govern the heating, and that this can be well controlled through this design without reference to exposure of surface area of the core, while others believe that the ventilation is an insurance that should be incorporated in the construction. Ventilated motors are generally utilized in Europe, such design being seemingly the more favored, but in America there appears to be a greater tendency to use the solid core type. As there is assurance by the manufacturers that the motors, whether or not ventilated, will meet all demands

The field coils are nearly the length of the armature windings and these are made up of a very fine grade of copper wire of rectangular section that is wound on formers or molds. The wire is wrapped with treated insulating tape and the coils are impregnated with an insulating compound. The coils are proportioned to have a large radiating surface. In the assembling a flat steel spring is placed between the coil and the pole seat, and above the coil and between it and the pole flanges is placed a flat brass shield that prevents the insulation of the coil directly contacting with the flanges. The purpose of the spring is to prevent movement of the coil either from magnetic pull or mechanical shock and the shield is to prevent wear on the insulation. In other words, this construction eliminates any possibility of abrasion of the coil and protects it fully.

The shaft is mounted on ball bearings of liberal proportions and the bearing housings are designed for the use of vaseline or any standard ball bearing grease that may be used as a lubricant. The two brush holders are a radial sliding type, accurately spaced and securely bolted to the frame, being so located that they



The Couple-Gear Motor Assembled and Removed from the Wheel, and the Armature, Pole Pieces, Field Coils and Bearings Disassembled.

legitimately made upon them, there is no need for the purchaser of a vehicle to concern himself with this detail.

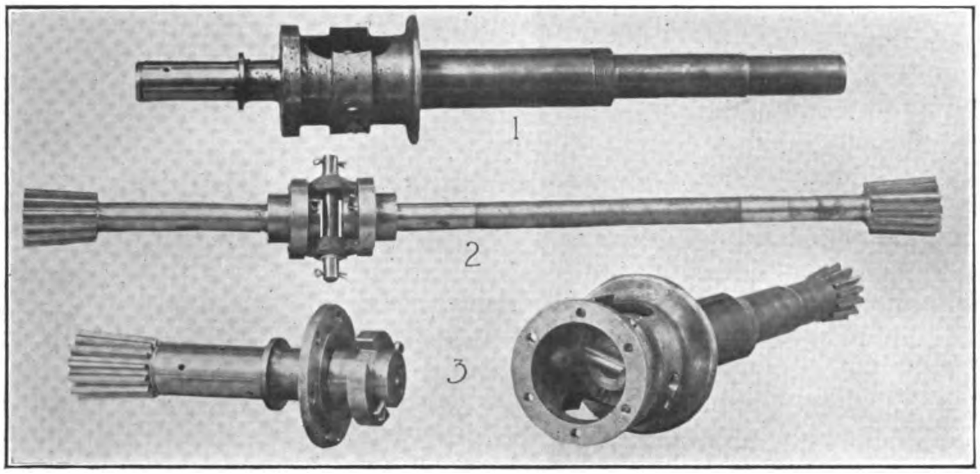
Where motors are not exposed to accumulations of dust or other abrasive substances, as are those used on vehicles, there is no cogent need of enclosing them and there is always the cooling influence of the circulation of the atmosphere. Not only this, the open motor is the more easily observed and given attention, which may be considered an advantage, yet at the other hand the enclosed motor may be run for months with practically no attention other than lubrication of the bearings at intervals of perhaps six months. Generally stationary motors have open frames and there is perfectly free circulation of air, and this is true of large generators and dynamos.

It is seldom that any other form of armature construction is used for a vehicle motor than those that have been described, and the reader may accept the two types as being almost universally adopted. As has been stated, different qualities are sought by designers and the variance while apparently very slight may produce a very important effect. For instance, the channels in the core in which the windings are laid may have a very slight variance from exact parallelism with the shaft, which is intended to minimize the noise of operation. High speed motor armatures are generally longer and smaller in diameter, the windings having greater length, this construction being regarded as being better resistant of the centrifugal force. Generally speaking, however, the core of the motor intended for the vehicle has about the same diameter as length, though this is not always found to be the case.

Taking the two designs of motors described it will be noted that there is a disposition by designers to follow with extreme care principles recognized by electrical engineers, and there is a similarity of construction that follows the application of those principles. These two concerns have standardized the vehicle motors and have carefully perfected them, but where installations vary the forms at times differ. Reference has been made to the manner of mounting the motors in the chassis, and among these can be mentioned the single motor from which the drive may be by a reduction chain to the sprocket of the jackshaft, by a shaft to the bevel gear of the jackshaft, by a reduction chain to the driving shaft, by reduction gearing to the driving shaft, by a reduction chain and reduction gearing to the differential gearing, by double reduction gearing to the wheel rims, and by a single reduction gear to the periphery of the wheel flange.

Any of the forms of motors to which reference has been made may be used for driving a machine of any size. Obviously the only moving part of the motor is the armature and the only possibility of wear is at the bearings and the commutator, but with normal attention this wear is practically negligible. The single motor may be installed in different positions, back of the jackshaft and driven by the shaft or single silent chain, forward of the jackshaft, at the forward end of the chassis, amidships or at the rear end, and either transversely or longitudinally.

With one type a motor is installed within the single front wheel, and with another the motor is contained in the housing of the rear axle.



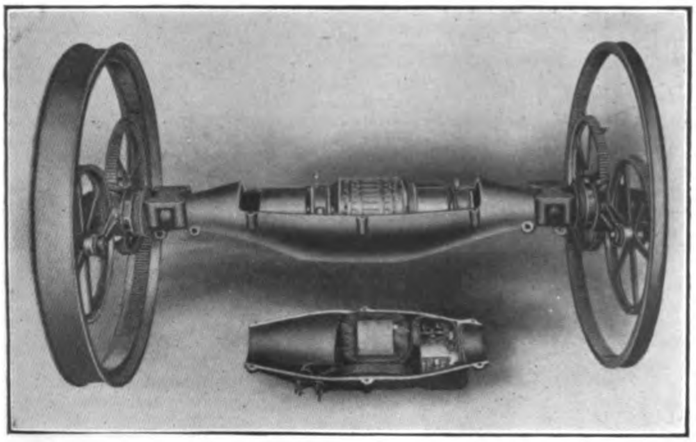
The Couple-Gear Armature Shaft and Driving Shaft: 1, the Armature Shaft or Sleeves; 2, the Driving Shafts and the "Evener"; 3, the "Evener" Separated, Showing the Pin and Connecting Bars That Serve as a Substitute for a Differential.

The design of the motor contained within the wheel is intended to simplify chassis construction and to obtain all the qualities that are desirable. It is a two-pole type and the motor is built with a long and a short shaft projecting at right angles to the armature from the frame. The long shaft is mounted in the axle and firmly fixed and the wheel revolves on it, the outer end of the axle fitting into a recess in the outer flange and affording a solid bearing. This frame contains the pole pieces and the armature, and it also supports the armature shaft bearings and the brush rigging. The armature is built to follow the principles of the General Electric and Westinghouse types, and it is assembled on a hollow steel quill or tube. The driving shaft extends through this quill and it is secured to the quill by a steel pin that is carried to short steel bars. The ends of these bars are fitted into slots in flanges or collars on the ends of the shafts, in which slots the ends of the bars may move slightly. The outer ends of the shafts carry integral pinions that mesh into the racks in the wheel flanges, and the shafts are so mounted that one pinion engages one rack and the other pinion the other rack, so that there may be a driving effort applied at either side of the wheel and with the full power of the motor. The movable bar connecting the shaft sections is known as an "evener" and it is a patented device, it taking the place of a differential gear, and while perhaps not mechanically as efficient it serves the purpose of relieving the shafts of starting stresses and has the merit of being very economical.

Were the shaft solid there would be a very severe strain when the motor was started and the evener compensates this with decided success. This is the Couple-Gear electric motor system of driving and it has been adapted to light runabouts and to heavy trucks with exceedingly practical results. The reduction in this direct drive is 24:1 for constructions intended for heavy work.

The wiring is carried through the hollow long axle stub to the motor. The brushes are mounted on the outer side of the motor frame. As will be noted in the illustration the evener is at one end of the armature shaft and the commutator at the other, and these are reached for inspection by hand holes in the outside wheel flange that are covered with large, easily removable plates.

The motor used in the machines built by the Walker Vehicle Company is contained within the housing of the rear axle, the armature being built on a hollow shaft or sleeve, into which the long driving shaft is fitted. The armature sleeve is fixed to the driving shaft. The illustration shows this construction.



The Motor of the Walker Vehicles, Which Is Placed in the Housing of the Rear Axle, with the Cover Plate Removed.

As will be noted the commutator is at the right side of the axle housing and the differential is at the other. The motor is a four-pole construction, two of the pole pieces being mounted in the lower half of the housing and the other two in the upper removable section. This cover or plate also carries the brushes.

Both the Couple-Gear and the Walker motors differ from the others in that lubricant is placed in the housing and more than the volume required for the other types of motor is used. In neither case, however, does this character of lubrication affect the motor. With the Couple-Gear motor the evener, the bearings and the pinions and racks must be supplied with grease, and the Walker motor requires grease for the motor bearings and the differential gearing.

The descriptions that have been given do not cover by any means the numerous types of motor frame construction, some of which differ materially in appearance from those described. For instance, one motor used on a well known vehicle has a frame that is literally a frame beyond the commutator end of the armature, there being four large openings that are covered with plates that may be removed by loosening a series of cap screws. Others have frames that are designed for incorporation with the axles, these having trunnions so that the motors may be swung with the forward wheels, or firmly fixed in the event of being used for rear axles. There are also the constructions in which the worm and wheel is used.

In connection with the use of any motor it should be understood that it is designed for specific work and if it is used rationally it is remarkably enduring and requires practically no marked degree of attention. But efficiency demands that there be the least ratio of frictional losses. The transmission of power has been accomplished in different ways by diffent designers, and because of the necessary speed of the armature, reduction has been made through means that have been mentioned. Though the motors may be exceedingly enduring, location where they may be reached quickly and conveniently in the event of need has been sought by many vehicle engineers, and as may be assumed the design of the motor is not dictated by the engineer, although it may be adapted to meet his requirements.

The placing the motor in the chassis may require special fitments that the greatest efficiency may be obtained, and there is no agreement as to the best type or design, for one, two and four motors, and either front or rear or all four wheels are used.

(To Be Continued.)

S. G. V. MOTOR BANK WAGON.

Bay State Trust Company Takes First of These Vehicles Delivered in Boston.

The Bay State Trust Company of Boston has purchased a motor driven bank wagon of the S. G. V. Company, Reading, Penn., maker of S. G. V. cars. It is the first machine of its kind to be supplied in Boston by the company. A stock chassis has been used and the body follows closely the lines of a small limousine. The interior is steel lined, the lining being stained the color of mahogany.

It has been a very common custom for persons having silver or other valuables to place them in storage during the summer months, when town houses are to be vacated. The Bay State Trust Company has made a specialty of this class of business and with the new car the firm is in a position to call for and deliver such valuables, taking the entire responsibility for their safety from the time they leave the owner's door until they are returned to him.

A new automobile ambulance has been placed in commission at San Jose, Cal. The chassis is that of a Haynes car, made by the Haynes Automobile Company, Kokomo, Ind., and a special body, to meet the peculiar requirements of the service, was designed according to the recommendations of several of the leading physicians of the city. Since it was put in service the machine has met all the requirements to the satisfaction of those who were interested in it.

"THE IDEAL ELECTRIC GARAGE."

THE character of garage suited for the storage of electric vehicles was considered at the concluding meeting for the season of the New York section of the Electric Vehicle Association of America, the consideration being opened by the reading of a paper on "The Ideal Electric Garage" by H. M. Martin, who is connected with the H. C. & A. I. Piercy Contracting Company of New York City. In connection with this paper was discussion of differing topics aside from the paper itself.

The paper was in part:

If one were given carte blanche to design a perfect electric garage it would seem, off hand, to be a comparatively easy matter. Doubtless many automobile problems are more difficult; yet there is much food for thought, and many compromises have to be made before the ideal design can be adapted to working conditions.

Simplicity and cleanliness are the electric's prominent characteristics, and these ideas can be exemplified in an electric garage which will be complete in every detail and yet be in strong contrast to the more elaborate equipment, and larger space necessary to garage and repair gasoline cars. Just at the present time the electrics are enjoying a certain prominence before the public, and justly so, because of the increasing cost of gasoline and the decreasing cost of charging current. As far, though, as the price of fuel is concerned, it would be well to take the utmost advantage of this situation while it lasts, since the near future will see the successful introduction of a fuel heavier even than the present liquid that is by courtesy called gasoline.

The location of the garage should be central with regard to the places of business of its customers. Since customers are not usually promised in advance, other conditions assume greater importance. If possible it should be on a well paved street near a main artery of travel, and here we strike the first necessity for compromise, since property of this description will probably be too expensive. If there is any choice in altitude the lower should be chosen—in other words, at the foot of a hill rather than at its summit. For the same reason the ground floor should be only an inch or so above the sidewalk or street level.

This brings us to the building itself. The number of floors will be determined by a compromise between the cost of ground and the cost of additional vertical construction with all that that implies—elevators, etc. Particularly if there are many floors, the elevators (of which there must be at least two) will be of as high a speed as good judgment will allow, because on the elevators' speed will depend the number of cars that can be accommodated. This is true because of the fact that in a commercial garage practically all the cars have to leave the building between 6:30 and 8 in the morning. With three men to an elevator working lively, but not to the point of danger, it takes from 20 to 30 seconds to move a car on and off. If the average floor is 60 feet from the ground floor it means that to get one car down every minute and a half the elevator must run at a speed a little better than 110 feet per minute. This is all right for small cars, but if larger ones up to five tons have to use the same elevator then an automatic device should be installed, cutting out re istance in the elevator motor's shunt field and reducing the speed to about 60 feet. In this way the apparatus itself takes care of increased load.

Electric control from the car should, of course, be employed instead of the usual hand rope. The electric control precludes the possibility of starting the elevator by anyone not on the platform itself. Automatic gates will prevent, nine times out of 10, the serious accident of having a car fall down the shaft. This usually happens when the platform has been moved without the knowledge of someone about to back a car upon it, and who sees his error too late. If the car is pushed by hand, or very slowly under power, a comparatively light barrier will stop it; but if it has attained any considerable speed it is doubtful whether any of the devices at present in use would not bend out of their guides and become useless.

It is preferable to have no posts to interfere with the free movement of cars, though to leave them out will add materially to the initial expense and make the floors thicker and the whole building higher. If posts must be used let them be spaced with regard to the number and sizes of cars that are planned to stand between them. They should be provided with base guards, which will prevent damage to projecting parts of the vehicle. Wall guards are equally important, so placed that the tires will strike them before any part of the car can hit the wall.

Concrete floors should be painted with a preparation giving them a smooth surface, which is easily cleaned and saves the concrete from wear, and gritty dust from rising. These floors should be pitched slightly from the centre line down to the side walls, both ways, with gutters formed in the concrete along the walls so that washing may be done, if necessary, without moving the cars.

Lighting should be well distributed, and each floor's lights controlled in several groups for the sake of economy of current. Around the walls, at frequent intervals, receptacles should be installed for drop cords so that these need not be of an unhandy length. The wall receptacles should be of sufficient capacity to take care of a portable drill.

Large windows are a good feature, and should be placed to allow the maximum of light and ventilation. This means a high window, which has other advantages.

The heating system should be ample to keep all floors, where cars are stored, up to at lease 60 degrees during the coldest weather. This is essential in order to start the batteries out warm. A gasoline garage can get along with any temperature above 32 degrees, but not so with the electric.

The charging equipment, switchboard, wiring, etc., should be of approved type, solid and well erected. This apparatus is so standardized that no special remarks are necessary except to suggest that rheostats, being usually grouped as closely together as their frames will permit, should be ventilated in summer. I know of a number of switchboard rooms that are intolerably hot during the warm months. In addition to this, charging plugs should be suspended in such a way that when dropped they will not strike the floor. Local conditions must decide whether, if several floors contain vehicles to be charged, one switchboard shall control them all, or whether each floor shall have a separate one.

Ventilation should also be well looked to in the battery repair room, for here batteries are often gassing for a day or more on their initial charge. The floor of this room demands special attention, acid proof brick or tiles laid in pitch being the best construction. It is of the utmost importance that the drainage system from this department—the entire distance to the sewer—should be either of lead or glazed earthenware, and preferably run as "open plumbing"—not buried in the walls.

A small machine tool equipment is a very useful adjunct in an electric garage, even where most of the work is sent out. A lathe, drill press and emery wheel will do most of the odd jobs that come up from day to day. A more complete equipment would include a shaper, milling machine and power hack saw. If the garage is to be capable of handling everything that may become necessary, it should include well equipped carpenter and paint shops. There is much to be said in favor of this, since then a car need never leave the garage except for its daily work.

Now as to management: In the first place, let there be one head to the entire system. If it is possible (and it ought to be nowadays) to combine in one person business ability and a thorough technical knowledge of the industry, then this is the desideratum. If not, then let the head be by choice a good business man, with a broad enough mind to know his limitations in other fields, and to trust his well chosen technical subordinates. Many failures in management have resulted from trouble between executives vested with co-ordinate powers; or again where large stockholders with no qualifications have held office.

From the head, direct lines of responsibility should radiate down to the most unimportant employee, so that each one shall know the scope of his work and its relation to the next move in the daily cycle of events.

There are a number of important questions that come up for decision almost daily in the operation of a garage. For instance, shall the customer be billed for accidents which may have been preventable? A chain comes off because a strut rod loosened. A controller finger burns or freezes (as the case may be) because the contact was rough. A chauffeur is arrested and fined for having no tail light—the bulb being burned out. You will note in all these cases that there is room for argument, since it is possible to say that a perfect inspection system would not have allowed the accident to occur. There are some garage managers, I am afraid, who regard such accidents as those just mentioned in the light of "Acts of Providence," especially provided to furnish them a source of revenue. In general it may be said that a public garage cannot afford to have as many really preventable accidents as a private garage can. That is, a public garage will suffer in its standing among others, and get a bad reputation if too many accidents happen. A customer whose single car is unwarrantably laid up for half a day will naturally make no end of a row about it, for, aside from the extra expense, all his plans for the day's work are upset. Perhaps I can state the case more tersely by saying that breakdowns in the case of a private garage, may, up to a certain limit, cost less than the inspection necessary to prevent them, whereas in a public garage very few strictly preventable accidents can occur without unfavorable comment and possible loss of business. This is not intended to justify preventable mishaps in either case, it is only a comparison of results. In point of fact, it takes only a very few accidents to equal the cost of a system adequate to prevent them.

At present rates charged for garaging the small cars are the ones that pay the dividends. This is not because the rates are so far from equable, but because the small car on the average does not carry so large a proportion of its possible load as does the large one. A five-ton truck is chosen and purchased for certain work because that—and often a great deal more—is the load to be transported. But the light car is bought, perhaps, to replace a horse and wagon doing odd jobs, or with the idea of being up-to-date, or again with an eye to some advertising advantage.

In dealing with the owners of commercial cars, as a rule it is only the recent purchaser who is unreasonable and not will-

ing to meet the garage management half way in the matter of disputes on bills or service rendered. A recent case is reported of a new car that ran to perfection for two weeks while operated by the factory demonstrator, and after he left was in constant trouble. The owner complained bitterly that his car was not being charged, and it was with great difficulty that he was finally convinced that the new driver was running the car with his brake set.

Another question is, just what repairs shall be included in the flat monthly rate. Minor adjustments are conceded without extra charge, but there are a number of repairs that become necessary from time to time that hardly come under this head. An owner asks to have his smashed tail light straightened out, or new licenses put on, or perhaps says, "Just lend me a bell, or a spring, or an armature (as the case may be) until mine is repaired." The "just" indicating that he does not expect to be charged for the service. Sometimes it is hard to decide just how far generosity can be stretched, but as a rule I may say that it all depends on the customer's record. Of course, old cars require a lot more in the way of incidental repairs than those of recent years, and to do any free work on them that should be charged encourages the owners in keeping them going. If I am creditably informed, there is at least one manufacturer of electric commercial cars who always scraps an old car of his own make when taken in trade, instead of giving it a coat of paint and selling it again. This policy is much to be commended, since it rids the electric vehicle world of an undesirable citizen, and raises the average efficiency of the cars that are running.

ELECTRICS IN NEW ENGLAND.

Large Increase of Registration of Vehicles During the Past 12 Months.

According to figures compiled by Business Secretary O. G. Draper of the New England section of the Electric Vehicle Association of America there has been a very large increase in number of electric vehicles registered in the different states during the year ending June 14, 1913. These include those used for pleasure and for business, and the total is well in excess of 1000. The statistics show the following:

	Passenger	Freight	Total
Connecticut	220	30	250
Maine	3	3	6
Massachusetts	497	363	860
New Hampshire	15	2	17
Rhode Island	15	8	23
Vermont	3	2	5
Totals	753	408	1161

Analyzing these figures it will be noted that Massachusetts has 74.07 per cent. of the total, Connecticut 21.53 per cent., Rhode Island 1.98 per cent., New Hampshire 1.46 per cent., and Maine and Vermont the remaining .96 per cent. Taking the passenger vehicles Massachusetts has 66 per cent., Connecticut 29.21 per cent., Rhode Island 1.99 per cent., New Hampshire 1.99 per cent., and Maine and Vermont the remaining .81 per cent. Of the freight wagons Massachusetts has 88.99 per cent., Connecticut 7.35 per cent., Rhode Island 1.97 per cent., and Maine, New Hampshire and Vermont the remaining 1.69 per cent.

The reason for the large ratio of both passenger and freight machines in Massachusetts is due to there being branches and agencies at Boston of a number of leading makes, and there is much less complete representation in the other cities of this section of the country. There is a much greater number of charging stations, the cost of current is comparatively low, and the work of the representatives has been very generally in the localities in which they are stationed. It is not too much to state that the number of branches and agencies in Boston is more than in the entire territory outside of that city. There is, moreover, more than half the population of New England in Massachusetts, and close to 60 per cent. of the population of the six states is within a radius of 60 miles from Boston.

It is a fact that the use of electric vehicles is confined to localities, generally the cities and towns in which there are charging facilities and the rates for current are reasonable. This is especially true of Hartford, where there are two exclusive electric garages, one for passenger cars and the other for wagons, and the Hartford Electric Light Company is agent for several makes of vehicle and has systematically promoted their use. This condition is true to a lesser degree in other communities, in a number of which within a comparatively short time systematic promotion has been begun, which is already producing results.

The best demonstration of the increase of electric machines is shown by the following registration figures, which are of June 14 of the present year and 1912 and are taken from the Massachusetts state records:

	1913	1912	Gain	Per Cent. Gain
Passenger	497	370	127	34.3
Freight	363	183	180	98.3
Total	860	553	307	53.7

From these figures it will be seen that the gain in passenger cars has been very large, but the increase in freight wagons has been approximately 100 per cent. This ratio is extremely interesting, for it is more than keeping pace with the gain made by any other type of motor vehicle. Last year, to Nov. 30, approximately 4000 motor wagons of all kinds were registered in Massachusetts, and of this total about 4.5 per cent. were electric. Thus far on the basis of the number of electric vehicles registered there ought to be approximately double the number of gasoline wagons to maintain the percentage of last season.

In considering the registration it should be stated that there are a number of installations of good proportions that have been planned, but the machines have not been delivered, and without much doubt at the conclusion of the official year of the Massachusetts highway commission there will be found a percentage of increase that will at least be the equal of that shown to the date named. The gain has been especially noticeable with reference to freight vehicles, and the reference made to gain has been entirely applied to this type. In the eastern part of Massachusetts, east of Worcester and including Worcester county, there are now approximately 400 passenger cars and 250 freight vehicles, a total of 650.

Two large motor 'buses capable of seating 20 persons, have been put in service at Excelsior, Mo., by Harry Silver and O. G. Pile, owners of the Day and Night garage. The machines are operated between the railroad station and the hotels and are available for picnic and outing parties. The 'buses are built on the chassis of Velie trucks, made by the Velie Motor Vehicle Company, Moline, Ill., the bodies being built by the Hess Carriage Company, Kansas City, Mo., and are giving good service.

ELECTRIC EXPRESS HAULAGE.

Development of Enormous Business Illustrated in a Motor Truck Parade.

In the recent Newark, N. J., truck parade there was a novel illustration of the development of the express business, which was originated by T. J. Hawkins, manager of the branch of the Adams Express Company in that city. This consisted at the start cf the parade of four units, the first being a man carrying a carpet bag of mammoth proportions, a replica of that with which Alvin Adams began to travel as a messenger between Providence and New York in 1840. Adams travelled by train and by steamer and carried parcels for persons who at that time desired special and quick delivery and were willing to pay for the service. The business quickly extended until it served Boston, Worcester and numerous New England cities, and when the carpet bags were no longer adequate push carts were used to collect and deliver the parcels. Later on horses and wagons were used, and these served until the development of the motor vehicle impelled the utilization of a large number of these machines by express companies.

Exhibit Made in Newark, N. J., Motor Truck Parade, Showing the Development of Express Transportation from the Carpet Bag to the Electric Wagon.

When the procession was formed the exhibition, which was intended to show the superiority of the present day equipment, was placed at the head, but before the first block of the route had been traversed the executives realized that the maximum speed of the men carrying the carpet bag and pushing the cart was so slow that the parade would be greatly delayed, so the men and their exhibits were placed in the horse wagon and carried, but it was later necessary to withdraw the animal vehicle so that the machines could move at normal pace.

Relative to the use of motor vehicles by the Adams company the first experiment was made in Jersey City about 15 years ago with several large trucks propelled by steam, but these were not found satisfactory. The first permanent installation of motor wagons was made by the company with its advent into Buffalo and Rochester, N. Y., in 1903, and since that time the use of machines has increased, there being now about 500 in the service of the company. The first order for Lansden wagons was for 25, and the second order was for 25 more for use in Philadelphia. Lansden electrics are used exclusively in Newark, the experience being that the company can do its work with fewer vehicles, though the business has been increased and the radius of operation broadened. The Lansden machine was selected because of its ease of handling, an essential factor where frequent stops and starts are necessary, and its simplicity such that the company could retain its old and experienced drivers, who were familiar with the work and the routes. The company maintains its service station and charging plant, and from carefully kept records has realized that the operating expense and upkeep cost has been considerably reduced.

The company has not been able to whittle off miles nor lengthen hours of labor and the problem has been, and no doubt always will be, how to conquer time and distance and get more work within the same number of hours. As communities expand and delivery distances become greater the company is compelled to take care of this increase without adding to the cost, as the limit of express charges has become fixed by common usage. The only way that delivery charges can move is downward, and the only manner of maintaining patronage has been by keeping abreast of requirements by the public. The use of the motor truck has been the means of meeting these new demands.

So satisfactory have been the results where installations have been made that the company's policy may now be said to place motorized equipment as needs are developed in communities of considerable size and importance.

The Luverne Automobile Manufacturing Company, Luverne, Minn., is building commercially a unit power plant that consists of a four-cylinder motor, dry multiple plate clutch, selective type sliding gear transmission gearset, fitted with carburetor, high-tension magneto and the control pedals and levers attached. These are also fitted with electric starter and generator for lighting. The plants are sold ready for installation in any type of motor vehicle.

The Cleveland Macadam Company, Cleveland, O., which operates a five-ton White dumping truck in the haulage of crushed stone, has figures that show that the truck earned $500 a month for a period of 4.5 months, when it was constantly in use, it being loaded by gravity and dumped by the power of the engine. There was a large measure of economy in quick loading and unloading.

Municipal Service Equipment

PALMER-SINGERS FOR NEWARK.

Three Brighton Six-Cylinder Roadsters for Fire Department Chiefs.

An accompanying illustration shows three Palmer-Singer Brighton six-cylinder roadsters recently furnished by the Palmer & Singer Manufacturing Company, Long Island City, N. Y., for the chiefs of the fire department in Newark, N. J. The chassis are the standard Brighton model, the principal specifications of which are: Motor, six-cylinder; bore, four inches; stroke, five inches; horsepower, 45; transmission, selective, three forward speeds and reverse; rear axle, full floating; front axle, I beam; wheels, 36 inches; spokes, 2.125 inches; tires, four inches; wheelbase, 127 inches; tread, 56 inches; gasoline capacity, 21 gallons.

One of the cars is fitted with a rumble seat, the gasoline tank being under pressure below the frame. The others have tanks above the frame, the supply being by gravity, although pressure may be used. All are equipped with electric horns, with two push buttons, one on the right of the driver's seat and the other in the floorboard, in front of the left seat.

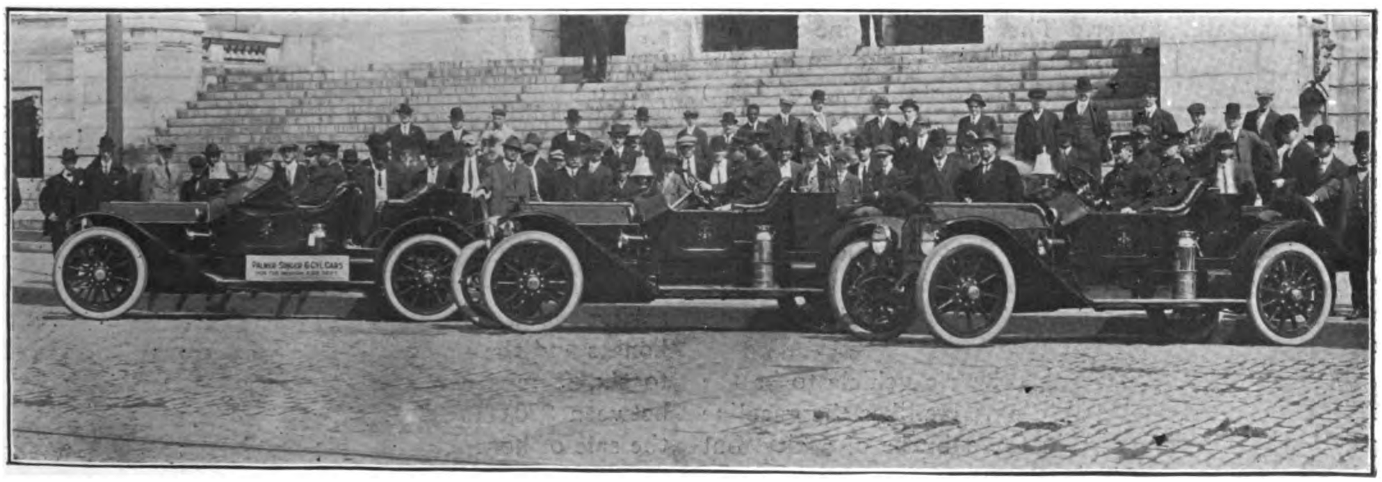
An extinguisher is carried on the left running board. A large box is securely mounted back of the front seats for boots, helmets, coats, etc. Tires are carried at the rear, Firestone demountable rims with one spare being standard equipment. An air starter is used in connection with a four-cylinder pump, clutch driven, a connection being supplied for inflating tires, cleaning motor, upholstery, etc. The lighting system is electric, the side lights having red glass and the head and tail lamps being standard. The regulation bell is securely mounted on the cowl.

SUPERIORITY OVER HORSES.

Figures of Department in Springfield, Mass., Show Economy of Motor Fire Apparatus.

No more convincing proof of the superiority of motor driven fire apparatus over horse drawn types can be cited, both with respect to efficiency in preventing fire losses as well as in the actual saving of departmental expenses, than the recent report submitted by the chief and fire commissioners of Springfield, Mass. There are now 22 pieces of motor driven apparatus in the service of the department, 80 per cent. of which are of Knox manufacture and a very interesting comparison is shown by reference to the report of five years previous, when the city had only three motor driven machines, consisting of a combination hose and chemical and two chief's cars.

The number of alarms answered by the department in 1907 was 498, with a property loss of over $535,000, while in 1912, 829 alarms were responded to, with a total loss of $166,000. It is plainly evident that the increase of motor apparatus in recent years has enabled the department to take care of a much greater number of fires with far less property loss than would have been possible with the old horse-drawn equipment.



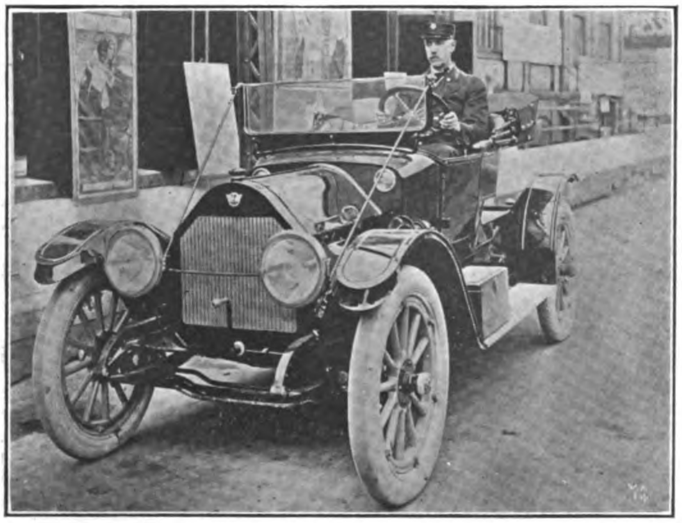
Three Palmer-Singer Brighton Six Roadsters Recently Installed with Fire Department, Newark, N. J., for Use of District Chiefs.

Further important facts are revealed as regards the saving in upkeep cost by comparing the reports of 1911 and 1912. The total expenditure for the latter year amounted to a little over $239,000, and included in addition to current running expenses were four large pieces of motor apparatus, new fire house and an increase of 32 men to the payroll. In spite of the unusual expenses and the added fact that 100 more alarms were responded to during this year than in 1911, a saving of nearly $8200 was made over the previous year's budget; surely a strong argument in favor of motor machinery from the standpoint of upkeep cost alone.

WANTS ELECTRIC TRACTORS.

Worcester Fire Chief Estimates They Would Save the City at Least $2000 Each.

Fire Chief Wesley N. Avery of Worcester, Mass., is in favor of electric motor tractors for at least three



Chief Haible of Elgin, Ill., in His Reo Roadster.

of the steam fire engines of that city and he believes that such a change would save the city approximately $6000 a year, or $2000 for each machine. The fire engines which Chief Avery would supersede with the tractors are three-horse vehicles and require a driver, engineman and stoker. The saving of one man on each machine resulting from the introduction of tractors would be $1100 for each, or a total saving of $3300 for that item alone. Estimating a cost of $300 for the maintenance of each horse, the elimination of nine horses would mean $2700, which added to $3300 would total $6000. Of course the maintenance of the motors would have to be taken into consideration, but with the saving to be gained in other ways than those mentioned to offset this, the total saving would be about $6000.

Chief Avery believes the electric vehicle to be the future machine for fire fighting. He likes the gasoline pumping engine for use in the suburbs of a city, but for the exacting work in the congested and business centres, he favors the old steam pumping engine equipped with a tractor. He maintains that the present machine does not take long to generate steam and that its dependability is a factor to be considered, while the gasoline pumping engine he claims is still far from the development it will probably later attain.

MOTOR TOWS STEAM ENGINE.

Practical Efficiency of Pope-Hartford Wagon Demonstrated at Norwich, Conn.

At a recent fire at Norwich, Conn., the Pope-Hartford combination chemical and hose wagon distinguished itself highly. The fire was on Orchard street, the highest point in that city of hills. The machine had no difficulty in climbing the hill with soft mud about six inches deep in some parts. After discharging the chemical tank it was found that a water line would have to be laid about 700 feet from the burning building.

The motor truck towed the steam fire engine, weighing 8500 pounds, a half mile to the hydrant and then made two more trips to headquarters a mile distant for hose and coke and six men. The machine climbed the hill three times with no trouble. Since it was installed a year ago it has answered 84 alarms, travelled 179 miles at a total cost of upkeep of $55.60.

DAYTON CONSIDERS AUTOMOBILES.

Safety Director Estimates That First Cost Can Be Saved in Short Time.

Safety Director A. May Dodds of Dayton, O., in response to a request from the city council, has submitted an estimate of the cost of equipping the fire department with motor driven appliances, fixing the cost at $118,450. He explained that the prices he gave in connection with the various machines were based upon what he believed to be a fair estimate of the average prices for high grade motor apparatus, but that these may be reduced slightly by competitive bidding. His figures follow:

Nine hose cars at $5250	$47,250
Two city service ladder trucks at $6000	12,000
Two 85-foot aerial trucks at $11,000	22,000
Six tractors for steam engines at $4500	27,000
One automobile for chief	3,000
Two automobiles for marshals at $1800	3,600
Two trucks for hydrant and telegraph department at $1800	3,600
Total	$118,450

Director Dodds points out that with the motor equipment the number of hose companies could be reduced from 16 to 12, which would give a larger number of men to each house than is now the case. A saving would be made in maintenance of the four houses and the number of steamers would be reduced to six, from seven. Mr. Dodds also estimates that between $20,000 and $25,000 could be obtained from the sale of horses and unnecessary equipment, and altogether, the total cost could be considerably reduced in numerous ways. In addition, the city would place

itself among the foremost cities in the country in the matter of fire fighting equipment and the cost of maintenance in a few years would pay for the total investment. It seems quite likely that the city council will decide to adopt Mr. Dodd's recommendation to completely motorize the Dayton fire department.

NEWS FROM VARIOUS CITIES.

Reo for Elgin Fire Chief—An accompanying illustration presents the 1913 Reo the Fifth roadster, made by the Reo Motor Car Company, Lansing, Mich., and used by Chief William Haible of the fire department in Elgin, Ill. Factors which determined the selection of this machine were the left side drive and centre control levers, making it possible to leave the car from either side without delay.

New Equipment in Fall River—A KisselKar double tank machine and a Pope-Hartford single tank car have been ordered by the fire commissioners of Fall River, Mass.

Des Moines to Motorize Department—Councilman Van Liew recently submitted a plan to the city council of Des Moines, Ia., for completely motorizing the fire department of the city, which provided for the purchase of nine combination hose and chemical trucks, four hook and ladder trucks, one tractor and three combination hose and pumping trucks, at a total cost of $102,464.

In the Market—The following cities are considering the purchase of motor fire apparatus: Oswego, N. Y.; Fort Dodge, Ia.; New Bedford, Mass.; Buffalo, N. Y.; Healdsburg, Cal.; Taunton, Mass.; Reading, Penn.; Lewiston, Mont.; Tropico, Cal.; Manchester, N. H.; Jacksonville, Fla.; Kansas City, Mo.; Lockport, N. Y.; Ironwood, Mich.; The Dalles, Ore.; Corning, N. Y.; Greenville, O.; Benson, Neb.; Springfield, Ill.

Springfield, Mo., Adds Five Pieces—Springfield, Mo., recently placed in service a gasoline pumping engine, two motor hose wagons and a chemical engine, made by the American-La France Fire Engine Company, Elmira, N. Y., and a combination hose and chemical wagon, manufactured by the Anderson Fire Equipment Company, Kansas City, Kan. Together with the new fire alarm system, Springfield is well fortified to guard against serious fires.

Pope-Hartford Tractor Orders—The city of Brockton, Mass., has signed a contract with the Pope Manufacturing Company, Hartford, Conn., maker of Pope-Hartford fire trucks, for three combination hose and chemical wagons and a four-wheel tractor to replace a triple-hitch of horses on the hook and ladder truck at central station. The combination machines cost $5500 each, while the tractor is $4900, making a total of $21,400 for the equipment.

Federal Replaces Five Horses—A 1.5-ton Federal truck, made by the Federal Motor Truck Company, Detroit, has recently been placed in the service of the meter division of the water department of St. Louis, Mo. The overhead design is of special interest in that the quick loading and unloading of half-ton meters can be accomplished by the driver alone. The truck covers a route of 15 to 30 miles a day in transferring the men from one job to another. To date the data show that a crew of six men, divided into pairs, do the work of five single-horse wagons with 10 men.

Montreal Divides Between Two Concerns—Montreal, Can., recently appropriated funds and awarded the contract for eight high powered automobiles for the use of the deputy fire chiefs of the city. The award of the contract was a very unusual one, as it was divided equally between two competing automobile companies, although the entire eight cars are to be used for practically the same purpose and meet substantially the same specifications. The Cadillac Motor Car Company, Detroit, was awarded the contract for four, while the other four were awarded to the Abbott Motor Company of Detroit. Both concerns have cars in the service in Montreal and have made preliminary tests to the satisfaction of the city officials.

To Supply All Departments—In the recent appropriation bill submitted to the city council of St. Louis, Mo., provision is made for the purchase of 19 automobiles for the use of various city officials. The cost of them will be $24,000, as follows: Street department, touring car for commissioner, $2400, and four runabouts, $2400; commissioner of supplies, automobile, $1500; city lighting department, three runabouts, $1800; fire department, automobile supply truck, $3000; fire and police telegraph automobile, $2500; sanitary division, health department, two runabouts, $1100; city forester, runabout, $1000; hospital department, city dispensary, two automobile ambulances, $6000; industrial school, automobile, $1000; assessor and collector of water taxes, two runabouts, $1200.

Chelsea Secures Powerful Engine—Chelsea, Mass., which five years ago was nearly wiped out by a conflagration, has put in service what is claimed at present to be the most powerful fire engine in the world. It is known as a triple combination gasoline pumping engine and cost $10,000. The machine is capable of travelling at a mile a minute, throwing four streams of water, twice the number of the ordinary fire engine, and pumping 1200 gallons of water a minute, equal to two steam engines. In addition it is a chemical engine and hose cart, carrying 1200 feet of hose, and is equipped with two 25-foot ladders. In other words, with its crew of five picked men, it is a modern fire department all by itself. The tests of the machine demonstrated its capabilities to answer to all claims made by the maker, the Robinson Fire Apparatus Company, St. Louis, Mo.

MACK TRUCK IN HEAVY WORK.

Maintenance Figures Supplied by Structural Iron and Steel Contractor in Philadelphia.

The transportation of structural iron and steel is a heavy duty service which imposes very hard usage on any kind of vehicle and causes exceptional strains on the entire chassis. The five-ton Mack truck, made by the International Motor Company, New York City, in the service of the H. T. Potts Company of Philadelphia, has given excellent satisfaction in this field.

The Potts company is contractor in structural iron and steel material which is delivered to the builders throughout Pennsylvania and New Jersey. The average daily performance of 26 miles indicates the general conditions under which the loads are transported. H. T. Potts, superintendent of transportation of the company, has kept a carefully compiled record of the Mack truck since Aug. 14, 1911, to March 31, 1913. In that time the total disbursements for all purposes were $1985.37. This figure includes every expense—driver's wages, insurance, etc.—with the exception of depreciation and interest.

The total tire cost in the above period was $765.94, but an expense of $115.25 was incurred when the vehicle was painted and alterations were made. Included in the outlay was $85.36 for a speed and mileage recorder. Pennsylvania and New Jersey licenses for the vehicle and driver amounted to $123, $41 a year. Eliminating these items from the gross expenses, the maintenance cost amounts to $985.87. The tire expense, adding the value of the original tires, the item noted above, works out at .0096 a mile.

During this period the working days for the truck numbered 407; total mileage, 12,220; cost a mile for tires, including tires supplied with truck, 9.56 cents; operating costs a day less the tires and driver, $7.30. This includes gasoline, repairs, supplies, oils and greases, renewal of parts, etc. In all the 407 working days the truck was actually out of commission only six days, not including the time it was voluntarily laid up for painting.

The Watson Contracting Company, New York City, specializes in street grading and naturally the one big item of expense is the cost of hauling heavy building materials from the water front to the location of the different jobs. Previous to 1912 the company used horses exclusively for all its hauling. As an experiment it purchased two Garford trucks, made by the Garford Company, Elyria, O., and kept a careful check on the amount of work they could do, together with upkeep costs as compared to that of horses. The economy and all around efficiency was so apparent that today the concern has in operation a fleet of 18 Garford machines. Mr. Baisley, a member of the firm, claims that one of these will do the work of at least nine of its best horses and that as many as 44 horses have been sold at one time since the Garford machines were installed.

WILCOX SAVES THE BUSINESS.

Transfer Man Enabled to Make a Profit After Failure with Horse Drawn Equipment.

A lesson in the value of the motor truck might be learned from the experience of Charles Martin of Germantown, Penn. He went into the transfer business five years ago on a fairly ambitious scale, with seven horses, three wagons and three drivers. The average price of his horses was $150. Business came quickly and there were prospects of good profits when his horses began to fail. His Germantown run was long and hilly and the journey consumed so much time that the horses had to be fed en route, with the result that they developed colic and indigestion. Eleven horses died in 10 months. Five more went in the second year, making a total loss of $2400, for the prohibitive rate on horses had put adequate insurance out of the question.

Martin faced ruin, having lost his entire investment. He was about to seek another means of livelihood when it occurred to him to purchase a motor truck. This was a daring project, for $3000 looked big to him at that time. But his logic was sound. He had the business and all he needed was a medium of delivery. If he could eliminate the horse and secure something that would not sicken and die, he could operate at a profit.

He purchased a 1.5-ton Wilcox, made by the H. E. Wilcox Motor Car Company, Minneapolis, Minn., and it replaced seven horses and three drivers, for it was found to be able to do all the work of collecting from the manufacturers in Germantown and vicinity, articles to be taken into the centre of the city and the wharves for shipment by various steamship lines. On the return trip supplies are distributed to drug stores. These goods are the products of wholesalers in the centre of the city. Martin did all his own driving in order to aid his policy of retrenchment. The truck moved so quickly that it covered the whole route and by 8 in the evening was back in the garage ready for any profitable night work which offered. At reasonable rates he was able to carry four kinds of insurance —property damage, liability, fire and collision. This eliminated any risk. That was a year ago. In the interval the truck has paid for itself and declared a substantial profit for its owner.

A one-ton Kelly, made by the Kelly-Springfield Motor Truck Company, Springfield, O., is saving $50 a week for the Coca Cola Bottling Company, Rome, Ga., according to F. S. Birem, manager of the company. This saving is made in livery and hotel bills. Before the purchase of the truck some of the hauls by wagon took two days, and it was necessary to pay hotel and livery bills two or three nights a week for two teams and two drivers. The Kelly makes these hauls in less than a day, averaging from 75 to 100 miles a day for six days.

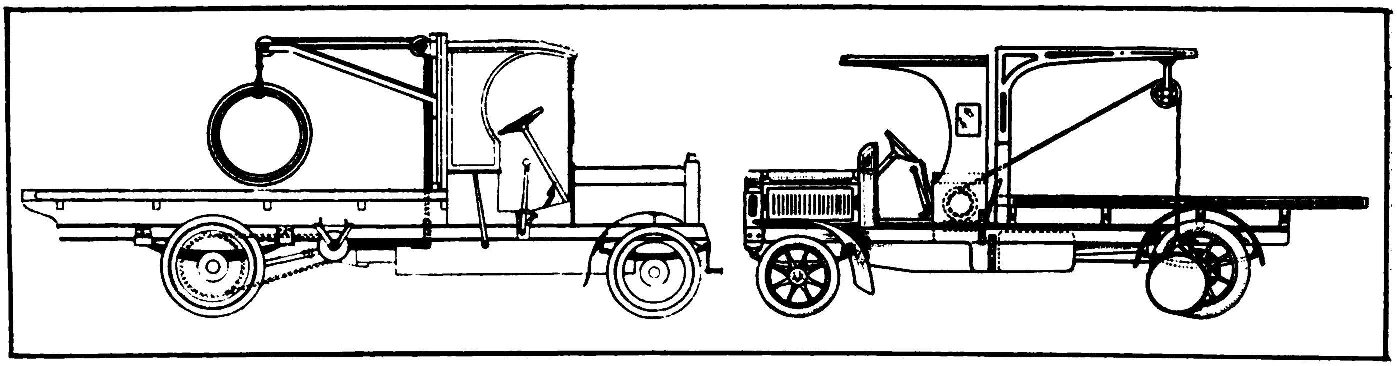
FOREIGN TRUCK NOTES OF INTEREST

CONCERNING LOADING DEVICES.

Some Suggestions That Make Their Appeal to British Motor Truck Users.

Attention has been drawn a number of times recently to the discussion of quick loading and unloading devices which is now occupying the minds of British motor truck users. This is brought out very forcibly in a recent number of The Commercial Motor of Great Britain, which states that it has been confronted of late by a large number of inquiries concerning power driven loading devices from users whose loads consist of casks or similar bulks.

An accompanying sketch presents two such arrangements fitted by British manufacturers. That adopted by the maker of the Karrier wagon has the winding drums placed at the side of the chassis frame members in such position as to allow the hauling ropes to be taken either to a jib arrangement mounted over the platform, or by way of leads to lower barrels of beer, etc., into a cellar or to hoist them onto a loading platform. It is intimated that the actual arrangement of the gearing is a question for the designer, and it is held that this involves no question of serious moment.



Suggested Easy Loading Devices for British Brewery Truck Users: At Left, Power Hoisting Arrangement on Leyland Vehicles; at Right, Patented Hoisting Gear on Karrier Wagons.

The plan adopted by the Leyland Company is a variation of the Karrier patented device and is even more fully set forth in the drawing. This company also has a small jib crane fixed on the platform and provided with a swivel accommodating an ordinary pulley block, the drums in this case being designed to be operated by hand.

MOTOR TRUCKS IN BRAZIL.

Consul-General Lay Gives Advice Respecting the Correct Procedure in This Market.

According to Consul-General Julius G. Lay of Rio de Janeiro, Brazil, more American automobiles, and particularly motor trucks, would be sold in that country if manufacturers would establish agencies where spare parts and cars could be kept in stock. An American using trucks informed Consul Lay that he did not buy his machines in the United States, although they were better suited to his purpose and more reasonable in price, because he could not wait for parts from this country, and he therefore purchased a German truck, sold by an agent carrying a full line of spare equipment.

There is an increasing demand in Rio de Janeiro, which has a population of nearly 1,000,000, and in other large ports of Brazil for American trucks. The streets of Rio de Janeiro are paved with asphalt for many miles, the distances are great and the traffic heavy. Mr. Lay believes that American motor vehicle manufacturers cannot expect to secure even a small share of this trade by arranging agency contracts through correspondence and advertising their goods by catalogues. The only way, in his opinion, to establish satisfactory connections and secure a firm footing in that market is to send there a competent representative with one or two sample cars, prepared to remain several months to assist his agent in demonstrating and advertising the machines.

GERMANY'S MOTOR CREMATORIES.

Automobile Equipment to Be Used in the Future in Disposing of Battle's Dead.

After thousands of years of being buried with honors on the field of battle, soldiers in the future will be incinerated in portable crematories mounted on motor trucks. At least this is the plan of the German general staff, following the report submitted to it by an army surgeon who accompanied the Bulgarian army and who witnessed the various assaults on Adrianople.

He reported that had it not been for the cold weather, which prevented the bodies from decaying on the battlefield, the vapors arising from them would

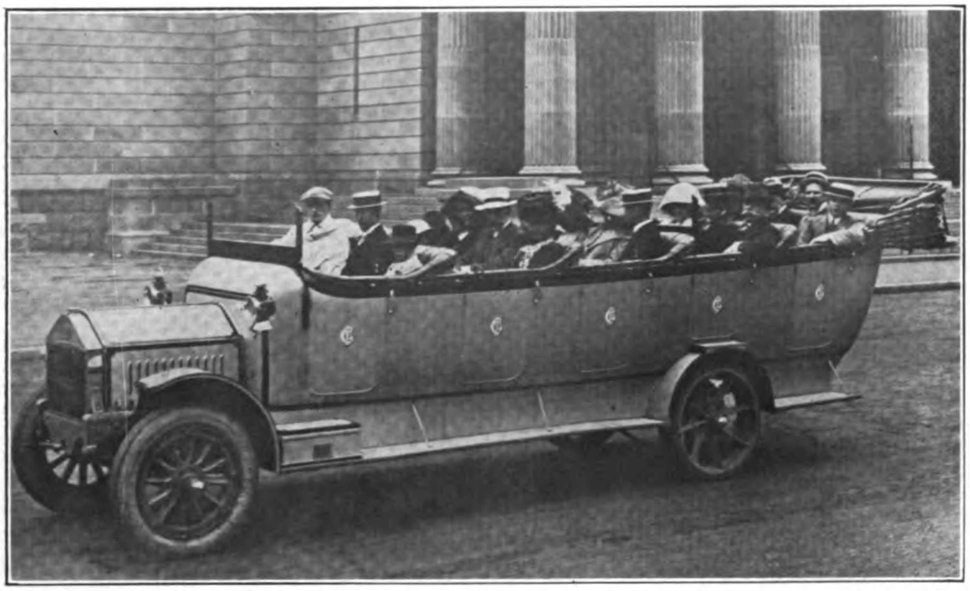
have caused disease, with untold results among the survivors. In the future this contingency will be met by the use of motor crematories, capable of incinerating at one operation from 10 to 25 bodies and able in the entire 24 hours of each day to dispose of from 300 to 500.

AGAIN THE CHAR-A-BANC.

British Engineers Enthusiastic Over Its Possibilities in This Country.

Among the suggestions offered by the party of British engineers during the recent American tour was that of the possibilities of the char-a-banc in this country. Several of the visitors were very enthusiastic with respect to the matter.

An accompanying illustration shows a Lacre char-a-banc of the so-called torpedo type, designed to accommodate 20 passengers. These vehicles are used in



Thirty Horsepower, 20 Passenger Char-A-Banc of the Torpedo Type, Manufactured by the Lacre Motor Car Company.

Great Britain in many of the country towns and the suburbs of cities under conditions where it would be expected that short trolley lines would be operated in this country. In England they have been found a decidedly paying proposition, as may be gained from the knowledge that the cars are splendidly upholstered and the appointments are much more elaborate than the so-called motor 'buses sometimes utilized in America.

The chief advantage claimed for the vehicles, in catering to the convenience of the public, is that they draw up to the curb to take on and deposit a fare, thereby obviating the necessity for the passenger to cross a portion of the roadway, as with the trolley service. In both England and France, where these cars are operated in large numbers, it has been found that the public is very liberal in its patronage, char-a-bancs being hailed for a short trip of half a dozen blocks instead of the patron attempting to walk the distance.

The opinion expressed by the visiting engineers was that within a few years many of these vehicles would be in operation in America and that they would be found to present a business proposition in every way as successful as they now are abroad.

PERUVIANS TESTING TRACTOR.

Government Officials and Prominent Citizens Interested in Demonstration of American Product.

Recently a demonstration of an American traction engine was made in the suburbs of Lima, Peru. A special train was run to the field at the expense of the local manager, Fernando Ortiz de Zevallos. About 100 of the most prominent owners of estates in Peru were present, also the minister of public works and development, director of irrigation and agriculture and other officials of the government, as well as the principal officers of the American legation in Lima and the consulate at Callao.

The object of the demonstration was to place on record the facts relative to the possibilities of traction engines in Peru for cultivation methods. The exhibition lasted the entire day and the spectators seemed well pleased with the deep plowing possibilities and the complete success of the machine in turning over the surface of an old field formerly planted in cane and still covered with roots, which hitherto always had to be burned out. Although there have been several British and other foreign machines imported to Peru, this is the first American tractor of its kind that is known to have been used in the South American republic.

AUSTRIAN WAR VEHICLES.

Government Is Now in the Market for 200 Machines with Full Military Equipment.

Austria, through its war office, recently placed orders with the four local automobile factories at Prague for 25 to 30 trucks and trailers, each truck having a capacity of 10 tons, the price paid for each machine and trailer being $5380. The same trucks are sold to firms or individuals for $3350, and when thus sold to private purchasers the government pays the factory a subsidy of $2030 for each truck. The government keeps a record of all these vehicles and in the event of war they are taken at an appraised valuation. They must also be placed at the disposal of the government for 14 days each year, during military practise, for

which service the owner is to receive $8.12 a day.

The government is also in the market for trucks of the second class, or light vehicles, up to 200 in number. They must be capable of carrying from 2,000 pounds to two tons at a speed equal to that of the heavier cars. Both classes must be able to ascend a gradient of one in 10 on bad roads. The specifications are furnished with each class. The second schedule calls for searchlight trains up to 50 sets. Each is to consist of a light motor chassis with a 25 to 40 horsepower engine, and a 10 to 15 kilowatt dynamo for the searchlight; a trailer with one searchlight of 90 millimeters or more fixed on the car, or with two portable searchlights or about 60 millimeters, with a cable drum and 200 or 300 yards of cable.

HIGHWAY CONSTRUCTION IN CHINA.

Native Engineers Engaged in Laying Out New Road for Motor Truck Service.

Chinese engineers, under the direction of Jick G. Wong, an American trained engineer, have been at Hong Kong, China, making arrangements for commencing the survey of an automobile truck road in Kwangtung province, which is designated as a feeder for the Kwangtung section of the Canton-Hankow railroad. The road now planned and for which detailed surveys are being made, will be about 100 miles long.

It is expected to start at a station called Po-Ko, about 70 miles from Canton, and will follow the line of the old imperial mail and courier road or path, a way over which imperial dispatches have been transported for hundreds of years by relays much in the manner of the old pony express in the West of the United States. It is planned to give the new road considerable hard surface dressing and to build substantial bridges. No decision has been given yet as to motor trucks to be used. The company behind the project is composed of Chinese capitalists.

EASTBOURNE'S MOTOR OMNIBUSES.

Official Report Shows Department Is Being Placed on Satisfactory Efficiency Basis.

The annual report of the Motor Omnibus department at Eastbourne, England, is of considerable interest, inasmuch as Eastbourne originated 10 years ago the municipal carrying of passengers by motor 'buses. P. Ellison, general manager and chief engineer of the company, reports that for the year ending March 31, 1913, the department showed a net profit of over $3500, which is the highest net earning recorded during the life of the undertaking. The gross profit for the year was about $18,500, but of this about $15,000 was paid out for interest and repayment of loans.

In spite of the excellent showing, it is brought out that owing to weather conditions the number of passengers carried decreased some 30,000 over the previous year, requiring a smaller number of vehicles, this reducing the total mileage for the year by 6740 miles. The number of passengers carried a mile, however, increased from 11.12 to 11.32, while the cost of operation remain stationary. The figures for repairs and maintenance show a marked decrease over the preceding year. That the operation of the various motor lines is to be placed upon a better basis of efficiency is apparent.

GENERAL NEWS FROM ABROAD.

Great Britain Buys Military Trucks—As a result of the recent qualifying trials, the British war office has purchased 15 three-ton trucks of John I. Thorneycroft, Ltd.

Hungarian Plowing Competition—An international competition of motor plows is to be held at Galanta, Hungary, in July and August, under the direction of the Hungarian Agricultural Society of Budapest.

Wants Agrimotor Agency—A representative of a large and well established concern in Australia was in England recently to secure the agency for agricultural motors in that section. It is stated that the possibilities for this class of vehicles are decidedly good.

Russian Mail Service—A motor mail and passenger service has been organized in Siberia, Russia, on the route from Verkneaudinsk and Troitskosavsk, in the province of Transdaikale. The length of the route is 215 versts and the service runs once a day in either direction, the fare charged being between 21 and 22 roubles a passenger.

British Imperial Conference—A large number of delegates representing the varied business interests in the various colonies and dependencies of the British empire will be present at the imperial motor transport conference to open July 18. From even remote places delegates are assigned and the coming conference promises to be of great importance and a wonderful stimulus to the motor truck industry.

Testing Kerosene Carburetor—Under the open competition rules of the Royal Automobile Club, England, a road test of 1000 miles was recently made with a 20 horsepower Ford car, fitted with a Standard kerosene carburetor. The trial was made on the club's six standard routes and the distance was covered at an average speed of 19.91 miles an hour. On 10 occasions after short stops the engine was started on kerosene; at other times the gasoline carburetor was used for starting. The amount of kerosene used was 30.28 gallons, representing a consumption of 33.03 miles a gallon, or 35.69 ton-miles a gallon. For starting purposes 1.69 gallons of gasoline were used.

New Commercial Car Accessories

Eiker Carburetor.

One of the features of the Eiker carburetor, manufactured by the Eiker Carburetor Company, 1790 Broadway, New York City, is that the spray nozzle is located in the middle of the throttle disc and a tapered adjustable needle valve moves backward and forward, automatically increasing or decreasing the supply of fuel with the opening and closing, respectively, of the throttle. The maker holds that this construction eliminates the necessity of a venturi tube or extra jets. It has but one air inlet. It is pointed out that water or sediment in the fuel cannot clog the spraying nozzle as the feed pipe is well below the level of the gasoline. The base, which includes the auxiliary a'r valve, air intake and hot air connection, adapts itself to four different positions, making for convenience in installation. There are but two adjustments, the fuel and the air. Easy starting, economy of fuel and flexibility are emphasized with the Eiker.

Apco Master Vibrator.

The Auto Parts Company, Providence, R. I., is marketing a new master vibrator for model T Ford cars termed the No. 3. The new coil is but 1.5 inches thick, 3.5 wide and five high—dimensions permitting of installation under the hood if desired. The case is of mahogany, nicely finished, and the removable cover is accurately fitted, excluding dirt, etc. All exterior components, such as parts, terminals, etc., are heavily nickel plated. The adjusting screw of the vibrator includes a special locking device, and the contact points are unusually large, insuring long life with minimum care. Particular attention has been paid to the windings and these are designed to withstand high voltages. Although the Apco vibrator is moderately priced the best of workmanship and material are incorporated.

Regent Breast Drill-Valve Grinder.

P. G. H. Bennett & Co., Lansdowne street, Fenway, Boston, is marketing the Regent breast drill and valve grinder, a combination tool. It is furnished with a Star expansion chuck taking drills up to .25 inch, a screw driver blade for slotted valve heads and screws, four spanner tools to fit different makes of cars, and a coil spring. The last named is fitted under the valve when grinding. One of the features of the tool is that it may be changed easily and quickly from a breast drill to a valve grinder or vice versa, by a simple movement of the index finger. This is accomplished by actuating a shifting finger or trigger. By utilizing this member when grinding valves the motion can be changed instantly to a reciprocating one of about 45 degrees. The best of material and workmanship are incorporated in the tool.

Invincible Blow-Out Patch.

The Invincible blow-out patch, made by the Invincible Tire Company, 53 Sabin street, Providence, R. I., maker of the Invincible tire, differs from the usual patches in that in addition to the conventional fabric there are two layers of chrome leather. These are inserted between the layers of fabric, and being very pliable conform readily to the shape of the casing when inserted. This construction makes the patch puncture proof. One side of the outer fabric is coated with pure para gum, protected from dirt, etc., by a holland cover. When use of the patch is desired the cover is stripped and the gum surface moistened with gasoline. This side is applied to the interior of the casing and being self-vulcanizing it is impossible for the patch to creep or slip. With the Invincible the use of an outside sleeve is not necessary as the chrome leather reinforces the construction. It can be utilized over and over again.

McNutt Automatic Closing Can.

The McNutt Non-Explosive Can Company, 352 Pearl street, New York City, is manufacturing the McNutt automatic closing can, which is produced in five and 10-gallon types. They are equipped with the McNutt safety device, which is also utilized in fuel tanks of all dimensions and which has been indorsed by the fire department of New York City. The device sounds a warning, as soon as a dangerous pressure occurs, by making a loud whistling noise, and a safety valve releases the pressure. The screw cap is provided with a fusible disc valve, which, when the container is subjected to contact with fire, will give vent to the pressure, thus preventing explosion. The valve seat will melt at 300 degrees Fahrenheit, and the entire valve will blow out, leaving a clear opening and preventing bursting of the container. Further protection is afforded by a fire screen located at the bottom of the device, it preventing the flame back-drafting into the tank. The safety screw cap is provided with a check valve for gravity systems, preventing vapors from leaving the tank, but permitting air to break the vacuum. The McNutt cans are constructed of high grade material and are designed to withstand severe service. The company also manufactures self-closing cans.

Heco Magneto.

The Heinze Electric Company, Lowell, Mass., is producing the Heco magneto, which differs from the usual types in that round magnets are employed, the company maintaining that greater efficiency is secured through a positive contact with the hole pieces. The make and break case is constructed of steel tubing with fibre insulation, the latter being shrunk onto the outside. The cover is removable without tools. The distributor case is of hard vulcanized rubber and the terminals are of the detachable type. The instrument is termed a low-tension in that the low voltage is stepped-up by a coil having primary and secondary windings. The current is distributed to the plugs by the magneto. The dash coil is of mahogany, and is equipped with a kick switch and push button for starting purposes. The Heco is constructed for one, two, four and six-cylinder motors, and owing to the special method of winding of the secondaries is guaranteed against burning out or breaking down.

Excel Auto Jack.

An auto jack that presents practical and interesting features is the Excel, marketed by the Excel Auto Jack Manufacturing Company, 27 Lansdowne street, Fenway, Boston. It is designed for both the repair shop and service station, is rapid and positive in its action, occupies but little room and is a time saver in that it can be operated without stooping or risk to the user. It is provided with a swivel to permit of its use at any angle, and a toe is included for service where the top piece is too high. The initial adjustment is instantaneous and the jack has a lifting capacity of 6000 pounds. Its height when raised is 25 inches, when closed nine, and the weight 25 pounds. It is made of steel, the housing being cast steel and the lever a steel forging. The carriage is mounted on rollers, making for convenience, and the jack lifts from either hub or axle.

THE A B C OF MOTOR TRUCK IGNITION.

Part XI—Explaining the Operation of a Dynamo and How a Direct Current Is Obtained—Construction of Interrupter or Make and Break Mechanism Utilized for Breaking Primary Current of Magneto.

By C. P. Shattuck.

REFERENCE has been made to the dynamo or generator and it was pointed out that it differs from the magneto in that electro-magnets are em-

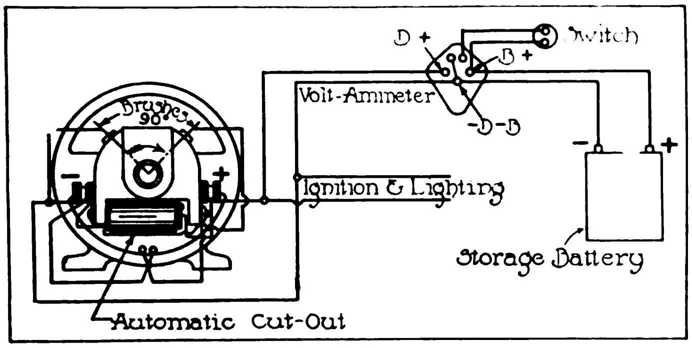

Fig. 54—The Apleo Dynamo Supplying Current to Storage Battery Which Is Floated on the Line—All Electricity for Ignition or Lighting Is Drawn from the Cells.

ployed insead of permanent. An electro-magnet is constructed by inserting a bar of soft iron, wrought or cast, within a coil of insulated wire, preferably copper, on account of its high conductivity. By passing a current through the wire coiled about the iron core, the latter becomes magnetic, attracting iron and steel bodies, and in general exerting an observable effect upon any polarized conductor, such as a solenoid. As soon as the current is cut off the iron core loses its magnetic properties. If a core of hardened steel be substituted for the iron and a strong current be sent through the wire, the metal will become a permanent magnet, retaining its characteristic magnetic effects for a practically indefinite period.

A bar of iron or steel thus temporarily or permanently magnetized invariably shows the phenomenon of polarity, the poles always being determined as positive and negative by the points of the inlet or exit of the current, as in solenoids. The magnet can also induce a momentary current in a closed circuit of wire and in a similar manner to ordinary current induction.

It has been pointed out that the theory of electrical generation by mechanical means is that the lines of force of a magnet should be cut through, so that their strength and direction at any point or at any time should be made to vary constantly. In addition, it is necessary that there should be some means of collecting the current, resulting from the continual disturbance of the magnetic field, and supplying it to a circuit.

The wiring plan of a dynamo is presented at Fig. 55 with the components designated. It will be noted that the armature core differs from that of the magneto; that the windings are dissimiliar, and that the armature rotates upon the longitudinal centre line of its core. The armature carries a large number of coils of wire placed in planes which pass through the longitudinal centre line of the core. At the end of the core is a collector or commutator from which the current generated by the revolving of the armature is collected by brushes and led to the outside circuit. The commutator also serves to cause the current to flow continuously in one direction—or a direct current—as without this member the electricity generated would be alternating.

The generation of current, therefore, is by rotating the armature between the pole shoes, etc., and the faster the core is revolved the stronger is the current because the strength of the magnetic field is increased, due to the greater amount of current being delivered to the field coils. It is obvious that the dynamo is an excellent source of electricity when driven at a constant speed, but because of the need for regulating it, either by governors or electrically, the magneto is favored for ignition purposes as it may be driven at variable speed.

The dynamo or generator is now generally utilized for lighting on pleasure cars and a few commercial vehicles, the variable speed of the gasoline motor being compensated for by friction clutches, governors, electric controls, etc., and with several systems the storage battery charged by the dynamo is employed for ignition purposes as well. The use of a dynamo on the automobile is not new, the Apple Electric Company of Dayton, O., having marketed an ignition dynamo several years ago, a number of which machines are in service today. The battery is floated on the

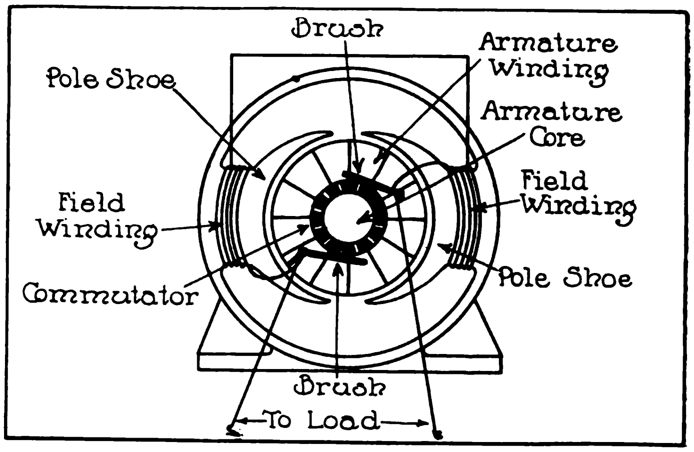

Fig. 55—Illustrating the Components of a Dynamo or Generator and How Direct Current Is Obtained.

line, the current from the generator being utilized to keep the cells in a fully charged condition. As will be noted by Fig. 54, which shows the wiring plan of an

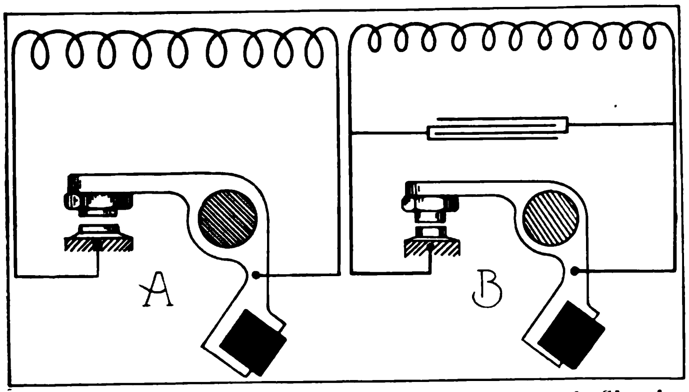

Fig. 56—Make and Break Mechanism of Magneto: A, Showing How the Primary Circuit Is Broken; B, Illustrating Use of Condenser, Employed to Prevent Burning of Platinum Contact Points.

Aplco dynamo, the electricity for either ignition or lighting, or both, is drawn from the battery. In the machine illustrated an automatic cut-out is employed to prevent the battery discharging through the generator when the voltage of the latter falls below that of the cells, which occurs when the armature is rotating slowly. The cut-out also is utilized to connect the generator to the cells when the proper charging value is obtained in the dynamo. The current is direct as an alternating one cannot be employed in charging batteries unless converted by a rectifier or other suitable device.

The current generated by dynamos is low-tension, and when employed for jump spark ignition purposes must be stepped-up or transformed by an induction coil. The process is identical with that of the battery and coil system previously explained.

Interruption of Primary Circuit.

In the previous chapter it was explained how current was induced in the windings of the H or shuttle type of armature and that the action occurred twice in each complete revolution of the armature. It was also shown that this primary current attained its highest efficiency or strength when the armature was in a certain position and that the nature of the current was alternating.

Irrespective of whether the instrument be a low-tension or a true high-tension, it is essential that the flow of the primary current be broken or interrupted just as it is with the commutator or timer utilized in the battery and induction coil system of jump spark ignition. For this purpose an interrupter or mechanical breaker is employed.

The simplest form of the make and break mechanism consists of two points to which the ends of the primary circuit of the magneto are connected. The drawing at Fig. 56 A shows these members with the positive and negative wires connected. With the two points in contact it is evident that the circuit is closed and that current is flowing. Upon separating the points the circuit is broken. The operation is very simple, and the circuit breaker or interrupter may be termed a switch.

Components of Breaker Device.

At Fig. 57 are shown views of the Bosch interrupter mechanism, that at A being a front view, while that at B is the rear construction. The components are lettered and it will be seen that the actuating parts are mounted on a metal disc, usually bronze or brass, bored and provided with a keyway for fastening securely to the armature shaft. The disc is further secured by an insulated screw which also serves to conduct the primary circuit to the contact piece. The latter is insulated from the metal disc by mica or other suitable material and the screw shown by the shaded lines in the sketch is also insulated. The contact block carries an adjustable screw retained in a predetermined position by a lock nut. The tip of the screw is fitted with a small hexagonal nut in which is imbedded a platinum point. The interrupter lever, which is pivotally mounted, carries a similar nut and platinum point, and a semi-circular spring tends to keep the two platinum points in contact.

The interrupter lever also carries a fibre block, which extends beyond the periphery of the metal disc, as will be noted at B, and when the block comes in contact with a segment it is depressed, which action separates the platinum points, breaking the primary circuit. The segments causing the separation of the points are stationary members, integral with the circuit breaker housing, the metal disc and its components revolving with the armature shaft.

One end of the primary circuit of the magneto is grounded to the armature core, while the other, or live end, as it may be termed, is connected to a brass plate, through the centre of which passes the screw shown at A, and to the insulated contact piece. The other side of the circuit is obtained from the armature core, the connection being established by the carbon brush, metal disc, interrupter lever and its platinum point. When both points are in contact the primary circuit is closed, but upon their separating a high-tension current is induced in the secondary winding of the armature or in the transformer, or step-up coil, it depending upon the type of magneto.

Time of Break.

The time of the separating of the points is of great importance and the maximum efficiency is obtained when the winding on the armature is cutting the great-

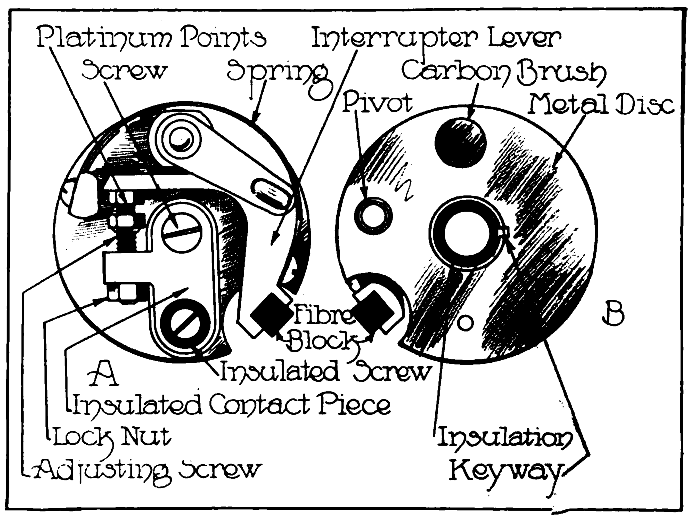

Fig. 57—Interrupter Mechanism of Bosch Magneto: A, Front View Showing Interrupter Lever and Fixed Platinum Point; B, Rear View.

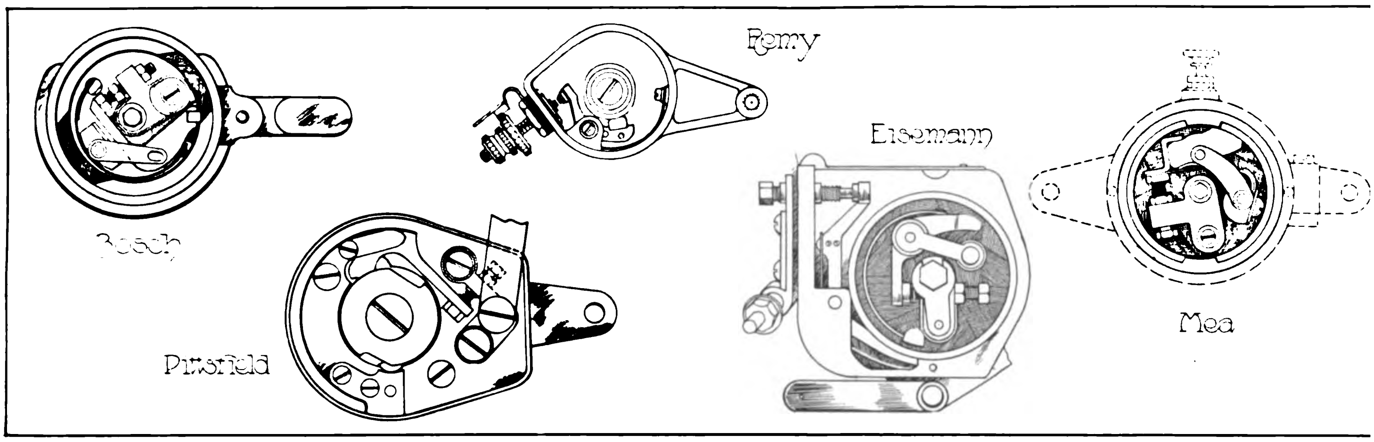

Fig. 58—Conventional Types of Magneto Make and Break Mechanisms, Including Bosch, Remy, Mea, Pittsfield and Eisemann.

est number of lines of force. It is at exactly these two positions that the current must be broken, and it is, therefore, evident that the mechanism causing the make and break must open and close in a fixed relation to the position of the armature.

That the interrupter mechanism does not always revolve with the armature shaft will be noted by the illustrations of conventional types shown at Figs. 58 and 59 respectively, although the principle involved is similar. By referring to the breaker box of the Remy magneto at Fig. 58 it will be seen that the armature shaft carries a two-point cam, which actuates the interrupter lever pivotally mounted in the breaker box proper. With this type the second contact point is an adjustable screw which is well insulated from the metal of the breaker box housing, and it will be seen that the primary current is established and broken twice each revolution of the armature shaft. A feature of the Remy breaker box is the ease with which adjustments may be made and from the outside. The gap or break of the points may be set when the magneto is operating. This is an advantage in that faulty operation at low speeds may be corrected easily. The Pittsfield utilizes a cam arrangement, as does the National, Connecticut, Kingston and Splitdorf.

The breaker box of the Eisemann, shown at Fig. 58, differs from the other types in that a separate circuit breaker is utilized when the source of current supply is batteries. It should be explained that with man so-called dual types of magnetos the batteries are util ized for starting purposes and for operation as wel but in the majority the circuit breaker of the instru ment is employed for interrupting the primary circui when the current is supplied from batteries and th magneto. The distributor, which will be taken up i the next installment, also serves to distribute the higl tension current. The advantage of the Eisemann ir strument is obvious. It permits of operating on th cells or battery even when the magneto circuit breake is defective.

Function of Segments and Cams.

The number of segments or cams utilized in th breaking of the primary circuit of the magneto de pends upon the number of cylinders. If it be a single cylinder engine there is but one break to each revolu tion of the armature shaft and but one segment em ployed, but with multi-cylinder motors, fours an sixes for example, there are two breaks to each revo lution of the armature. It is obvious that the contact are broken and re-established a great many times du ing a minute and that the operating parts must nc only be constructed of high grade material, but fir ished and adjusted with extreme care.

Distribution of Current.

The high-tension current of the magneto is sup plied to the spark plugs and in the proper order b the distributor, contact being made by the arm c

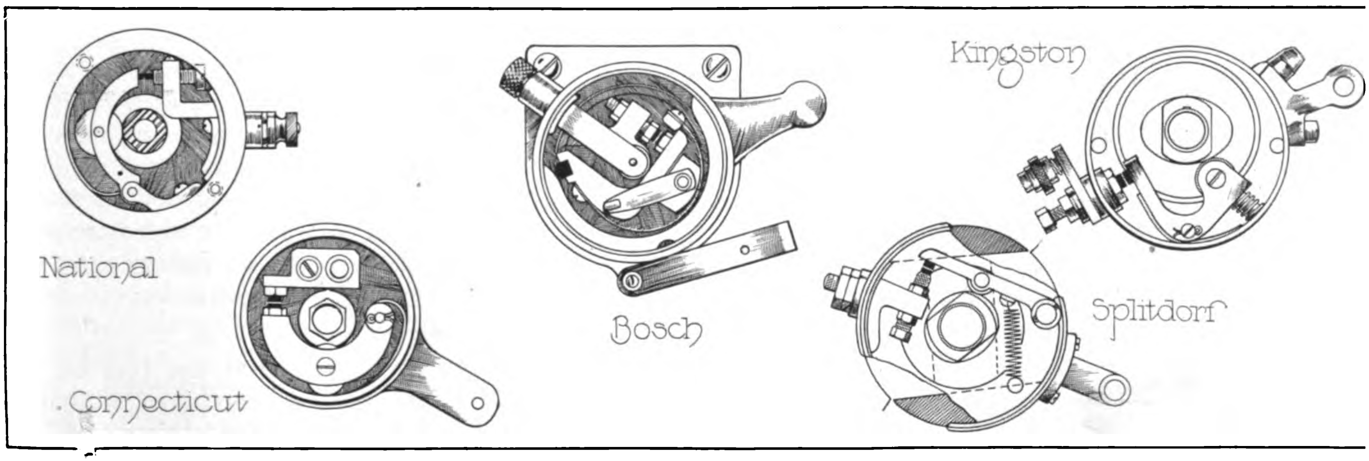

Fig. 59—Other Forms of Primary Circuit Breakers Showing National, Connecticut, Splitdorf and Kingston Employing Cams, and Bosch Single-Cylinder Breaker Box.

brush conveying the current to the segments. The principle is similar to that of the high-tension distributor utilized in connection with the coil and battery system of ignition. The distributor arm of the magneto is actuated by a gear in mesh with a smaller member secured to the armature shaft and rotating in an opposite direction. This arm makes but one complete revolution to two of the armature shaft, but during the movement contacts are made with four segments when a four-cylinder motor is being supplied with current.

To obtain a different number of sparks, as with a six-cylinder motor for example, the speed of the armature shaft is varied. Thus with the four-cylinder engine the armature is rotated at crankshaft speed, while with the six-cylinder motor it is driven at 1.5 times crankshaft speed. As there are but two breaks in the primary circuit each revolution, the armature must revolve three times in two revolutions or 1.5 times in each revolution of the motor to obtain the required total. In each 1.5 revolutions of the armature the distributor arm touches three segments. In other words, the distributor arm makes half a revolution to 1.5 of the armature.

(To Be Continued.)

Ed. Note—The next installment will deal with the construction of the distributor, showing how the high-tension current is supplied to the plugs. The various types of magnetos will also be discussed generally.

KISSELKAR TRUCK A CLIMBER.

Baggage Wagon Did Surprising Work in the West Hudson-Catskill Tour.

During the West Hudson-Catskill reliability tour, May 14-15, a two-ton KisselKar wagon carried the baggage of the tourists, and while it was not required that the machine take part in the competition, it was tested for the hill climb at Haines Falls, N. Y., where the most difficult grade of the route, the Kaaterskill Clove mountain, was ascended.

Carrying 20 persons and the luggage the climb was made in six minutes and two seconds, a work that can be the better appreciated when it is known that three of the leading pleasure cars took more than five minutes. In addition the wagon climbed the Crow's Nest hill, which was regarded as even a harder ascent.

PREMIERS IN TELEPHONE SERVICE.

One Light Motor Vehicle Does Four Times the Work of Single Horse and Wagon.

The Chicago Telephone Company three months ago purchased three Premier light wagons, made by the Premier Motor Manufacturing Company, Indianapolis, Ind., to be used for delivering instruments to new subscribers. The company's carefully kept records show the machines have averaged 115 deliveries a day against a delivery of 30 instruments by horse and wagon. In other words, one motor vehicle does in one day what the horse and wagon accomplished in four.

The delivery cost under the old method was 31 cents; under the new method it is nine cents. This quick installation establishes the subscriber as a dividend payer four times as rapidly as under the antequated method, thus making a still more economic saving.

COSTS LESS THAN SHOEING.

Result of Experience with Chase Trucks in Service with California Laundry Concern.

The Soft Water Laundry Company, Long Beach, Cal., operates one of the five largest laundries in southern California. The company installed a Chase motor truck originally and since then other Chase machines have been added until it now has a fleet of these vehicles in service. They are made by the Chase Motor Truck Company, Syracuse, N. Y.

The first wagon has operated continuously every working day for a period of 21 months. Manager Beck of the company states that he is willing to make affidavit that the entire repair expense covering this period of 21 consecutive months amounts to a total of only $3.65. He adds that during the next few months the concern will supplant its entire equipment of horses. It cost less, he asserts, to keep the first Chase truck in repairs than it would have cost to shoe one of the horses during the same length of time.

EMPLOYEES SHARE IN PROFITS.

Williams Foundry and Machine Company Distributes Liberal Portion Among Its Workmen.

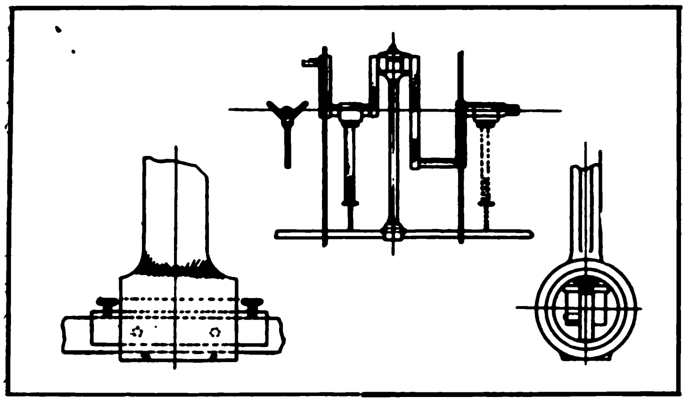
Each of the employees of the Williams Foundry & Machine Company, Akron, O., was recently presented by J. K. Williams, president and founder of the concern, with an envelope containing a substantial sum of money. An accompanying card stated the reason for the gift. The company has had a prosperous year and recognizing the part played by its faithful non-salaried employees dispensed among them $1500.

Five hundred dollars was divided according to the length of service with the company, by which was meant uninterrupted service, except for necessary absence, for more than a year previous to March 29, 1913, and $1000 was apportioned according to the number of hours worked during the year regardless of amount earned. Last year the company distributed $1000 among its employees and that labor troubles are and have always been unknown in its factory may be ascribed, in part at least, to the above action.

After a series of interesting tests, the DuPont de Nemours Powder Company has purchased a Studebaker delivery car, made by the Studebaker Corporation, Detroit, to carry detonators on a route through the Pennsylvania and West Virginia mining districts.

HINTS FOR PROPER MAINTENANCE.

ALTHOUGH one may be careful in fitting and scraping bearings, this does not necessarily mean that the axis of the bearing will be exactly in



Special Straight Edge for Verifying the Alignment of Bearings with Wristpins, Etc.

line with the wristpin. The centre line of the wristpin bushing will frequently be found to be inclined toward the centre line of the crankshaft, owing to the fact that the connecting rod has become slightly bent or out of alignment. It is not always easy to detect the defect before assembling and to facilitate matters the special straight edge shown in an accompanying illustration will be of service.

If it is used in connection with a length gauge, one having a V block at one end and a screw extension at the other extremity, the slightest variation in trueness in the horizontal plane may be noted readily. Similar misalignment in the vertical plane may be discovered by using an ordinary straight edge. It will be noted that provision is made for adjustment in order that worn wristpin bushings or those of larger or smaller dimensions than standard may be accommodated, two set screws being provided for this purpose. Other set screws in the side of the straight edge permit of taking up any slack sideways.

REMEDYING SLIPPING CONES.

Some of the older types of pleasure cars, a large number of which have been converted into delivery vehicles, are fitted with ball bearings which are adjusted by moving the outside cone on the spindle toward the hub. When the cone has been replaced a number of times the spindle becomes worn and the cone does not fit snugly, resulting in its rotating with the wheel. This condition brings about friction and wear of the spindle and adjusting nut. When it is found that the cone is slipping it may be cured by taking a small cold chisel and nicking the spindle so that a drive fit of the cone is secured.

LUBRICATING VALVE STEMS.

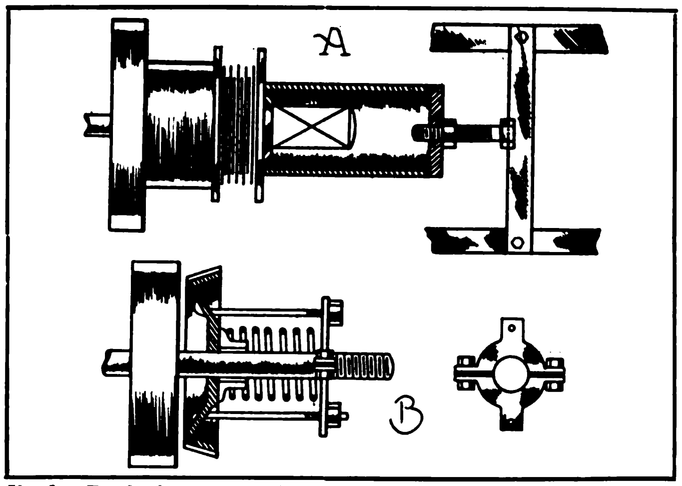
In grinding in the valves of the motor it is essential that they be cleaned before replacement. As the valve stems and their bearings are subject to considerable friction it is advisable that the stems be well lubricated before being replaced in the cylinders. Failure to provide proper lubrication is apt to result in undue wear and in the admission of auxiliary air. Grease or oil does not serve as the heat causes these lubricants to dissipate. The best method is to employ a grease graphite, smearing the stems, or to use a powdered graphite mixed with oil.

JIG FOR CLUTCH SPRINGS.

Unless one be careful in replacing clutch springs the fingers and hands are apt to be injured. A simple and easily constructed jig for replacing multiple disc types is shown at A in an accompanying illustration. It comprises a tube of sufficient inside diameter to slip over the shaft and a plate equal in diameter to that of the tube. The plate is drilled to take a .625-inch bolt, which is fitted with a nut. The head of the bolt is cut as shown so that it will not slip when the nut is screwed up. The jig shown at B differs from the one described in that it is applicable to cone clutches, and as will be noted, the plate member is made in two pieces or halved, so that it may be removed easily.

RESTORING DRY CELLS.

With some dual systems of ignition dry cells are utilized for starting the motor, after which the current from the magneto is switched on. As the cells are used only for starting they are not given the attention they would be were they employed for running purposes. Various methods are given for temporarily restoring dead dry cells or those the amperage of which is too low to permit of starting the motor, among which may be named that of drilling through the sealing compound and moistening the depolarizer with water and vinegar. The following hint is given by a battery concern: Take a piece of hard wood and with a



Jig for Replacing Clutch Springs: A, Type Applicable for Multiple Disc; B, Showing Application to Cone Clutch.

light hammer drive down the material surrounding the carbon post. It is said that amperage is increased considerably by this treatment.

NEW KEROSENE AND BI-FUEL CARBURETORS.

ANNOUNCEMENT was made recently by the Findeisen & Kropf Manufacturing Company, Chicago, of a new combination Rayfield carburetor. It is the invention of Charles Rayfield, who also designed the conventional Rayfield carburetor, and is for service on traction, stationary and marine engines, although it is understood that the inventor is conducting a series of experiments with a similar instrument applicable to automobile motors. The operation of the new device is automatic, and it is held that a perfect mixture is supplied to the cylinders at all speeds and under varying loads when using kerosene, distillate or other heavy grade fuels. Water is automatically fed with the kerosene.

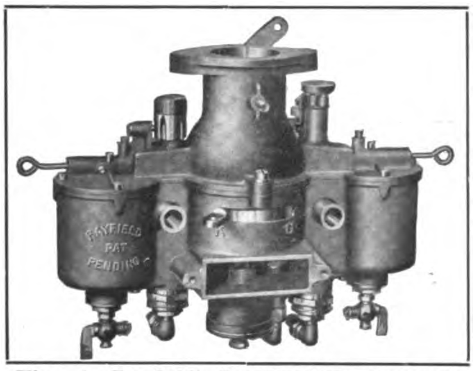


Fig. 1—Rayfield Combination Kerosene and Gasoline Carburetor.

As will be noted by the illustration at Fig. 1, two float chambers are provided. This permits the use of two separate fuels and makes it possible to start on gasoline in the conventional manner and to operate on that fluid if desired. Upon the desired heat being obtained the gasoline is cut out and kerosene employed. This is brought about by the movement of a small lever which controls the supply of both fuels. Two separate adjustments are provided. The required heat for vaporization of the heavy liquid is obtained from the exhaust manifold, a pipe connecting the latter to the air intake of the kerosene member.

NOBLE BI-FUEL CARBURETOR.

Among the more recent carburetors brought out abroad and designed for use with kerosene and heavy fuels is the Noble, an English product, part sectional views of which are presented at Figs. 2 and 3. It will be noted that two distinct float chambers are provided and that from each of these leads a jet, which is shown at B Fig. 3. The tip of each jet passes into a choke tube C, the bottom end of which is provided with means for adjusting amount of air passing the jet. Both choke tubes extend into the chamber D, which has a rotating sleeve valve. The latter makes it possible to cut off either the gasoline or kerosene, or to utilize both these fuels simultaneously.

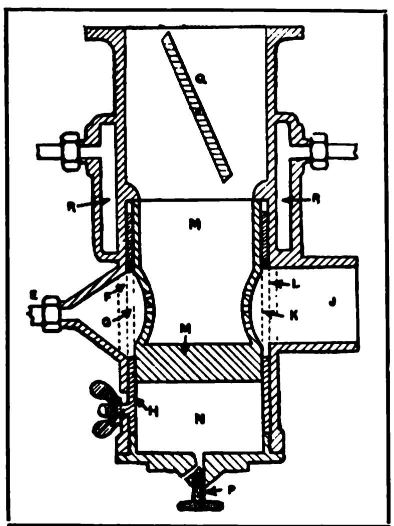

Fig. 2—Mixing Chamber of Noble Bi-Fuel Carburetor.

From the chamber D the rich mixture is led into a vaporizing tube E, which passes into and along inside the exhaust branch, finding exit through a packing gland at the front end of the motor, whence it is led to a mixing chamber illustrated at Fig. 2.

The gas from the vaporizing tube E passes through a slot F in the wall of the mixing chamber and a corresponding slot G in the sleeve H. The latter is employed for adjusting the proportions of gas and air to provide a correct mixture. Additional air enters the mixing chamber by the way of the pipe J from an open ended warming jacket around the exhaust pipe. The slots K and L correspond more or less according to the position of the sleeve H, which also has a rotary movement, so that these slots also work in conjunction with the slots F and G. The slots on both sides of the sleeve H are uncovered internally by a piston M, which rises or falls according to the negative pressure in the mixing chamber, this pressure being governed by the position of the throttle and speed of the engine.

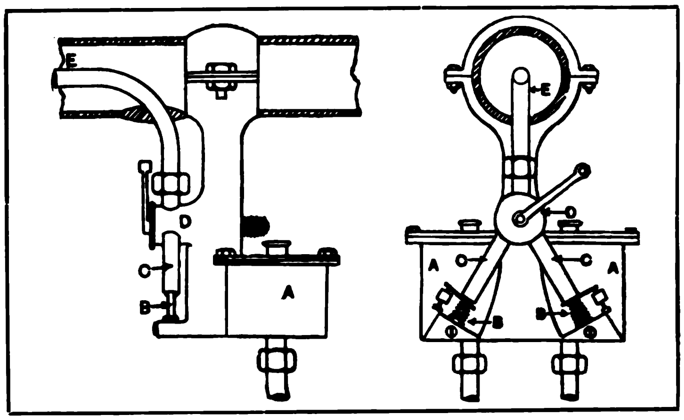

Fig. 3—Part Sectional Views of Float Chamber Portions of Noble Carburetor Utilizing Gasoline and Kerosene Independently or Together.

The piston M has holes communicating with the slots in the walls of the chamber, these apertures allowing the air and gas to pass through to the motor. Below the piston is a dash pot space N having an adjustable screw P. A hot water jacket R is also embodied in the mixing chamber casting.

The slow speed is adjusted by moving the sleeve H vertically, and when the desired position is obtained the sleeve is locked by means of a wing nut. The carburetor includes the conventional butterfly throttle valve, this being shown at Q and being located above the piston member.

The engine is started on gasoline and as soon as the exhaust pipe attains a certain temperature the two-way valve is utilized, bringing kerosene into service. In either case a rich mixture is provided, and the fuel is vaporized in its passage along the vaporizing pipe E. The level of both fuels is controlled by means of floats and needles in the conventional manner.

CORRESPONDENCE WITH THE READER.

Timing Valves of Ford.

(35)—What method is pursued in timing the valves of a model T Ford car? We use two of these in our business and the motor of one is not developing the power it should owing to wear of the valve stems. As the stems are not adjustable it would appear that either new ones would have to be used or the old ones drawn out. Is there any suggestion you can make? READER.

Schenectady, N. Y., June 15.

There are two methods employed in timing valves, one by the flywheel and the other by the piston travel. The latter is used with the motor mentioned and in an accompanying illustration is presented a timing diagram, the opening and closing points for the exhaust and intake valves being shown.

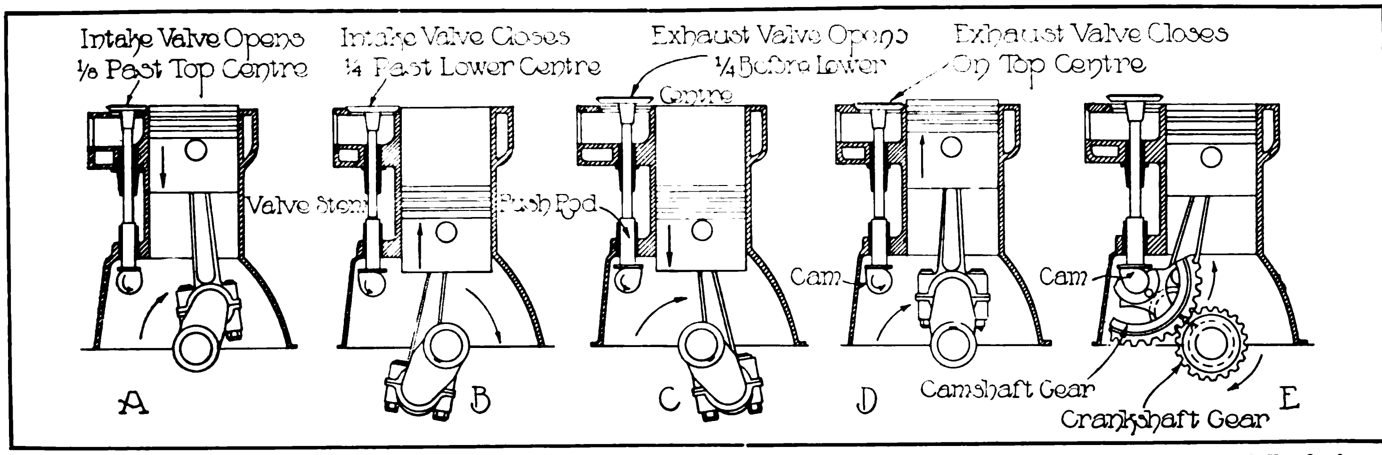
As will be noted by the diagram at A, the intake valve opens one-eighth past top dead centre on the completion of the exhaust stroke of that cylinder, the No. 1, for example. It should be borne in mind that there are four strokes to each cylinder, these being intake, compression, firing and exhaust, in that order. Consequently, in timing the intake valve of the first cylinder it should be open when the piston has completed one-eighth of the downward stroke or piston travel. As the stroke of the piston is four inches this is a simple case of mathematics.

The intake closes one-quarter past lower centre, or in other words, the piston has completed the intake stroke and has begun the compression stroke as shown at B. With the piston in this position the valve should be on its seat with a suitable space between the valve stem and pushrod or tappet as illustrated in the drawing. The timing of the exhaust valve is accomplished in a similar manner. The exhaust opens one-quarter before the piston reaches lower dead centre as shown at C and closes on top dead centre as illustrated at D. The valves of each cylinder should be timed separately.

The clearance between the valve stem and the pushrod should never be greater than .03125 inch nor less than .015625 inch. If the space is too small the valve is likely to remain partially open, causing faulty operation of the motor. It should be remembered that there is more or less expansion of the metal when hot and this should be taken into consideration in making fine adjustments, and when lengthening the stems or fitting new parts.

The lengthening of the valve stem involves considerable care and it is an easy matter to bend the stems. The better method is to utilize the Aplco valve stem adjusters, which are designed especially for this work. They are manufactured by the Providence Auto Parts Company, Providence, R. I., and are attached easily, being slipped over the stem.

The sketch presented at E shows the method of replacing the camshaft in the event of injury to this member or an overhaul of the motor.



Illustrating Timing of Valves of Model T Ford by Position of the Piston and Its Travel, Also Showing Method of Replacing Camshaft and Meshing the Gears.

Floating the Battery on Line.

(36)—In what respect does a lighting or ignition system with the battery floated on the line vary from others? What is the proper gap for spark plugs, and is there any difference between the space when used on the battery and the magneto? IGNITION.

Hoboken, N. J., June 11.

In a lighting or ignition system with the battery floated on the line, the generator or dynamo maintains the cells in a charged condition and all current utilized is drawn from the battery. A wiring plan showing the system is shown elsewhere in this issue.

The approximate proper gap for spark plugs is .03125 and .015625 inch, the latter being utilized where the source of current is a magneto. Too large a gap with magneto plugs is productive of missing at low speeds, etc.

Direction of Distributor Arm.

(37)—If the shaft of a magneto revolves to the right, in what direction does the distributor arm move? In replacing the plug wires, which would be the No. 1 cylinder? MAGNETO.

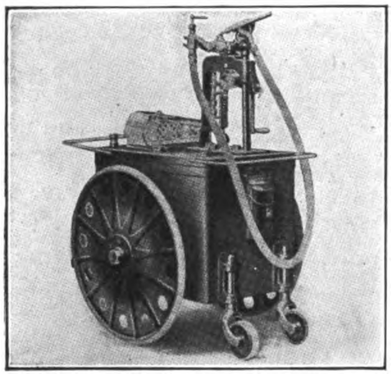
Toledo, O., June 8.

If the armature shaft revolves to the right or clockwise the distributor member rotates in an opposite direction as it is actuated by a gear meshing with another gear on the armature shaft.

In replacing the secondary wires the first cylinder to fire should be connected with extreme right terminal on the distributor housing. The proper connection may be determined by displacing distributor cover and noting position of distributor arm or brush.

GARAGE AND SERVICE STATION EQUIPMENT.

PORTABLE fuel tanks possess advantages in that considerable time is saved in replenishing the supply of gasoline in cars, to say nothing of the convenience. The American Oil Pump & Tank Company, Dayton, O., is marketing the American wheel tank shown in an accompanying illustration and designed to be moved easily about the garage.



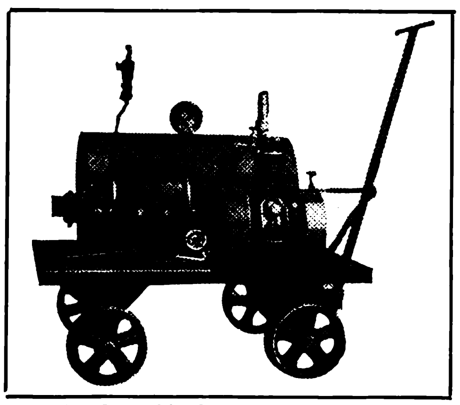
American Wheel Tank.

The tank proper has a capacity of 50 gallons and is constructed of .1875-inch metal, being seamless and reinforced internally. The handles and brackets which support the small wheels are welded to the body of the tank. The latter is carried in a steel basket frame having heavy uprights of steel to which are secured the spindles for the large pressed steel wheels. The steel frame passes underneath the tank, supporting it and eliminating strains. The large wheels rotate in ball bearings and are shod with Goodyear 1.25-inch solid tires. The small wheels are also rubber tired.

The tank is equipped with a wheel brake, contents indicator, properly screened filler pipe fitted with brass cap, and automatic gas and air vents. When specified the equipment also includes a triplicate autographic register and charge slip box, as shown in the accompanying illustration. The pump is a continuous flow member, equipped with a recording gallon meter, gasoline filter, two-way discharge, discharge register and spring lock. It is adjusted to measure a pint, quart, half-gallon and gallon, and it discharges on both the up and down-stroke of the piston. Four and one-quarter turns of the crank discharge a gallon and leave the pump ready for the next operation.

GARDNER AIR COMPRESSOR.

Compressed air in the garage may be utilized for a number of useful purposes. The Gardner Governor Company, 30 Williamson street, Quincy, Ill., is manufacturing air compressor systems both for the small garage and service station, including stationary and portable outfits, and operated either by the power of the garage or by electricity.



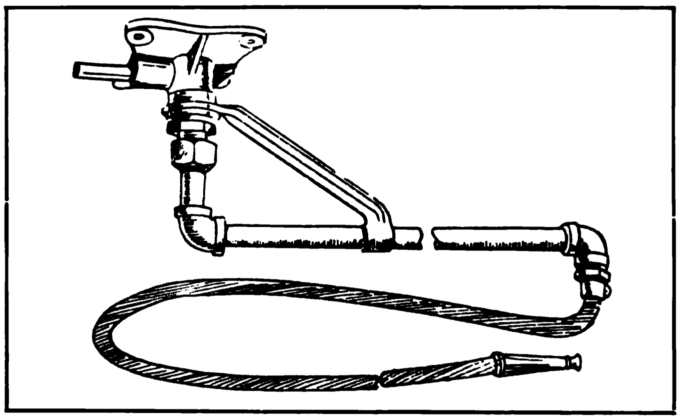
Gardner Air-Cooled Compressor.

The equipment shown in an accompanying illustration is an electrical unit and the design is provided with rollers so that it may be moved as desired, a construction making for convenience. It comprises a Gardner air-cooled compressor connected by gears with an electric motor, an air tank 14 by 26 inches, safety valve, pressure gauge and drain cock. Ten feet of air line with tire connection, 20 feet of lamp cord with socket and a tire pressure gauge are also included.

The air tank is not an absolute necessity with this unit, but it is frequently a source of convenience, especially where the outfit is moved beyond the zone of a lamp socket. In such cases the tank may be filled in the garage and it is stated that there is sufficient reserve capacity to inflate four large tires without refilling.

The Gardner air-cooled compressor is made of high grade material, is semi-enclosed, with trunk piston fitted with metallic packing rings. The crankcase and cylinder are one casting, and steel ball valves are utilized in the head.

The electric motor is a one horsepower, direct or alternating current, two or three-phase, 110 or 220-volt unit.



Walworth Swivelling Type Auto Washer, Designed for Attachment to the Ceiling.

WALWORTH WASHER.

The Walworth auto and carriage washer is the product of the Walworth Manufacturing Company, Boston, and the equipment shown in the accompanying illustration is of the swivelling type and is moderately priced. It is secured to the ceiling by lag screws, and the arm swivels horizontally in a complete circle, eight feet eight inches in diameter. The working parts are of brass, with other components of cast and wrought iron, heavily galvanized.

The washer not only enables the operator to reach easily any part of the machine, but the hose is kept off the floor, adding to its life. The complete equipment includes in addition to the washer and lag screws 15 feet of .75-inch three-ply hose with couplings, and a Boston spray nozzle.

BOSTON'S DELIVERY PROBLEM.

(Continued from Page 509.)

form of package delivery. In the shipping rooms the packages are collected, those in the store delivery room in grating compartments with a locked door. Beneath each compartment is placed a carrier, and this is locked as well. Unlocking the door releases the carrier and it may be drawn out and the packages dropped into it in a very brief time. In the other rooms the packages are placed in compartments and are removed to carriers from time to time. The provision for keeping the records is very complete and the records are exceedingly simplified. The possibilities with this equipment are splendid from an economic point of view, and while the store handles an average of 16,000 packages each day no less than 66,000 have been handled in a day, though, of course, the number of workers was materially increased. From every point of view labor is saved and the safety of the packages insured.

The carriers, when filled, are taken to the elevators from the shipping room to the street. There are four elevators on Avon street and four on Bedford street, but some of these are used for freight, and the greater part of the wagons are loaded in Avon street. The store has its own delivery equipment of three three-ton Packard trucks, one 1000-pound General Vehicle and four 1000-pound Commercial electric delivery wagons, nine 3000-pound Autocar delivery wagons and 55 wagons. The company's stable contains 135 horses and is in Harrison avenue. The electric wagons are garaged at the stable, the Autocars are kept at the Autocar service station, and the Packard trucks are kept at another garage. One of the electric machines, a Commercial, and the Packard trucks have been used three years, the other electrics about two years and the Autocars since last October. The drivers are paid $16 a week and the helpers an average of $9.

Four deliveries are made in the "city," at 10:30, 1:30, 3:30 and 5, and for this work horse wagons are used. The store equipment makes delivery in Newton once a day by horse wagon, in Roxbury, South Boston and Charlestown twice a day by horse wagon, in Chestnut Hill and Newton Center, Brighton, Medford and Allston twice daily by electric wagon, in Dorchester by electric and horse wagons, in Somerville, Cambridge and Brookline by gasoline and horse wagons, and in Newton Highlands, West Newton, Malden, Jamaica Plain, Forest Hills, West Roxbury and Roslindale, twice each day by gasoline wagon. Delivery is made once each day by expresses in Winthrop, Lexington, Everett, Stoneham, Wakefield, Atlantic, Arlington, Auburndale, Marblehead, Belmont, Saugus, Westwood, Blue Hill, Canton, Reading, Newtonville, Newton Upper Falls and Newton Lower Falls, and twice daily in Wellesley, Melrose, Dedham, Waltham, East Boston, Hyde Park, Salem, Woburn, Braintree, Quincy, Winchester, Lynn, Chelsea, Watertown and Revere. In addition there are the services of all classes of express companies and the parcel post.

All of the loading of the store, however, is by the elevators and carriers, and the packages are sorted and arranged in the wagons while they are standing at the sidewalks. Most of the loading is done in Avon street. The sidewalks are narrow and the street will permit one vehicle to pass with a vehicle standing at either sidewalk. This street is one way, all vehicles passing from Washington street to Harrison avenue extension, and it is used by thousands of shoppers who have their own conveyances. The traffic ordinance permits a wagon to stand five minutes unattended and 20 minutes when attended.

The wagons are lined along Avon street headed toward Harrison avenue extension, and from the main entrance to the annex to that street. In Bedford street they are similarly lined from Harrison avenue extension to the entrance. It is necessary to take the packages from the carriers and sort them for delivery, and aside from the awnings there is no shelter. The sidewalks are narrow and the streets are greatly used during the day. The system of loading here, however, is such that all of the wagons are not in the streets at any one time save when loading for the city deliveries. It would be practical, however, to load some of the wagons in Harrison avenue extension by making entrances and installing elevators at that end of the building.

At the White Store.

The store of R. H. White & Co. is located in the square surrounded by Bedford and Washington streets, Harrison avenue extension and Norfolk place. The shipping room of this concern is located in the basement at the corner of Harrison avenue extension and Norfolk place and the packages are taken to it by elevator and from the first floor by a chute. The company is now preparing to make material improvement in this department and this will include the most improved facilities that can be installed in the space that is available. The company handles approximately 1,000,000 packages annually, but this does not include the delivery from the contract department, which will undertake to furnish a room, a flat, a house or a hotel of any proportions, furnishing everything required for occupancy. The house does not sell provisions or groceries.

The goods are sent out of the shipping room by a small elevator and an entrance of moderate width, and the receiving is by a somewhat larger elevator. As is shown by the photographs the delivery elevator is at the corner of the building in Norfolk place, an alley that has a roadway of about seven feet with a 30-inch walk at either side. Wagons can be driven into this street and either backed out or driven through, but the walks are too narrow to load from. Harrison avenue extension, however, is wide and the wagons can be placed at either side of the street, but only loaded from one. Receiving freight sometimes interferes with loading, but the purpose of the shipper is to have the wagons and machines so relayed that not more than

six are at the store at any one time. The sidewalk is not wide, and there is a good deal of traffic in both the roadway and walks. The pedestrians, of course, interfere with the work to some extent, and there is no shelter in the event of storm.

The company uses two two-ton Garford trucks, a 3000-pound White wagon, two three-ton Mack trucks, two 3000-pound Autocars and two two-horse wagons, while in the regular store delivery are used nine 3000-pound Autocars, one 1000-pound General Vehicle wagon and 14 single-horse wagons. The store wagons make delivery in the "city" and in Allston, Ashmont, Auburndale, Beaver Brook, Bemis, Brighton, Brookline, Cambridge, Cambridgeport, Charlestown, Chelsea, Chestnut Hill, Cottage Farm, Dorchester, Dorchester Lower Mills, East Boston, East Cambridge, East Somerville, Faneuil, Forest Hills, Harrison square, Jamaica Plain, Longwood, Mattapan, Melrose, Neponset, Newton, Newton Center, Newton Highlands, Newtonville, Nonantum, North Cambridge, Oak square, Point Shirley, Revere, Riverside, Riverview, Roberts, Roxbury, Savin Hill, Waltham, Watertown, West Cambridge, West Newton and Winthrop. Deliveries are made by express services in 77 other different sections that are named on the shipping card, and these are regarded as the regular suburban delivery. Besides this there are the regular general and New England express companies and the parcel post.

Shepard, Norwell and Siegel.

The Shepard, Norwell Company's store is located between Winter and Temple streets and there is but one entrance to the store building from Winter place, this being a "blind" court that extends about halfway through the block to Temple street, there being a roadway about seven feet width and 30-inch sidewalks at either side. There is a bulkhead and an entrance for an elevator constructed for carrying freight, and at this entrance all the freight is received and all the shipments sent out. It is necessary to back any vehicle driven into the court out to Winter street, and Winter street is narrow and at all times in the day is congested. The delivery from this store is made by the Boston Parcel Delivery Company in the city, by a single General Vehicle 1000-pound electric wagon used in the Back Bay, and by the numerous local expresses. In the city the deliveries are made four times daily and elsewhere from one to four times a day. Of course the general and New England express companies and the parcel post service are used for places not reached regularly by the store service.

The Henry Siegel Company does not own motor vehicles, but it does its freight haulage and its delivery by about 125 horses. The store equipment is used in the city and the suburbs and the express services are employed as by the other stores, the radius of direct store delivery being within 10 miles, but not all localities are reached. The store rents trucks as they are needed for furniture delivery and it also provides for special delivery with rented automobiles. The shipping room of this company is in the basement of the building, the packages being collected on each floor and sent down through spiral chutes. They are sent to the different parts of the shipping room by belt conveyors and thence distributed to the different sections and placed in bins or carriers and the records made. Later on they are taken by elevators to the sidewalk. The store supplies and a considerable part of the stock is received at the elevator near the corner of Harrison avenue extension in Essex street, and the very large and bulky goods, especially furniture, are received and shipped at the large elevator in Haywood place. The parcels for the regular delivery wagons are taken in carriers to the sidewalk in Harrison avenue extension and there sorted and placed in the wagons. The sidewalks are narrow and the traffic is at times very heavy in them. It is not possible to load all the wagons at any one time, a dozen being the largest number that can be placed at the sidewalk, and frequently others are kept waiting at the other side of the street until there is loading space. Neither the Essex street nor the Hayward place sidewalks are used for loading. Here the same traffic regulations obtain. The greater part of the Harrison avenue sidewalk is partly covered by a canopy, but there is no protection for the vehicles. This store is advantageously located for a loading space within the building, for a drive could be made through the structure from Essex street to Hayward place.

The Electric Express.

Besides the express services that have been specified a factor that is of growing importance is the electric express, which is a combination of the Bay State Street Railway Company, the Boston & Worcester Street Railway Company and the Brockton & Plymouth Street Railway Company. This does not extend north of Boston, but it reaches Plymouth, Fall River and New Bedford, Mass., on the south, Newport, Providence, Narragansett Pier in Rhode Island, and Worcester on the west. A glance at the map will show the area covered by this service and its connecting lines. The Boston terminal is Copps Hill wharf, where all freight is received, and at 536 Harrison avenue is the express office. The company handles freight to all its stations, and express to all stations save those on the lines between New Bedford and Fall River, and Fall River and Providence. The freight service means transportation of any commodity from one terminal to another. The express is divided into two classes of service, the one where collection or delivery is made at one end, and the other where collection and delivery are both made. The former is known as the "B" and the latter as the "A" class. The company has an equipment of 20 wagons busy in Boston making collection and delivery, and it has its own vehicles or contract with owners of wagons for the handling of the packages in many of the towns and cities. The accompanying rate table shows the towns and cities where the "A" service can be given. The shipments are made eight times daily to points south of Boston and five times to points west of that city, so

there is certainty of quick deliveries anywhere the company has representation. In all 180 different places are now reached, and of these 118 are where freight only is handled.

Lack of space prevents a more detailed statement of the facilities of the stores and the endeavor made to expedite the work, but there is, for instance, between the Jordan, Marsh store and the furniture warehouse in South Boston a telautograph, by which, when an order is written by a clerk in the salesroom for a sale made by sample, the order is copied in the warehouse office and it is known to be correct and the record is complete. This is quicker than telephoning and it is a decided saving in time.

It would be impossible to estimate the number of vehicles used in the service of the stores and the express companies and it is impractical without this exact information and a precise knowledge of the work accomplished by each company to know what might be done in the way of motorizing these equipments. It is evident, however, that motorization would result in a decided street economy, that it would save the time of the men to a very large degree, but it is obvious, as the loading facilities are generally inadequate, that a complete change would be necessary to realize the greatest economies. There could be a decided saving with horse equipment, and a great deal more with motor wagons and trucks, but horse methods must be abandoned to obtain anything like what appears practical and possible.

To motorize the express companies would require different types of machines, for trucks would be necessary for direct haulage and lighter vehicles for distribution. The volume of business is increasing constantly and the requirements of the people are more exacting. The limitations of animals have been reached, and the solution of the situation must be in the utilization of automobile vehicles.

Harry Tipper, advertising manager of the Texas Company, former president of the Technical Publicity Association and a member of the educational committees of the Association of National Advertising Managers, Associated Ad-Clubs and Advertising Men's League of New York, has been engaged as a lecturer in the division of advertising of the school of commerce, accounts and finance of New York University, and will instruct in advertising science during the evening sessions of the college year of 1913-1914. Mr. Tipper's courses will include the psychology of advertising and selling, advertising campaigns and the essentials of advertising.

BUYS TEN WILLET WAGONS.

J. N. Adam & Co. Installs a Fleet for Its Buffalo, N. Y., Department Store.

J. N. Adam & Co., Buffalo, N. Y., which conducts one of the largest department stores in that city, has purchased and installed a fleet of 10 delivery wagons of 1500 pounds capacity, built by the Willet Engine & Truck Company of Buffalo. The firm is one of the chain of stores controlled by H. B. Claflin & Co., of New York City, there being 38 of these emporiums throughout the country, 35 of them being outside of the metropolis. The machines replace horse and contract delivery and it is expected that the improvement in the service will be materially reflected in the business transacted.

The Willet Engine & Truck Company first began to build a two-ton wagon, which is equipped with the four-cylinder two-cycle Willet engine, this having patented rotary valves and a number of exclusive features.

One of the Fleet of 10 1500-Pound Willet Delivery Wagons Purchased by J. N. Adam & Co., One of Buffalo's Largest Department Stores.

It is claimed for this engine that it is especially economical and enduring, has unusual power, and that it has been proven by eight years' experience.

As will be noted from the illustration the chassis is equipped with a half-panel body that is fitted with wire gratings at the sides and rear, curtains affording the necessary protection in the event of storm. The driver's seat is covered by a hood or bonnet that extends beyond the dash and in the seat side panels are ornamental oval plate glass windows. The chassis has a long running board and graceful fenders, these having a decidedly attractive effect, and the wheels are fitted with pneumatic tires. Drive is at left side and control levers are in centre at driver's right.

The annual convention of the Electric Vehicle Association of America will be held at Chicago, Ill., Oct. 26-27, and plans for this event are now making by a committee headed by Homer E. Neisz of the Cosmopolitan Electric Company of Chicago.

SECRETARY DRAPER RESIGNS.

Retires from Electric Motor Car Club of Boston to Engage in Business.

At the last meeting of the Electric Motor Car Club of Boston, held at the Hotel Thorndike the evening of June 19, the resignation of Business Secretary O. G. Draper was accepted to take effect as soon as his successor could be elected and sufficiently informed to take up the work of the club. Mr. Draper intended to devote his entire time to his duties as head of the O. G. Draper Advertising Agency, which has been established at 755 Boylston street, Boston. Mr. Draper was elected business secretary about the first of the present year and was very successful in the work, he also occupying a similar position with the New England section of the Electric Vehicle Association, from which he will retire.

At this meeting it was stated that the importance of the electric motor vehicle was such as to justify the presentation of a paper relative to its utility, at the annual convention of the New England section of the National Electric Light Association, to be held in September, and this paper should deal with the methods of promoting the use of the machines from every point of view. A committee of three was appointed to prepare the paper, and this committee was authorized to present whatever facts were believed necessary or desirable.

Two General Vehicle Electric Trucks, Fitted for Hauling Ice and Bottled Distilled Water, in the Service of the Consumers' Ice Company, Sioux City, Ia.

The club is making a campaign to increase its membership and a number of applications were received and the petitioners elected to the club. A series of interesting statistics relative to registration of electric vehicles in New England and in Massachusetts, both pleasure cars and freight wagons, was read by Secretary Draper, showing the number gained in the year ending June 14, and a summary of the charging stations in New England was presented. It was stated that this list of 208 stations would be amplified from time to time.

ELECTRIC TRUCKS AT PIERS.

Results with Fall River Line Impels New York Merchants to Advocate Their Use.

The traffic bureau of the Merchants' Association of New York City is advocating the use of electric industrial trucks on the steamboat and steamship piers of New York after careful observation of an installation of machines at the shipping terminals of the Fall River and Providence lines. Few persons, unless they have studied the conditions existing at those piers, understand the great loss through congestion and delay of vehicles, which is resultant from the methods of handling the freight. To illustrate, every incoming vessel brings freight that must be unloaded, and in the case of the lines giving daily service this means for several hours after arrival the docks are piled with packages and bales that must be removed. Then comes the flood of shipments that must be received at the piers and rushed on to the vessels and stowed.

At the piers of the lines stated a new receiving platform has been constructed, across which freight intended for shipment is quickly loaded upon electric industrial trucks, which are run upon the vessels, this eliminating much of the handling and increasing the efficiency of the dock facilities. This also minimizes the time for the trucks delivering the freights, for they are not required to wait in line for opportunity to enter upon the piers. The elimination of the hand trucks has the insurance of safer handling, and reduces breakage resultant from the overloading of hand trucks as the sailing time approaches and the men work with extreme haste. This also lessens the number of claims for damages.

So decided has been the improvement that the traffic bureau of the Merchants' Association, after inspecting the equipment and facilities, advocates the use of similar machines and methods on other piers with the hope of bringing about similar improvement.

The proposition of the Motor and Accessory Manufacturers to conduct a separate show at Madison Square Garden during the progress of the next New York automobile exhibition has not been approved to an extent that will seemingly justify its organization, and it is probable that the members of the association will make exhibits in connection with the car display. The option on Madison Square Garden will, however, be continued that there shall be no exhibition at that building that shall in any way compete with the automobile show.

ALL-MOTOR STORE DELIVERY SERVICE.

Arnold, Constable & Co., One of the Famous Dry Goods Houses of New York City, Has Used Electric Vehicles for 11 Years and Is Now Without Horses.

By F. Nelson Carle.

THE well known wholesale and retail dry goods house of Arnold, Constable & Co., was founded in 1827. The store is situated on 19th street and Broadway, New York City, and extends through to Fifth avenue. It is divided into practically two equal parts, the Broadway end being devoted to retail service and the rear half to the wholesale division of the business.

The firm has been without horses for three months. In fact, few horses sold at that time had been retained for the past two years, largely out of sentiment. The all-motor delivery equipment now consists of one 3.5-ton, two two-ton, two 2000-pound and seven 1000-pound General Vehicle electric wagons and a number of gasoline machines.

Arnold, Constable & Co., was among the pioneer users of electric wagons in the dry goods field. Significance is attached to the fact that the wagons bought in 1902 were numbered by the manufacturer 89, 90, 91 and 92 respectively. Other electrics of the same make were added in 1903 and 1906, and early in 1912, two 1000-pound wagons and one 3.5-ton truck were purchased. The gasoline machines have been in service about two years.

The Store of Arnold, Constable & Co., Looking from Fifth Avenue Toward Broadway—This End of the Store Is the Wholesale Department and the Other End Houses the Retail Division.

The directing head of the motor vehicle equipment is George H. Wilson, supervising engineer for the company. Mr. Wilson has been with this one firm 25 years and is one of the best informed men on automobile delivery in the world. It was largely through his patience and hard work that the machines bought by the company in 1902 and 1903 were kept in working order, or, for that matter, retained in service. The manufacturer built a good electric wagon and the battery people a relatively good battery, but it remained for Mr. Wilson to reduce co-operative theory to practise and to evolve a satisfactory method of garaging, charging and operating the wagons on regular routes.

Arnold, Constable & Co., maintains a splendid fireproof garage in Seventh avenue, at 16th street. The electric machines are cared for by a foreman, two battery men, a washer and two watchmen, the latter on night and day shifts. The garage was originally the firm's stable and housed the horses of the company. The empty stalls, old harness and one or two service-scarred, but aristocratic wagons backed against one wall, bear silent testimony to the passing of the horse in at least one phase of city delivery.

The two two-ton and one 3.5-ton trucks naturally serve the wholesale department and transfer goods principally in cases all over the downtown section and part of Brooklyn. The lighter wagons have more varied routes, one being assigned to Jersey, others to Harlem, Brooklyn and the Battery. Four Manhattan

The Twelve General Vehicle Electric Wagons and Trucks Outside of the Garage of Arnold, Constable & Co., Seventh Avenue and 16th Street, New York City.

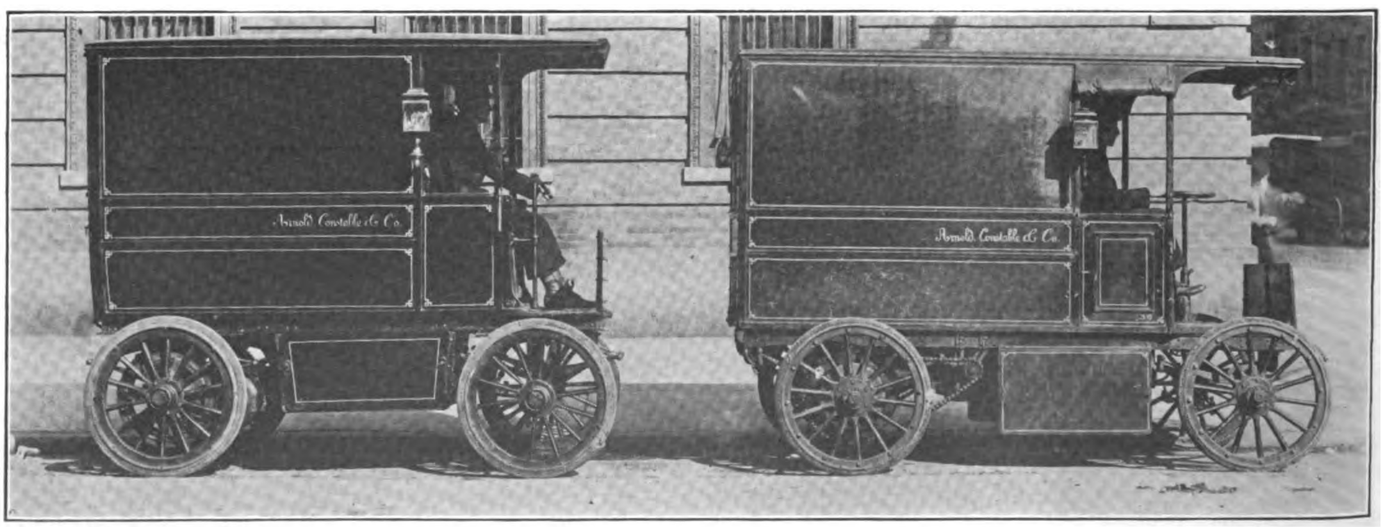
routes are known respectively as High East and Low East, High West and Low West. On all the routes three round trips a day are made and the 1000-pound wagons purchased in 1912 often negotiate up to 50 miles without boosting.

Since the leading dry goods houses of practically all cities regard it as bad policy to give out operating information which they regard as confidential, it is obviously difficult to obtain permission to publish not only specific economies effected by the use of automobile delivery, but even the details of routing the wagons, not to mention the upkeep cost of batteries, tires and similar items. The same applies in general to the wages paid the drivers. It is only by impressing upon the minds of the executives of leading firms the keen interest which other concerns in their line have in the success of pioneer users of motor delivery that even general information of helpful nature to others can be secured.

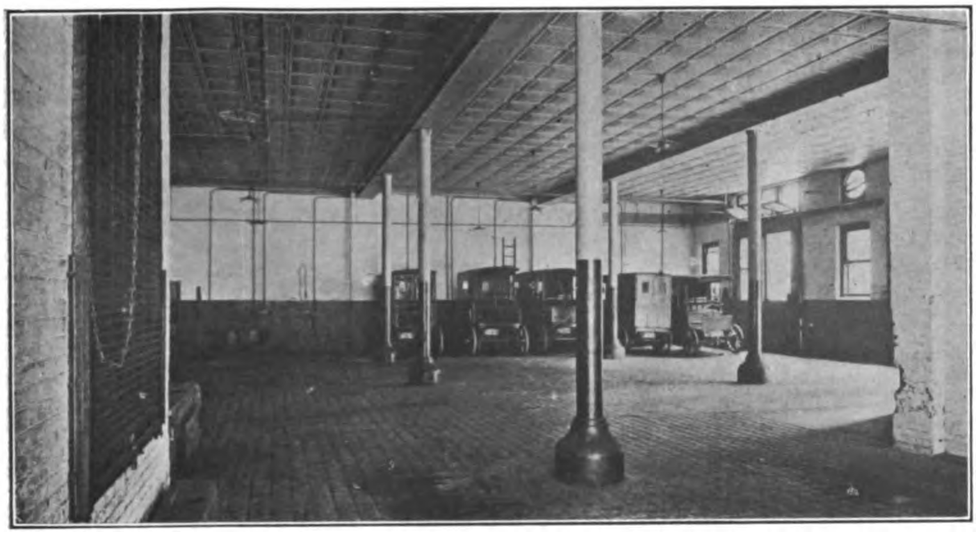
The older users seem to overlook the fact that if the leading department store in perhaps Denver or Omaha had one-tenth the operating knowledge of some of the older users, they could safely install a nucleus of motor wagons and then expand this progressively until they, too, were "horseless." It is true that manufacturers with a large distribution can give the beginner very helpful co-operation, but the new store looks toward the older leading store for advice just the same. The fact that the pioneer user indorses in general the adoption of motor delivery does not seem to be sufficient, and when one looks beneath the surface the reason is obvious. Each merchant imagines (and in some cases with reason) that his delivery problems are peculiar to himself or his city and that he cannot adopt more than a few features of successful installations in other cities. In, say, two years more, the various dry goods associations are certain to take up this general situation and much helpful information will be forthcoming in the discussions. It must be said, in justice to Arnold, Constable & Co., that it has at no time intentionally withheld the benefit of its long motor delivery experience from its brothers in the dry goods trade.

Old Wagons Too Good to Scrap.

"Yes, I suppose we will have to get rid of them some day," said Mr. Wilson, "but wagons 25, 26, 29 and 21 (put in service 11 years ago) seem relatively as good as ever. I have been told that we are behind the times and all that, but even if the wagons have paid for themselves long ago, there is no need of



Old and New Electrics in the Equipment of Arnold, Constable & Co.: That at the Left, a Pedestal Type, Built in 1902, and That at the Right Built in 1912.



Interior of the Garage of Arnold, Constable & Co., Showing About Half the Floor Space and Several of the Electric Machines on Charge.

throwing away equipment that is at the present time giving very satisfactory results. You must remember that it took us a long time to organize this service on a satisfactory basis—in fact, in the early days, we thought several times of going back to horses. We kept putting this off, however, thinking that we would sooner or later get the right combination, and sure enough we did. The problem looks very simple to us now, but you must remember we had no precedent to follow and had to work the whole thing out for ourselves. I think we really were pioneers in getting a satisfactory service, for the other stores expressed their surprise at our doing so well and the battery people couldn't then understand why we didn't buy new batteries every eight or 10 months, or even less, as some others had to do. Things were all pretty much mixed up at that time, but after we got hold of the principle of doing the thing right the rest was comparatively easy."

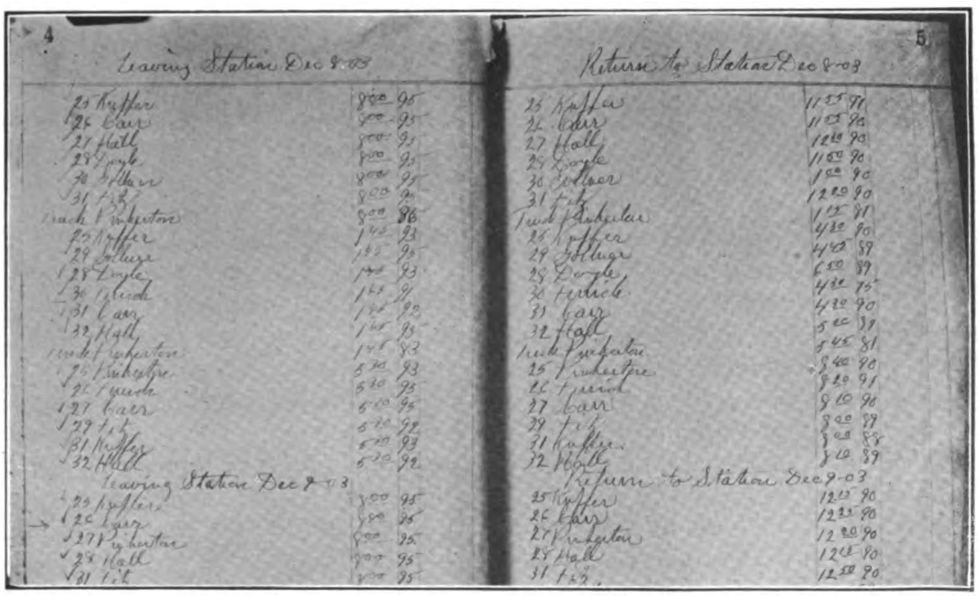
Mr. Wilson cites many amusing incidents of battery troubles, charging mistakes and originality on the part of drivers. Because of his pleasing personality and from his success as a pioneer operator, Mr. Wilson was naturally consulted by a great many others on electric wagon matters of common interest. At that time the charging panels available had no red light to indicate when the batteries were receiving the current. There was one garage where the machines were sometimes not properly plugged in, and occasionally after long charging the wagons would leave the garage, run about an hour and then become stalled. In another case, where he was called in to do first aid work, Mr. Wilson found that the garage man had cut four cells to see what the trouble was and had put the plates back with all the negatives in two cells and all the positives in the other two. He thought that all the plates which were alike naturally went together.

Secret of Operating Efficiency.

The question might well be asked: To what can we attribute the practically uninterrupted success of this pioneer user of motor delivery?

In the first place, the machines themselves were studied through the eyes of an engineer. Their strong points and their weak points were checked up as were their comparative performances under different conditions. Careful records of the four machines purchased in 1902 were put down on paper where they could be referred to readily, and right here is a point which is frequently overlooked by those who are buying their first machines today—11 years later. No elaborate card system was installed, but the figures were put down in black and white, as witness one method of record herein illustrated. There were no odometers or speedometers in 1902 and the bicycle cyclometer would not last more than a week on a two-ton truck. There was no ampere-hour meter until about 1906. However, by taking careful readings of each machine as it left and returned to the garage, the amount of current consumed in the last trip was determined and if additional current was required for making the next trip, the machines were boosted until the reading showed the necessary amperes.

An accompanying illustration shows two pages of a record book of the Arnold, Constable & Co.'s garage



Record of Trips of Electric Vehicles in the Service of Arnold, Constable & Co., Dated Dec. 8, 1903.

Digitized by Google

that is dated Dec. 9, 1903, which is of much interest from the fact that it demonstrates one of the many conditions that were met with and overcome by the garage engineer. The record was simple enough, but its need and value are apparent. There were no indicating instruments such as are used today, that afford precise information at a glance, and yet the necessity of having this information, especially where exacting service was required, is apparent. Referring to the illustration and taking as an example No. 25 wagon, it will be seen that on the date specified it was taken from the garage at 8 in the morning with the battery reading 95 amperes, and that it was returned at 11:55, when the reading indicated 91 amperes. It was taken out the second time at 1:45 with the battery showing 93 amperes and was returned for the second time at 4:30, when the battery reading was 90 amperes. The wagon was taken out for the third time at 5:30 with the battery showing 93 amperes, and when it was returned at 8:40 the reading was 90 amperes. During the periods when the wagon was in the garage between the trips it was given "boosts" and the capacity so maintained that it was possible to drive it the distances required for the work. This information was kept with reference to each wagon, and aside from the name of the driver no other data were considered necessary so far the charging was concerned. Mileage data were not practical to determine save by estimate. There are 11 of these books in the office of the supervising engineer, in which are kept the operating records of as many years.

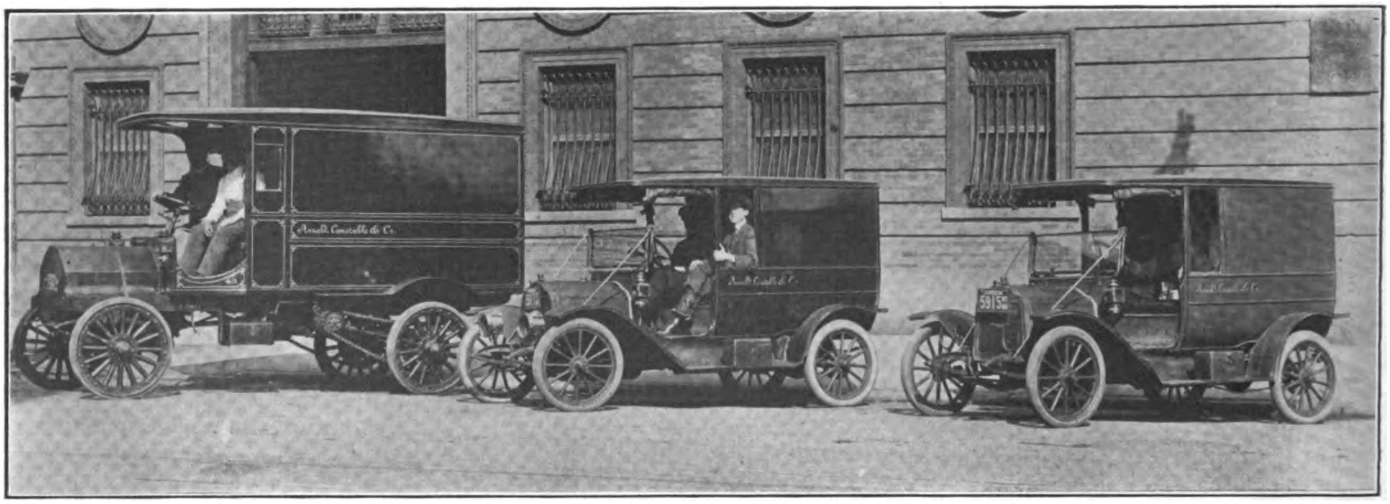
Each driver was required to test his brakes before leaving the garage so that he could not blame all collisions and minor accidents on the wagon itself. Batteries were studied and every weakness corrected as soon as possible. Experiments in routing were made continuously and the almost unbelievable distance of 60 miles a day was made by the light wagons as early as May, 1903. This might mean two short boosts for three trips, but each wagon was required to deliver the goods it started out with and with sufficient nursing it invariably did so.

With all these handicaps the superiority of the electric wagons over horses was soon apparent. They were much speedier, more flexible in heavy traffic and capable of covering far greater distances. They took up less room in the stable and were an expense only when working. In rush seasons and in bad weather they demonstrated their greater reliability as delivery units. And this in 1902.

Then, as now, the wagons left the garage at 8 and reported to the superintendent of delivery at the store at 8:15 sharp. The drivers were recruited from the horse wagons as their knowledge of routes was valuable and again some of them had been with the firm for many years. The men assigned to the 11-year-old wagons seem just as fond of them as they would be of a favorite horse. They take the "kidding" of drivers from other firms with good grace and not infrequently pass them stalled at that. Of course they are quick to appreciate the greater simplicity and other advantages of the newer models and look forward to the time when they, too, will drive the more modern type. The garage men seem divided between a desire to protest at the extra work on the old wagons and a feeling of pride that they have kept them in running order so long. While conceding that the 1902 and 1903 wagons are slow and noisy they will set no date for their being wholly worn out.

So it is a very simple story after all. Once you discover the right principle of operating a well built motor wagon, the rest is a matter of routine. The little things that come up are all in the day's work. Of course if the wagon is not adapted to the work you have a fundamental weakness to start with. The fact that all motor vehicles are machines and should be treated as machinery is important.

The self-propelled wagon requires more attention than its predecessor, but it is worth more—gives a far greater return on the investment. Arnold, Constable & Co. owes its success with them to its recognition of the principle underlying operating efficiency, and others may well give eyes and ears to a careful consideration of this important factor in motor delivery.



Three of the Fleet of Gasoline Delivery Wagons in the Service of Arnold, Constable & Co.

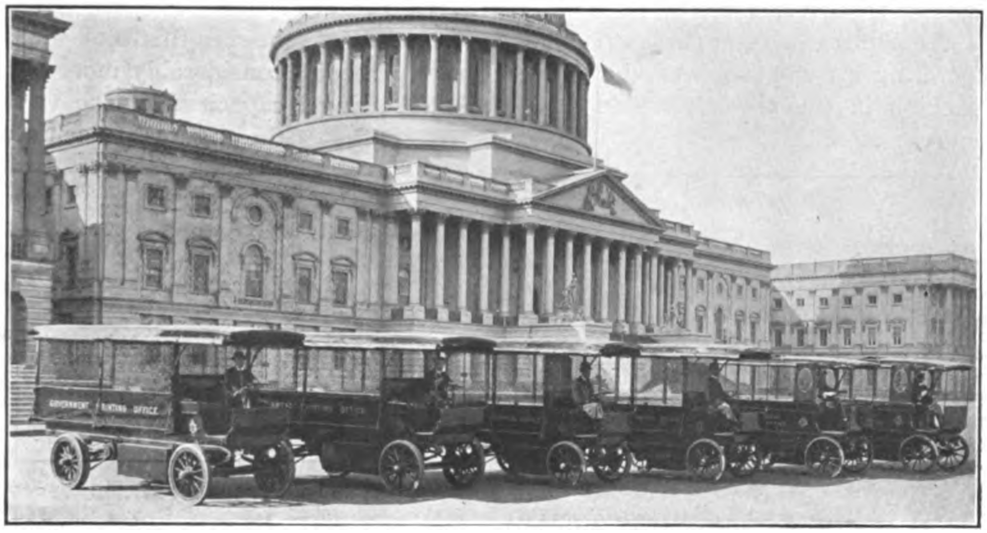
MOTORS SAVE MONEY FOR UNCLE SAM.

THE economy of the installation of Baker electric wagons used by the office of the public printer at Washington, D. C., has been established very effectually by an experience extending over more than a year and a half, and by accounting methods that are practical and certain. Six machines were installed in service in November, 1911, a year later the seventh was delivered, and the eighth was placed in the work in January of this year. From the facts determined there is no question of the saving accomplished as compared with the horse vehicles formerly used, and there is reason to believe that this ratio will be considerably increased.

There are a number of details in connection with the accounting that differ from those usually adopted for business houses. For instance, the government charges interest at 2 per cent., which is approximately 40 per cent. of the rate fixed by commercial practise, the wages paid average more than would be paid in regular delivery service, the work is for eight hours only and it is necessarily less in results, the government makes its own electrical current and there is no charge for this important item, while there is no allowance for garaging.

The equipment of the office originally consisted of 23 horses and a five-ton horse truck, seven two-horse wagons, eight single wagons, three mail wagons and six carriages, a total of 25 vehicles, and these, with harness and accessories, represented an investment of $16,530. In the stable section were employed 23 men, and in the delivery section 19 men, a total of 42, and the wages, rent, feed, supplies, repairs, shoeing and lighting amounted in the year ending June 30, 1911, to $31,231.93, and this, with depreciation allowance and interest, totalled $33,972.03. The total cost of the operation of the delivery section for that period amounted to the sum of $17,256.19.

The subject of motorizing the equipment was carefully studied and it was the opinion of the investigators that the government could save approximately $11,000 a year if electric wagons were used and the horses and vehicles sold. The report was acted upon favorably and in November, 1911, six Baker machines, two of 1000 pounds, two of 2000 pounds, two of 5000 pounds, were purchased, and 17 of the horses and much of the equipment disposed of. In fact the six horses, the five-ton two-horse truck, one heavy single wagon, one two-horse carriage and one single carriage remained, but the service was combination in character. At the expiration of a year a third 5000-pound wagon and an electric carriage were bought, and two carriage horses and one truck horse and the equipment were sold, this leaving but three horses, and when an 8000-pound truck was installed in January of this year two more truck horses were disposed of, this leaving a single horse. Prior to the installation of the electric machines the stable and the delivery departments were each under the supervision of a foreman, but when the motor vehicles were purchased the duties performed by the two foremen were combined and both departments were directed by one man.



Two 1000-Pound, Two 2000-Pound and Two 5000-Pound Baker Electric Delivery Wagons in the Service of the Government Printing Office at Washington, D. C.

Month	Salaries, Wages, Leave of Absence Holiday and Liability Payments Delivery	Stables	Garage	Material and Supplies, Repairs, Etc. Delivery	Stables	Garage
January	$1,429.23	$523.71	$818.23	$14.75	$149.85	$223.87
February	1,330.59	465.88	822.56	2.74	127.06	224.89
March	1,345.76	487.61	828.97	2.28	189.36	240.67
April	1,245.10	484.17	891.61	13.51	76.21	197.08
May	1,378.52	543.23	1,019.64	25.55	114.27	183.87
June	1,141.73	453.61	821.78	66.96	213.18	495.99
July	1,454.96	512.77	887.06	9.40	124.35	173.57
August	1,372.38	447.99	889.27	6.00	127.84	251.64
September	1,487.09	429.50	678.68	4.34	122.55	198.60
October	1,391.65	443.33	710.59	9.94	129.54	307.26
November	1,565.02	337.95	809.68	1.35	57.76	222.40
December	1,460.70	252.00	910.13	13.95	48.81	203.41
Total	$16,602.73	$5,381.75	$10,088.20	$170.77	$1,480.78	$2,923.25
Equipment issued Jan. 1 to Dec. 31, 1912.				$70.00		$24,446.00

Taking the motor equipment now in the service at the market value when purchased the investment represents $29,943, and during the year ending June 30, 1912, the delivery department employees consisted of a foreman, 12 drivers, three helpers, 10 messengers, one mail carrier, two messengers, four stablemen and four drivers, the wage cost amounting to $28,276.96. It is expected that this will be somewhat reduced in the statement for the year just ended.

Some very interesting figures are

shown by the statement on the preceding page of the cost of the stable and delivery from Jan. 1 to Dec. 31, 1912, including salaries, wages, leaves of absence, holiday and liability payments, material, supplies and repairs.

Examples of the work accomplished by the electric vehicles are shown in the following tabulation, these being one of each size of machines, summarizing the principal items and the cost of upkeep aside from the expense of batteries and tires, for there are no charges for these two items:

	1000-lb. Jan.-June	1000-lb. July-Dec.	1000-lb. Total	2000-lb. Jan.-June	2000-lb. July-Dec.	2000-lb. Total	5000-lb. Jan.-June	5000-lb. July-Dec.	5000-lb. Total
Total miles	3,013.00	3,510.00	6,524.00	2,978.00	2,864.00	5,842.00	3,586.00	2,918.00	6,504.00
Ampere-hours	8,598.00	8,459.00	17,057.00	11,019.00	9,710.00	20,929.00	18,302.00	14,096.00	32,398.00
Ampere-hours a mile	2.85	2.40	2.61	3.69	3.38	3.58	5.10	4.83	4.98
Kw-hr. supplied	1,249.8	1,303.80	2,553.6	1,573.6	1,389.4	2,963.00	2,678.4	2,047.8	4,726.2
Cost of current	$14.67	$16.64	$31.31	$18.58	$17.79	$36.37	$31.56	$26.28	$57.84
Battery upkeep	......	......	......	......	......	......	......	......	......
Tire upkeep	......	......	......	......	......	......	......	......	......
Electrical upkeep	1.20	2.93	4.13	0.75	14.38	15.13	5.06	8.67	13.73
Mechanical upkeep	26.80	27.68	54.48	41.34	28.41	69.75	129.62	80.10	209.72
Inspection	161.58	138.67	300.25	161.58	138.67	300.25	161.58	138.66	300.24
Totals	$204.25	$185.92	$390.17	$222.25	$199.25	$421.50	$327.82	$253.71	$581.53

the tires on the 5000-pound machines. They had worn for 13 months and it is probable would have endured for a considerable time more had not these machines been often loaded with 7000 pounds. At the end of the year the tires on the 1000 and 2000-pound wagons were in good condition and were seemingly good for perhaps six months more with normal service. The average load for the 5000-pound wagon is 5500 pounds, for the 2000-pound wagon 2500 pounds, and for the 1000-pound wagon 900 pounds. The average load for a two-horse wagon was 4000 pounds. It will be seen that the endurance of the tires would have been considerably more had the load been restricted to the capacities of the vehicles, for, with the exception of the lightest machines, they have been overloaded. The excellent condition of the streets made this overloading possible without excessive wear, but it is obvious that it was expensive when regarded from the viewpoint of tire cost. The expense for the present year, however, will include new tires, and, in all probability, reconstruction or renewal of the batteries. It is estimated that the cost of operating a 5000-pound electric vehicle is as follows:

An interesting comparison is made of the cost of operating a two-horse wagon and one of each size of machine in the service, which shows the following figures:

	Two-horse Wagon 5000-Lb. Capacity	5000-lb. Electric Truck	2000-lb. Electric Truck	1000-lb. Electric Truck
Average trips a day	4	8	8	9
Mileage a day, average	12	24	20	20
Mileage a month (loaded half way)	312	624	520	520
Average load a trip, lb	4,000	5,500	2,500	900
Total load a day, lb	16,000	44,000	20,000	8,100
Tons	8	22	10	4.05
Total load a month, tons of 2000 lb	208	572	260	105.3
Total cost a month	280.74	211.11	187.81	180.93
Cost a mile	0.899	0.338	0.361	0.347
Cost a mile (omitting driver's and helper's wages)	0.499	0.138	0.121	0.107

Relative to the work of the six machines in use until November, 1912, it is maintained that these did the work that was formerly done by the 23 horses and animal equipment, and that the horses retained practically did the increased work, so that in the government service the machines were actually equal to four horses each. This, however, does not exactly represent facts because of the difference in capacities. The 5000-pound wagons were regarded as easily doing the work of two two-horse wagons, and this in mileage as well as carrying capacity. It will be noted, however, that the figures show that the machines were not by any means worked to mileage capacity, and that as a rule the 1000 and 2000-pound wagons, with battery mileage of from 45 to 50 miles, carrying a half load the whole distance, were driven but 20 miles, assumedly a half of this distance loaded. But if fully loaded they were not worked to develop the greatest economy. As a matter of fact the streets of Washington are extremely well kept and are reasonably level, so that the batteries should give unusual service. Reference to the report will show that the expense for tires and for batteries was nothing, but shortly after the first of the present year it was necessary to replace

Cost of truck and equipment (including spare battery and parts)	$3,745.00	
Maintenance and repair (as per statement above)		$581.53
Depreciation at 10 per cent		374.50
Interest on investment at 2 per cent		74.90
Chauffeur's wages at $2.40 a day		751.20
Messenger's wages at $2.40 a day		751.20
Total original cost	$3,745.00	
Total expense for one year		$2,533.33

The records of the service are very accurately kept. For instance, the battery charging data are kept on a blank that is filled daily, this showing the battery number, date, time, volts, amperes, specific gravity and temperature. The daily meter record shows the numbers of the machines and battery and the date, the readings of the odometer and the ampere-hour meter when leaving and returning to the garage, the time absent and the differences between the two series of entries. Both of these blanks are signed and returned to the office each morning. These data and other facts are entered on the electric vehicle record each month, this

being a summary for the entire year, six months on each side of the card. This gives for each month the total mileage, ampere-hours current used, ampere-hours used a mile, kilowatt-hours supplied, cost of current, battery upkeep, tire upkeep, electrical upkeep, mechanical upkeep and inspection. The work slips of the mechanics furnish the electrical and mechanical upkeep data, and inspection covers washing, labor, charging batteries and general work of a miscellaneous character. Each machine is given a number and all the work, supplies and repairs are charged against each number from the slips and other records. This simplies the accounting and affords all desired facts.

EDISON HEARS SALESMEN.

Head of Big Battery Concern Learns Facts from Men on the Firing Line.

With a view of learning first hand of trade conditions throughout the country, and to formulate plans for the coming year, Thomas A. Edison called to the factory of the Edison Storage Battery Company at Orange, N. J., on July 11, a number of those in charge of the sales of batteries in the principal eastern commercial centres. There was much cause for gratification in the large increase of battery sales since January last, especially of the types used for delivery wagons and trucks, and the statements were that not only were the nickel-iron batteries doing all that was required of them, but the policy of the sales department has been promotive, productive and satisfying to the manufacturers and users of motor vehicles.

Thomas A. Edison and a Group of the Sales-Engineering Executives of the Edison Storage Battery Company at a Factory Conference at Orange, N. J., July 11.

It was stated that despite the unsettled conditions with reference to railroads and to business generally the orders for train lighting and signalling equipment were far in excess of the normal demand; that the use of batteries for house lighting for country homes, where central station current is not available, is larger than for the previous season and is increasing daily; that ignition and lighting batteries are a standard installation very generally used, and a much larger percentage of "replacements" are sold directly to the user. As the utility of the electric vehicle has been recognized in many localities and in practically every climate, the engineering sales force of the company has opportunity to use to excellent advantage, and for the distinct benefit of prospective users of motor delivery vehicles, a large volume of data and figures at its command. The value of accurate and dependable information relative to every class of service is very great and the salesmen have found it greatly appreciated by all considering vehicle equipment.

The accompanying photograph shows Mr. Edison standing in the centre of a group with Vice President and General Manager R. A. Bachman at his right and Manager of Sales William G. Bee at his left. The others in the group include Manager of the Sales-Engineering Department E. J. Ross, Manager of the Railroad Department H. G. Thompson, Manager of the House Lighting Department C. A. Poyer, Assistant Manager of Sales H. R. Leisk, Manager John Kelly of the New York office, Manager C. B. Prayer of the Chicago office, G. W. Holden of Boston and A. O. Heister of Buffalo.

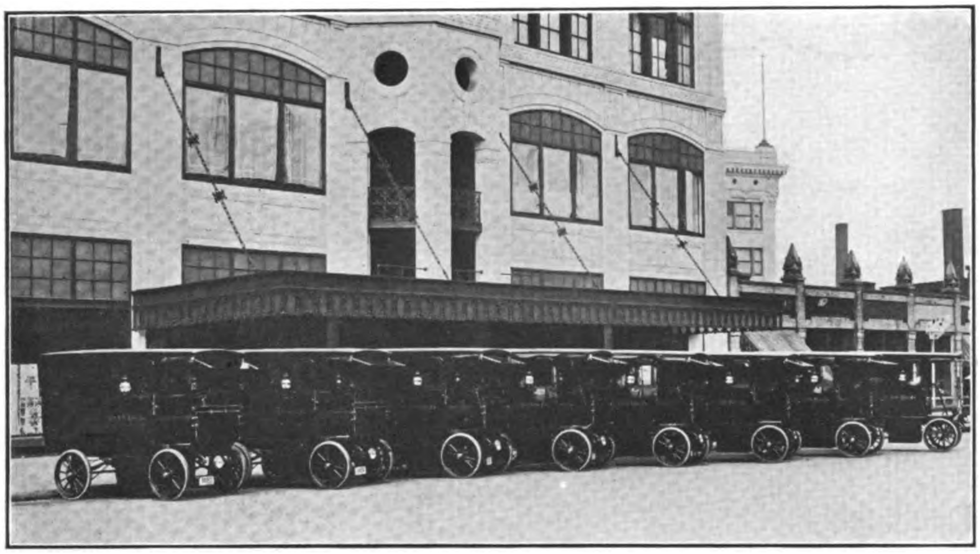
Three buildings of the plant of the Mais Motor Truck Company at Indianapolis, Ind., used for the storage of stock, oil and for general storing were recently destroyed by fire, but the main factory was not damaged and it was in operation the morning following. Aside from a slight delay in shipments there were no serious consequences. The factory has a considerable number of unfilled orders and especial effort has been made to complete these on time, despite the results from the blaze.

A. F. Mais has resigned as consulting engineer of the Studebaker Corporation and will take a rest before associating himself with another well known concern. Mr. Mais designed two Studebaker trucks, which were exhibited at New York last winter and which have been thoroughly tested and developed. These machines have not been produced commercially because of the need of all the factory facilities for producing passenger cars. They were of the internal gear driven type. Mr. Mais also designed the Mais truck, built by the Mais Motor Truck Company, Indianapolis, Ind.

ECONOMY OF MOTOR STORE DELIVERY.

THE experience of the Halle Bros. Company, which conducts a large department store at Cleveland, O., with its fleet of Baker electric delivery wagons, is worthy the consideration of every business man from the fact that the service has been improved materially and the cost considerably lessened. The company makes distribution to its customers in the city and suburbs and had used horse equipment until it was decided to utilize electric motor wagons. Cleveland is a city of large area and it has a fair proportion of good streets, but, like many of the newer municipalities, the improvement of the thoroughfares has not kept pace with the growth. For this reason there is not as great an advantage as might be assumed from the lessened congestion of traffic.

The company when it installed its motor equipment installed a very thorough system of records that it might determine accurately the actual expense of



Eight 1000-Pound Panel Body Baker Delivery Wagons in the Service of Halle Bros. Company, a Widely Known Department Store at Cleveland, O.

the service with a basis of cost a package, and the accounting included the wages of the driver, helper, insurance, depreciation, garaging, repairs, upkeep, and every item that could be logically charged to this department. In connection with this it should be stated that the machines were maintained to a high standard and they are today in splendid condition and are giving the best of results. It may be well to point out that the amortization of electric vehicles is usually fixed at 10 per cent. of the actual cost.

The delivery of every store of proportions will vary materially, and this is well demonstrated with this equipment, but the policy adopted was that when the number of packages was reduced below what was regarded as the minimum that could be profitably delivered, the routes were somewhat increased and one or two of the machines withdrawn from use for the period. This was done in the month of August and allowed the drivers and helpers to have vacations without employing additional help, and it continued the delivery at the desired standard of efficiency.

The result in actual expense is best shown by a summary covering the first year of service, this being an average of work performed that the cost per package might be ascertained. This summary is as follows:

Month	Average Number Packages Delivered Daily	Average Miles Travelled by Each Wagon Daily	Average Cost Packages Delivered (Cents)
November	164	36	4.0
December	247	35	2.7
January	180	33	3.2
February	151	34	4.6
March	191	37	3.8
April	161	34	4.1
May	186	38	3.6
June	161	38	4.2
July	164	37	4.2
August	138	35	5.0
September	156	39	4.6
October	169	38	3.9

These figures show that during the year the average number of packages delivered was 172.33, and the average number of miles driven daily was 36.33, while the average cost of delivery was 3.99 plus cents a package. During December, January, March and May the number of bundles delivered was greater than the average, but during the other months it was less, and the minimum number was in August, when 138 was distributed from each wagon each day. But it should be remembered that this figure was increased a wagon because of two being withdrawn from service during that period. While these machines were laid up the interest and other charges were charged against those in use, this being the fairest distribution that could be made, while, of course, no appreciable depreciation could be credited to these vehicles.

Examination of these figures will show that the cost a package drops in proportion to the volume of distribution, and by reference to the averages for December, when the mileage was below the average and the distribution was 43.6 per cent. more than the average, the cost was reduced to 67.7 per cent. of the average. When the distribution was smallest the cost was 25 per cent. more than the average, and the maximum cost a package was 85.1 per cent. more than the minimum. In other words, it cost 85 per cent. more to deliver a package in August than September, and had the two machines withdrawn been continued in service it is probable that this would have been increased to at least 100 per cent.

Considering the distribution, however, and understanding that the mileage covered does not materially vary, it will be seen that the elasticity of the service

has not been fully realized upon, because the machines have greater mileage capacity than the average shows was necessary. Further analyzing the figures it is evident that the full load capacity of the wagons is by no means reached. Not only this, the wagons can do much more work than is required of them, for they can be kept busy many more hours daily. There is reason to believe that with continued experience the operating cost can be somewhat reduced.

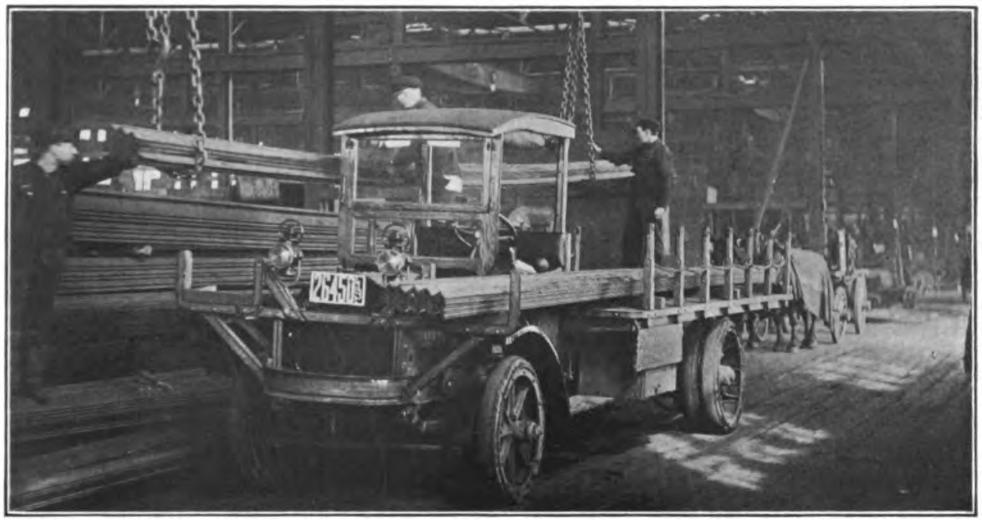
SCIENTIFIC LOAD HANDLING.

Successful Development of Methods Planned for Horses When Motor Trucks Are Used.

Seldom it is that such attention has been directed toward haulage economy that methods the vogue can be continued practically without change when the department is motorized. This means that receiving and delivery had been carefully studied, the conditions analyzed, and the needs for service determined, this with reference to vehicles and to facilities for handling. The Scully Steel & Iron Company of Chicago, Ill., determined to add motor trucks to its equipment, and that these might be used to the greatest advantage a careful survey was made of the different departments to decide what changes would be necessary or desirable in handling the stock, and what form of body would be best adapted.

So well had the stock department been planned and so satisfactory was the equipment that it was believed that only the vehicle bodies need be considered. When the first five-ton White truck was bought a body was built that had the standard stake platform and a frame that made practical the carrying of long lengths of metal. On the deck of the truck are three heavy oak cross members on which the load is placed, there being sufficient space beneath it when resting on the timbers to allow the easy withdrawal of the chain slings. At either side of the front of the truck chassis frame, and braced strongly, is a frame 18 inches wide and 12 inches deep which will support the forward ends of the long lengths of metal. There is sufficient clearance between the load and the hood so that there is access to the engine when the truck is loaded. When these frames are filled there is no load carried in the centre of the platform.

The trucks are driven into the stock department, which has wide aisles between the stocks of metal, and by chain hoists the order is lifted and placed on the trucks. The truck can be placed wherever desired and the hoists are of the trolley type that can be moved the length of the rails on which they are suspended. The accompanying illustration shows a truck on which are 40 long pieces of angle iron, and the same number is hoisted ready for placing on the machine. The construction of the frames supporting the forward ends of the load is clearly seen.



The Stock Department of the Scully Steel & Iron Company, Chicago, Showing the Hoists for Handling Metal and the Special Body Equipment of a Motor Truck.

KISSELKAR IN CALIFORNIA.

Fresno Owner Is Able to Undertake Large Transportation Contracts at Decided Profit.

L. G. Goodrich of Fresno, Cal., offers substantial proof of remunerative results of running a motor truck for hire in California. He owns a three-ton KisselKar, made by the Kissel Motor Car Company, Hartford, Wis., and uses it to haul products for ranchers and fruit growers in his vicinity. Following are some of the recent performances of the vehicle:

Hauling 100 tons of raisins from the vineyard to a packing house 4.5 miles distant, which was accomplished in six days; hauling 2600 orange trees a distance of 18 miles; several loads of bees and honey; turning the machine into a sightseeing car and transporting picnic parties, and general haulage in the city of Fresno.

For this work Mr. Goodrich received from $25 to $30 a day. As to the cost of operating his KisselKar, which he drives and cares for himself, he states that in the 7580 miles it has covered, he has never had a breakdown and but one repair, which was of minor consequence. In hauling the 100 tons of raisins his machine consumed only 12 gallons of California distillate and one-half gallon of cylinder oil. It is still running on its original set of tires.

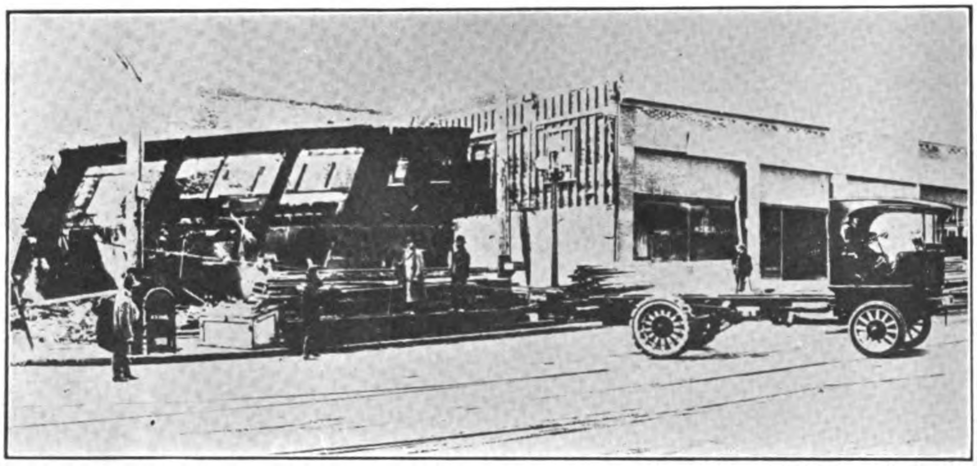
The Cleveland Macadam Company, Cleveland, O., which operates a five-ton White dumping truck in the haulage of crushed stone, has figures that show that the truck earned $500 a month for a period of 4.5 months, when it was constantly in use, it being loaded by gravity and dumped by the power of the engine.

RAZED BUILDING WITH TRUCK.

Garford Machine Used to Quickly Demolish a Structure at Seattle, Wash.

The wide range of service possible and practical with motor trucks is seldom realized, even by those who are constantly using them, and from time to time incidents are brought to the attention of the public which demonstrate how exceedingly useful a machine may be in conditions that were never considered by the most enthusiastic advocate of vehicle utility.

A case in point happened recently at Seattle, Wash., where workmen were demolishing a building and an official of the Waterhouse Trading Company, agent for Garford trucks and pleasure cars, was passing with a truck he was demonstrating. The men had the usual tools and were employing the customary methods to tear the timber apart. They had one wall standing and when this was attacked there was considerable danger because of the possibility of it falling. Safety could only be certain when the side of the structure was levelled to the ground.



The Demolition of a Building at Seattle, Wash., with a Garford Truck by the Waterhouse Truck Company of That City.

The truck salesman volunteered to pull down the wall if a rigging was procured, and so a stout rope was carried around the woodwork at a height sufficient to afford leverage. The other end was made fast to the rear axle of the truck, which was started forward on the lowest speed ratio. The wall toppled in a few seconds and fell, the work was done completely, and the power of the truck sufficiently proven.

MANY DART SERVICE STATIONS.

Distributing Points for Machines and Parts Established for Owners' Benefit.

The Dart Manufacturing Company, Waterloo, Ia., builder of delivery wagons, trucks and motors, is developing an organization that now covers a very large part of the country, it being the intention to afford to all purchasers of Dart machines a service that will be productive of the highest practical efficiency. This includes numerous distributing points, where machines of different types are carried in stock and ample supplies of parts available for owners. These stations are located where they will convenience the largest number using Dart machines, but it is proposed to extend these stations as the business conditions shall justify.

One of the examples of the service is the Dart Motor Truck Company of Massachusetts, Inc., located at 293 Northampton street, Boston, under the management of W. F. Magill. This company covers the New England states, and besides the stock of machines and parts it has a large and well equipped service station and all facilities for undertaking any character of work necessary in connection with the use of Dart wagons and trucks.

The company has announced that it is now ready to make delivery of the types of machines that will be produced for 1914, and in addition to the regular features, some of which are exclusive, the customers can have installed as extra equipment electric starting and lighting systems. The systems are not included as regular as there has been no change in the prices, and the high standard of material and workmanship is maintained. The company has adopted a selling policy that is expected to be promotive and benefit the small business men who might not feel disposed to take from their working capital at one time the cost of a machine. The company will make sales on a basis of one-third of the purchase price with the order, and the remainder may be paid in monthly installments.

The Dart Motor Sales Company, Mount Vernon, N. Y., has the agency for Westchester county in that state, and has already developed a substantial business, and the Dart Pennsylvania Branch at Butler, Penn., is the distributing point for the western half of Pennsylvania. Here an up-to-date service station has been established with full facilities and stocks of machines and parts. Contract has been made with the George Siegmund Company, 2025 Michigan avenue, Chicago, Ill., for the distribution of machines for the Central states and the maintenance of a high class service station, and there are other distributors in Los Angeles, San Francisco, Denver, Omaha, Minneapolis and St. Louis. In all of these points are direct representatives of the company, who can give attention to any requirement and guarantee service that will be satisfactory.

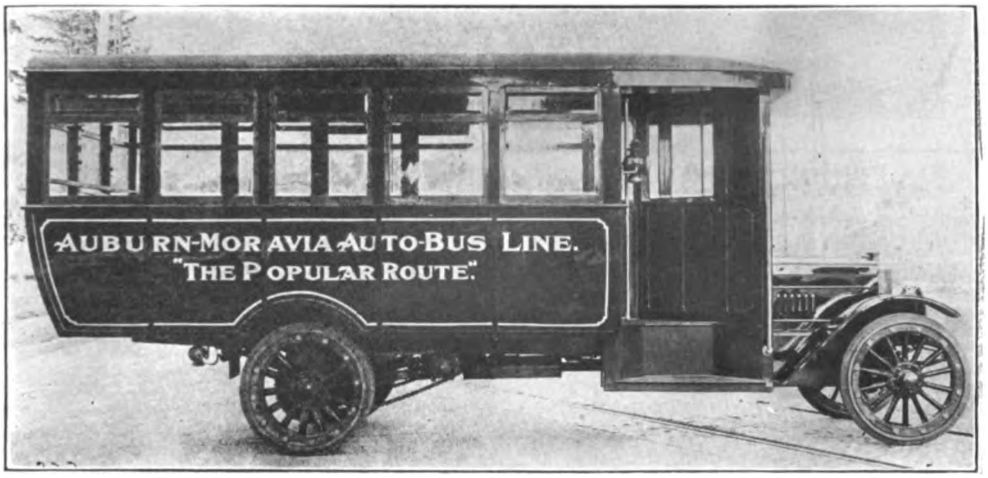
The Massachusetts law, which limits the weight of a motor truck and its load to 14 tons, and the weight of any vehicle to 800 pounds per inch of tire width, is now effective.

PAY-AS-YOU-ENTER MOTOR 'BUS.

Cleverly Designed Body Installed on a Two-Ton Atterbury Truck Chassis.

An automobile omnibus service has been established between Auburn and Moravia, N. Y., that affords the people of the two communities and of the section between them the first direct transportation they have ever had. The company is known as the Auburn-Moravia Auto-'Bus Line and it is using as its initial vehicle a two-ton Atterbury truck chassis on which is installed a cleverly designed body that will seat 25 passengers. The distance between the terminals is 23 miles and the fare is 50 cents, this being such as to induce a very satisfactory patronage. It is purposed to have the service permanent.

The omnibus is fitted with a body specially designed for the work, and it is what might be termed as car construction, with a single entrance, the passengers paying fares as they enter. As will be noted from the illustration the door is at the right side and this occupies half of the space that would ordinarily be taken for the footboards and driver's seat, there being a partition that extends diagonally from the dash to the front of the body. At the left side of this partition is the seat for the driver, the steering wheel and other control members, and the space for the driver can be enclosed in severe weather by a permanent windshield and a side curtain.



The Pay-As-You Enter 'Bus on Atterbury Two-Ton Chassis Built for Service Between Auburn and Moravia, N. Y., Having Capacity of 25 Passengers.

The body has five windows at either side, two rear windows and a window in the door and behind the driver, thus affording a full view in any direction, and these may be dropped in warm weather. The windows are curtained and between each window is a push button to signal the driver. The interior of the body is finished in the natural wood, this making for cleanliness, and the seats are of the street car type, each accommodating two, five at the right side of the body and six at the other, with a longitudinal seat at the right side of the door. The seats are very comfortably upholstered. The car is designed to stand with the right side to the curb and there is a single step that takes the place of the usual running board, there being hand rails at either side of the door. Short fenders cover the front wheels and the body is cut away over the rear wheels, the recess permitting the movement of the body and giving the necessary clearance. The body is ventilated by floor gratings. The lighting is by dome lamps in the body and side lamps at either side of the body. The chassis is a model C and is equipped with a four-cylinder motor that is rated at 40 horsepower.

FOUR CENTS A TON-MILE.

Baldwin Locomotive Company Operates 10 Five-Ton Saurers as Private Express Line.

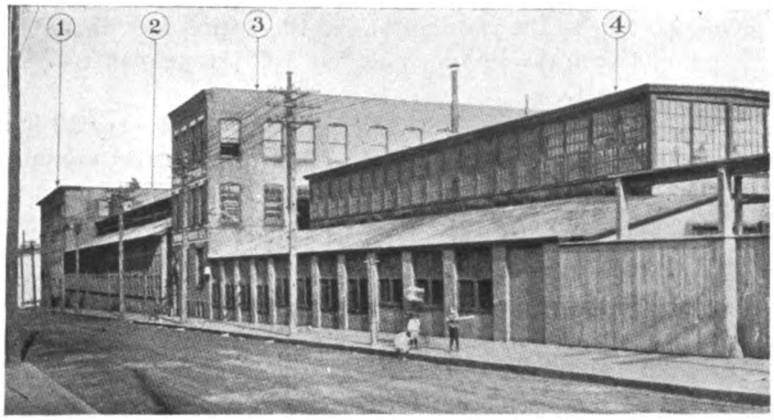
The fleet of motor trucks being operated by the Baldwin Locomotive Company, Philadelphia, Penn., has practically given the concern a private express line. The company originally purchased four five-ton Saurer trucks, made by the International Motor Company, New York City, and after operating them with the closest scrutiny gave a repeat order of six more of the same type. With the exception of an occasional trip to the railroad yards, the entire fleet operates between the Philadelphia and Eddystone plants, 13 miles apart.

Each truck makes two round trips every 12 hours, night and day, plus several miles of travel around the plants, taking on and discharging loads, making an average of 60 miles instead of 52. The machines are loaded, going and coming, generally to capacity, or 10,000 pounds, making 20,000 each round trip; 40,000 pounds carried every 12 hours; 80,000 pounds every 24 hours, year in and year out. As it costs the Baldwin company, according to its own figures, $12 a 12-hour day to operate each truck, this gives an expense of four cents a ton-mile.

This is a year of versatility of the motor truck and making one machine do the work of three, four and even five, is now the aim of the commercial vehicle builder. Contractors have peculiar lines of work and they have consulted with the engineers of automobile factories with a view of having service and efficiency greatly increased. Recently the Moreland Motor Truck Company, Los Angeles, Cal., delivered to a contractor a five-ton, 60 horsepower Moreland truck, with three bodies. The machine was equipped with dump and box bodies and a tank. These were interchangeable within 15 minutes and by this plan it gave the buyers practically three trucks at little more than the expense of one.

BRIEF NEWS OF MANUFACTURER AND THE TRADE

An opportunity for the establishment of an immense motor truck garage and repair shop has been created by the abandonment of the Providence, R. I., plant of the General Fire Extinguisher Company and the concentration of the business at Auburn, R. I., for this property, especially adapted for manufacturing purposes, is splendidly located in the centre of the wholesale, warehouse and manufacturing section of the city. The plant consists of five buildings having frontage of 507.82 feet on Exchange street, and the land has frontage of 219.30 feet on Bradford street and 257.12 on Cedar street, the area being 84,664.46 square feet. Four of these buildings have direct communication with each other, and the fifth is connected by two overhead passages. Building No. 1 is of brick, having heavy construction, three stories and high basement, 113.2x75.2 feet; building No. 2 is a high brick and frame foundry structure, splendidly built, 199.6x75.2 feet; building No. 3 is three stories and high basement, of brick, heavily constructed, 33.2x110.7 feet; building No. 4 is a brick and frame foundry, with monitor roof, about 120x55 feet; building No. 5 is a single story brick and stone structure 312.3x25feet, this being separated from the main buildings, but connected by two passages. The buildings are piped for steam heat and equipped with a Grinnell automatic sprinkler system, the latter affording very low insurance rates. The property is convenient to every business section of Providence and would be ideal for a garage and repair shop from every practical aspect, and is equally suited for any kind of manufacturing. Every information, illustrative and descriptive, can be obtained from G. L. & H. J. Gross, managers of estates, 170 Westminster street, Providence. The property will be sold as a unit, or divided into nine parts, on five of which are buildings. The buildings have a floor area of approximately 78,000 feet, and there is sufficient space unoccupied by structures to meet almost any character of expansion without adding to those now standing, if it would be desirable to retain them in their present form.



The Buildings of the Plant of the General Fire Extinguisher Company in West Exchange Street, Providence, R. I.

The Anderson Rolled Gear Company, Cleveland, O., maker of automobile and other gears, is incorporated with a capital of $100,000, and it is reported, will move to Toledo, O., in the near future. N. Anderson of Cleveland is president and A. Barker of Toledo is vice president.

The Pope-Hartford Company of Boston, Boston, Mass., distributor of Pope-Hartford trucks and pleasure cars, has found it necessary to erect a large addition to the already extensive service station on Hayward street, Cambridge, Mass. The new building will have every modern convenience for housing and caring for cars, and also the latest facilities for conducting quick and strictly first class repairs.

The Brown Automobile Company, St. Louis, Mo., for several years representative of the Peerless Motor Car Company, Cleveland, O., maker of Peerless trucks and pleasure cars, has been absorbed by the Peerless Motor Car Sales Company. Oscar Stroh is president of the new concern and F. G. Weaver will be secretary, treasurer and manager, positions he has held for 11 years with the Brown and Peerless companies. Mr. Stroh and Mr. Weaver have purchased the interests of J. R. and C. F. Brown and the business will be conducted along the lines that have already become well known.

Allan W. Fulton & Co., 720 East Pratt street, Baltimore, Md., has taken the agency for the Lauth-Juergens motor trucks, made by the Lauth-Juergens Motor Car Company, Fremont, O.

The Machine Manufacturing & Engineering Company, Council Bluffs, Ia., maker of automobile supplies and accessories, has plans to enlarge its business.

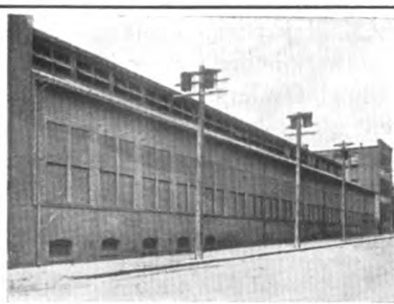
The Twin City Motor Car Company, St. Paul, Minn., northwestern distributor of Saurer, Mack and Modern trucks, and Maxwell pleasure cars, has moved into new quarters at 163 West Sixth street.

Charles E. Chadwick, one of the organizers of the Brockway Motor Truck Company, Cortland, N. Y., maker of Brockway trucks, has severed his connection with the company.

Clyde Thompson, formerly manager of the advertising department of the Diamond Rubber Company, Akron, O., maker of Diamond tires, recently taken over by the Goodyear Tire & Rubber Company, Akron, maker of Goodyear tires, has resigned.

The Velie Motor Company of Missouri, 5143 Delmar boulevard, St. Louis, Mo., announces the appointment of A. P. Bartlett as general manager of the newly incorporated company. Mr. Bartlett's experience in the retail automobile business in St. Louis extends over many years, and with W. J. Carter and C. F. Swartz to assist him, Velie owners in that territory will recognize in a very substantial way that the concern is most progressive. A new salesroom has been constructed and the office has also been re-equipped. A specialty of service to owners of Velie cars will be made.

Building No. 1.



Building No. 2.

Building No. 3.

Three of the Four Structures That Constitute the Main Property of the General Fire Extinguisher Company.

The Lewis Spring & Axle Company, Jackson, Mich., has absorbed the Lee & Porter Manufacturing Company, Buchanan, Mich.

R. C. Chase has resigned from the advertising department of the Packard Motor Car Company, Detroit, maker of Packard trucks and pleasure cars.

The W. J. Hughey & Son Company, Chicago, is building a factory for the manufacture of motor trucks at Prairie avenue and 33d street, to cost $100,000.

The Moreland Motor Truck Company, 1701-1731 North Main street, Los Angeles, Cal., is enlarging its plant, the new buildings costing $250,000.

Thomas R. O'Brien, maker of motor truck bodies, carts, etc., has secured larger quarters at Hubbard avenue and Dale street, Springfield, Mass.

H. H. Murden has been appointed factory manager of the Knickerbocker Motor Truck Manufacturing Company, New York City.

C. K. Thomas has been appointed manager of the Federal Truck Company, New York City, distributor of the Federal line, made by the Federal Motor Truck Company, Detroit.

R. M. Laird, Athens, O., has started an automobile 'bus line between Chillicothe and Bainbridge, O., with two large cars capable of seating 20 persons each.

The Monitor Automobile Works, Janesville, Wis., has ceased the manufacture of its two-cylinder model and in future will make its four-cylinder trucks exclusively.

C. H. Harvey has been appointed sales manager of the Eastman Motor Car Company, Philadelphia, Penn., distributor of Wilcox trucks, made by the H. E. Wilcox Motor Car Company, Minneapolis, Minn.

The Dreadnaught Tire Company, Baltimore, Md., has acquired a plant at Orangeville, Baltimore county, which is located on a four-acre site. It is being rebuilt for tire manufacture.

The Mogul Motor Truck Company, Chicago, maker of Mogul trucks, has leased a factory building at Maple avenue and the Wabash railroad, St. Louis, Mo., to which place it will move its plant.

The Gramm Motor Truck Company, Lima, O., maker of Gramm trucks, is to increase its facilities in the near future, according to an announcement made by President John N. Willys.

The Universal Motor Truck Company, Detroit, maker of Universal trucks, has begun work on a new addition to its factory. The plant will be practically doubled and the cost of the new buildings will be $250,000.

George W. Edwards, well known in St. Louis, Mo., has become manager of the St. Louis branch of the General Motors Truck Company, Pontiac, Mich., maker of G. M. C. trucks, with headquarters at 2815 Olive street.

Joseph Q. Goodie, who has been manager of the Detroit branch of the Diamond Rubber Company, has been appointed sales manager for the Pennsylvania Rubber Company, Jeannette, Penn. His headquarters will be at Detroit.

Charles Fisher, formerly Chicago manager of the Universal Motor Truck Company, Detroit, maker of Universal trucks, has been promoted to district manager and will handle the Middle West territory. He is succeeded at Chicago by C. P. Derr.

The Hendrie Rubber Company, Torrance, Cal., has practically completed its new plant, which cost $100,000, and the Pacific Electric Railway has commenced the construction of a special line to serve the plant.

R. S. de Milkiewicz, who has been connected with the truck department of the Peerless Motor Car Company, Cleveland, O., has resigned to affiliate with the New York City branch of the American Locomotive Company, maker of Alco trucks.

The Brady-Murray Corporation, New York City, has moved into its new quarters, having leased the first two floors of the 11-story building at 245 West 55th street. The company handles the Maccarr, Lansden electric and Smith commercial vehicles.

The General Motors Truck Company, St. Louis, Mo., is erecting a large service station and space is being made to accommodate 40 trucks, with an entrance to the building large enough to admit a five-ton machine. It is the first commercial vehicle garage to be established at St. Louis.

The Philadelphia Truck Association, recently formed, has held its first meeting and motor truck matters were discussed. The committee on publicity was instructed to issue a club organ. James Reed, Jr., assistant director of public works, Philadelphia, and E. S. Foljambe were the speakers at the meeting.

Fred Roble, formerly manager of the International Motors Company, Chicago, has resigned.

The Britton-Stevens Motor Corporation, Boston, Mass., has taken the agency for the Maccarr and Smith-Milwaukee motor trucks.

The Holcomb Company, New Haven, Conn., has taken the agency for the Adams trucks, made by the Adams Bros. Company, Findlay, O.

Frank N. Sim has become assistant advertising manager of the Timken-Detroit Axle Company and the Timken Roller Bearing Company.

George F. Russell has succeeded Joseph D. Porter as advertising manager of the Garford Company, Elyria, O., maker of Garford trucks.

The A. G. Hebb Auto Company, Lincoln, Neb., has taken the agency for the Chase truck, made by the Chase Motor Truck Company, Syracuse, N. Y.

The C. B. B. Motor Company, Washington, D. C., has taken the agency for the Selden truck, made by the Selden Motor Vehicle Company, Rochester, N. Y.

Gilardi & Faure, Sacramento, Cal., is representing the Kelly line of trucks, made by the Kelly-Springfield Motor Truck Company, Springfield, O.

C. E. Osborn has charge of the new service department of the Speedwell Motor Car Company, Dayton, O., maker of Speedwell trucks, at Van Ness avenue, San Francisco, Cal.

George Davis has become manager of the Dominant Motor Car Company, Buffalo, N. Y., agent for Packard trucks, made by the Packard Motor Car Company, Detroit.

Charles B. Warren, formerly general manager of the Haynes Automobile Company, Indianapolis, Ind., has become manager of the New York City branch of the General Motors Truck Company, maker of G. M. C. trucks.

R. K. Johnston, formerly of the Gramm Motor Truck Company, Lima, O., maker of Gramm trucks, has been appointed general manager of the Bowling Green Motor Car Company, Bowling Green, O., manufacturer of the Modern truck.

F. A. Calderwood, formerly assistant manager of the Lozier Motor Company of New England, Boston, has taken a similar position with the Boston branch of the Locomobile Company of America, Bridgeport, Conn., the maker of the Locomobile truck.

W. F. Wittenberg has been appointed manager of the Nevada Manufacturing Company, Nevada, Ia., a concern which has been formed to manufacture motor trucks and motor plows. Mr. Witttenberg was formerly sales manager of the Christian Engineering Company, Milwaukee, Wis.

The Milwaukee Tire & Supply Company, Milwaukee, Wis., has been appointed local agent for White pleasure and commercial cars, made by the White company, Cleveland, O. The new company will be known as the White Automobile Company, Milwaukee Tire & Supply Company, owners.

The Kentucky Wagon Manufacturing Company, Louisville, Ky., recently held its annual meeting. W. O. Harris, Jr., and Stuart E. Duncan were elected directors to succeed C. G. Strater and L. Allen. President W. C. Nones was re-elected, as were also the following directors: S. M. Nones, John Marshall, John C. Hughes, Bernard Bernheim, P. S. Tuley and James Glazebrook.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC.

Of **The Motor Truck**, Published **Monthly**, at **Pawtucket, Rhode Island**, required by the act of August 24, 1912.

NOTE—This statement is to be made in duplicate, both copies to be delivered by the publisher to the postmaster, who will send one copy to the Third Assistant Postmaster General (Division of Classification), Washington, D. C., and retain the other in the files of the postoffice.

MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.

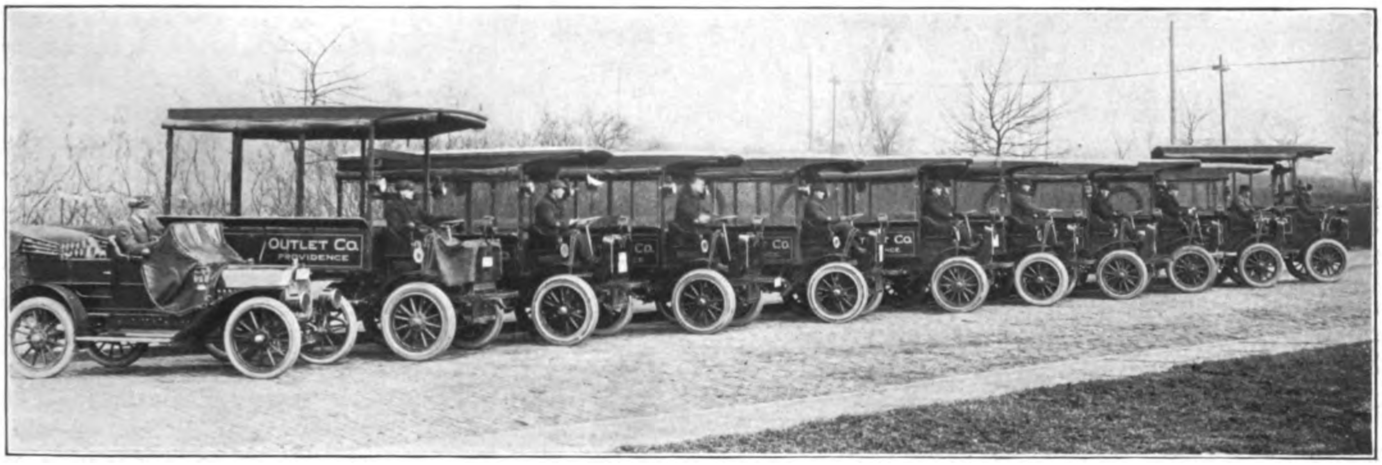
VOL. IV. PAWTUCKET, R. I., AUGUST, 1913 No. 8

HOW MOTOR WAGONS DEVELOP BUSINESS.

The Transportation Conditions in the Commercial Centre of Moderate Size and the Manner in Which Department Stores and Large Groceries Serve Customers Within a 15-Mile Radius—The Possibilities of Motorized Equipment.

By William W. Scott.

THE analysis of the transportation conditions in Boston and its suburbs, made by the MOTOR TRUCK, demonstrated the enormous duplication of service and the competition in systematized haulage. Turning from this locality to one of lesser proportions, Providence was selected as being the second largest city in New England, having the advantage of both water and railroad facilities and being a centre of distribution for central New England. Providence has a large coastwise commerce, it is one of the most prosperous of manufacturing communities, and it is especially advantageously located for competition with Boston.



Ten of the Fleet of 14 Machines Operated by the Outlet Company, Providence, R. I., Two of Which are Fitted for Furniture Delivery, 10 for Parcels and Two for Special Service.

Providence is the commercial centre of Rhode Island, eastern Connecticut and central and southwestern Massachusetts. In this territory is a population of approximately 750,000. The line of demarcation may be said to be drawn to include the city of New Bedford at the southeast, and this line carried northeast will include the towns of Dartmouth and Eastport, the city of Fall River, the towns of Freetown and Berkley, the city of Taunton, the towns of Dighton, Swansea, Rehoboth, Norton, Attleboro, North Attleboro and Plainville, and another line carried west would take in the Massachusetts towns of Wrentham, Bellingham, Blackstone, Uxbridge and Douglas. From this point south the line will take in a section of Connecticut about 15 miles wide.

From Providence lines of railroad reach New Bedford via Taunton, Fall River, Worcester, Mass.; Pascoag, R. I.; Hartford and New London, Conn., and and Boston via Attleboro and via Wrentham, and to Newport. In addition there are trolley lines to Fall River and New Bedford, Taunton, Attleboro and North Attleboro, Blackstone, Danielson, Newport and Narragansett Pier. There is a network of transportation lines from practically every locality within the state and to central and southeastern Massachusetts, and one trolley line and two railroads into Connecticut.

The following tabulation gives the population of the towns and cities that may be considered as accessible from Providence by delivery and where the trade is sufficient to justify distribution, Providence having

by close estimates about 240,000 inhabitants.

North	
Pawtucket	55,000
Central Falls	27,000
Cumberland	11,000
Lincoln	10,000
Woonsocket	40,000
North Providence	6,000
Northeast	
Plainville	5,000
North Attleboro	10,000
Attleboro	18,000
East	
East Providence	17,000

Coventry	4.0	17.6
Northwest		
Centerdale	4.9	
Greenville	3.5	8.4
Harmony	2.5	10.9
Chepachet	4.5	15.4

Reference to the first tabulation will give the name of the towns and cities, beginning with those nearest to Providence, and the second gives the names of the different cities and villages on the main highways, but this does not include very many village or locality designations that may be included within these towns and cities that are very generally recognized.

Rhode Island is the most densely populated state of the nation and the greater part of its 550,000 inhabitants are in six cities and six towns, less than 10 per cent. of the population being in the remaining 27 towns. The western half of the state is really sparsely inhabited, and aside from Newport and the town of Westerly, the greater part of the population is within a radius of 20 miles from Providence. From the Massachusetts line south through the Blackstone river valley and on either side of Narragansett bay, and in the Pawtuxet river valley, the cities and towns are so close that there is hardly a line of demarcation between them. This 20-mile radius will extend over the Massachusetts line and include the towns of Seekonk, Attleboro, North Attleboro and Plainville, and it will reach the boundary of Fall River.

Either shore of Narragansett bay is practically populated by summer colonies, and in these towns a considerable number of people have country homes, where they reside throughout the year. From early spring until well into the autumn the number of residents is largely increased. But the patronage of those who have suburban homes is sufficient to justify the maintenance of daily delivery by some of the large business houses of Providence.

As might be assumed the most regular delivery is by the large department stores of Providence, of which there are four, while two of the principal groceries have services that are even more regular, because supplies of food are absolutely essential and must be delivered promptly because of the perishable character of a considerable portion of the orders.

From the viewpoint of the student of transportation conditions in Rhode Island there is wide va-

riance with those obtaining in Boston. There are in the state 80 different express services, including the Electric Express, the Adams Express Company, the Boston, Providence & Fall River Express and the New York & Springfield Express. Of the 76 companies or services 41 are located in Providence, 10 in Pawtucket, five in Newport, three in Narragansett Pier, one each in Woonsocket and Wickford, two each in Warwick Neck and Warren, three in the Pawtuxet Valley, one in North Attleboro and seven in Attleboro. Some of these companies do general contract haulage and others have regular services between Providence and some of the towns and cities. As a rule, however, comparatively little work is done by these companies for the stores of large size, but a considerable volume of transportation is done by them for the numerous manufactories.

There is practically little system so far as the express service is concerned. The majority of the companies have offices where orders may be given by telephone, and in several instances have stations where goods may be received, but the greater number serve regular customers and make calls for collection and delivery. Some of the companies have times of departure, fixed for the convenience of the customers, but no attempt is made at systematic service, as provided by Boston transportation concerns.

There is a greater number of houses that make their own deliveries than there is in Boston, in proportion to the business done. Of these the department stores and the furniture dealers will deliver anywhere in New England, provided the order is of sufficient size to warrant this expense. All of the department stores utilize motor vehicles and the use of these has practically eliminated the service of the express companies, and it has made possible regular deliveries in a much greater radius than ever before. Not only has the expense per package been lessened materially, but direct dealing with the customers has given a much greater degree of satisfaction. By this is meant that the stores have control of their own men and equipment, which they did not have with contract delivery, and in the event of loss the cause is easier to trace and the adjustments can be made much more satisfactorily.

The Outlet company, which has a very large store, does not deal in meats, groceries or food products, but handles all kinds of dry goods, men's and women's apparel, house furnishings, furniture, etc. The company's store is practically all of the square bounded by Weybosset, Eddy, Pine and Garnet streets. Weybosset street is the widest business thoroughfare of the city and the other streets are comparatively narrow. This company is just completing a new building that will have 75,000 square feet of floor space, which it has not as yet occupied, and it is planning extensive changes that will probably be completed before the end of the year.

This company is especially favored in the fact that a larger proportion of the sales are taken from the store by the purchasers than is the experience of the other stores, and this minimizes the requirements as to delivery equipment. The company now has in service 12 Autocar delivery wagons of 3000 pounds capacity, two of which are fitted with furniture bodies; two Ford chassis fitted with tops and express bodies, and five horse wagons. This makes a total of 19 vehicles in regular use, while there is also a specially equipped wagon that is used for the delivery of gas and coal ranges, etc. Horse equipment was used exclusively until December, 1909, when the first motor wagon, an Autocar, was purchased, and this was utilized in

Sorting the Packages and "Stacking" the Motor Wagons for the Shepard Company in Washington Street, Providence, R. I., in Preparation for the Suburban Delivery.

suburban delivery. The company had not until that time sought to make deliveries outside of Providence, Pawtucket and Edgewood, but this was the beginning of an era of delivery expansion and improvement, and the development of a decidedly superior service.

The work accomplished was what would have hardly been done with horses, and it would be impractical to make direct comparison with animals. Later on other machines were purchased and the number of horse wagons reduced, the purpose being to improve the delivery outside of the compact portion of Providence; working the horses where they could be used to the best advantage they were found to be more economical.

A word of explanation relative to the topography of Providence may be interpolated. The East Side, so-called, is a tongue of land extending south between the Blackstone river on the east and the Providence and Moshassuck rivers on the west, from the Paw-

tucket line. This tongue has a ridge close to the west side that rises at its extreme to a height of 210 feet. The streets run generally north and south and east and west, and the ascents from the west side are very steep, in some instance the grades being 15 feet in 100. The south end of this ridge is known as College Hill, and the northern portion Constitution hill. The West Side of the city is much the larger and it is encircled by Smith, Fruit, Federal, Constitution and Willard's hills and Mount Pleasant, the last named being the highest. Aside from Mount Pleasant the grades are not what may be regarded as heavy. These hills are in reality heights, and when ascended the highways are comparatively level. The streets of Providence are excellent, there being granite block paving in many of those where there is heavy traffic, with asphalt and macadam in the greater part of the residential thoroughfares. There are some gravel streets and some that are not improved.

Outside of Providence, in practically every direction, there are no heavy grades, and in the different

The Delivery Wagons of the Shepard Company in Clemence Street, Showing the Conditions of This Highway for Loading and Starting.

towns and cities the streets are generally very good, while the main or connecting highways, in which there is the greatest volume of traffic, are excellent. In the towns of the state highways are well maintained and these may be said to be better than the average state road outside of Rhode Island.

The motor delivery equipment of the Outlet Company is now kept at the service station of the Autocar Company in Pearl street, approximately three-quarters of a mile from the store. It is under the supervision of a practical mechanic who sees that the machines are maintained to the required standard. The company pays a regular service charge and beyond this maintenance is paid for whatever work is performed, this varying with requirements. The regular oiling, greasing and adjusting of the machines is done at the garage under the direction of the superintendent of the equipment, but the drivers are expected to fill the fuel and oil tanks and the radiators. This is practically all the attention they are required to give. The machines leave the garage mornings at 7:30 and are expected to reach the store at 7:45, and there the loading is in Pine street, all of the packages being taken from the shipping department through a small court from the rear of the main store building.

The suburban wagons are first loaded, or at least these have a right of way, and for this suburban work five machines are utilized. The first delivery is started about 8:30. The five suburban Autocars make one trip a day and the load as a rule is heavy. One of these takes in East Providence, Barrington, Warren and Bristol, as well as Seekonk, reaching the localities known as East Providence Center, Phillipsdale, Rumford, Kettle Point, Bay View, Boyden Heights, Silver Spring, Riverside, Camp White, Narragansett Terrace, Drownville, West Barrington, Nayatt, Barrington, Hampden Meadows, Warren, South Warren, Beach Terrace, Bristol Highland, Bristol and Bristol Neck. This is the East Shore route.

The West Shore route begins practically at the city line and goes south, reaching Palace Garden, Spring Green, Hoxsie, Cole's, Riverdale, Conimicut, Shawomet, Riverview, Long Meadow, Grant's, Highland Beach, Tiffany, Rocky Point, Oakland Beach, Buttonwoods, Apponaug, Hillsgrove, Lincoln Park, Norwood, Greenwood, Coweset, Chipiwanoxet and East Greenwich. A third route goes southwest and through the Pawtuxet valley, reaching Knightsville, Meshanticut Park, Oaklawn, Sockanosset, Howard, Pettaconsett, Pontiac, Natick, Westcott, River Point, Clyde, Lippitt, Phenis, Harris, Arkwright, Fiskville, Hope, Arctic, Centerville, Jackson, Crompton, Quidnick, Bakersville, Anthony and Washington.

The fourth route goes west and reaches Manton, Lymanville, Centerdale, Graystone, Esmond, Georgiaville, Stillwater, North Providence, Fairlawn in the city of Pawtucket, Saylesville, Prospect Hill and West Lonsdale in the town of Lincoln, and Berkeley and Ashton in the town of Cumberland. The fifth route is north and east and reaches all of Pawtucket except Fairlawn, Central Falls, Valley Falls, East Lonsdale, St. Jean, South Attleboro, Hebronville, Dodgeville, Attleboro Falls, North Attleboro, Plainville.

Considering this service it will be understood that it extends outward 16 miles on the East Shore route, 13 miles on the West Shore route, 14 miles on the Pawtuxet valley route, 10 miles on the west and northern route, and 15 miles on the Attleboro route. These are covered once daily and the distances driven will average from 65 to 70 miles. Of the other machines, one is reserved for special service, two are given over to furniture delivery, three are used for making regular city delivery, making three trips, and one covers Edgewood, Pawtuxet, Pawtuxet Neck, Lakewood, South Auburn and Auburn, making two trips. This will account for the 12 Autocars. Aside from the regular suburban service the delivery in Pawtuxet requires a mileage of about 50, and the three machines used in the city will make an average of about 16 miles each of the three trips. Besides the motor vehicles three

horse wagons are used in the central section of the city where the deliveries are numerous and the stops close together.

Up to four years ago the delivery of this store with its own equipment was practically within the city and Pawtucket, and at most was within a radius of four miles. Of course in exceptional cases and in the event of sales of furniture deliveries were made much greater distances, but this may be applied to the regular distribution of parcels. Beyond that radius delivery was made by express companies. At that time the company used about 45 horses and from 20 to 25 wagons. In the delivery work where three trips were made daily the average driven was about 35 miles, one trip in the morning and two in the afternoon, the morning delivery being heavy and the afternoon trips comparatively lighter.

The reduction of the horse vehicles to three and the use of the motor wagons has afforded a practical and satisfactory delivery in an area that is approximately 12 times as large, and the number of express services has been reduced to two, one to Woonsocket and the other to the summer colonies between Warren and Fall River, to Fall River and to New Bedford. There is really no limit to the delivery of furniture, and an order of sufficient size will be taken 200 miles if necessary. Deliveries are frequently made up to 50 miles. The special service machine is on call for long or short trips as required, but it is used for the delivery of refrigerators in summer and for ranges and gas stoves in winter. This machine has been sent to New London in one direction and to Cambridge, Mass., in another, these being trips of 70 and 50 miles respectively.

One of the Ford wagons is equipped for the use of a shade and awning crew that carries tools and stock for practically any condition that may eventuate, and the other Ford machine is similarly equipped for a carpet-laying crew. With these the men are carried about quickly, their time is economized, and the stock is always ready without delays. The company has a wagon fitted for the delivery of stoves, gas ranges, etc.

The Autocar wagons are fitted with longitudinal seats, well cushioned, and each Friday afternoon during the summer, when the store is closed, the children of all the orphanages in Providence and vicinity are taken for an outing as the guests of the company. The drivers, who have to drive the wagons, and lose their half holiday, are paid double time for their work. Arrangements are made to visit each orphanage in turn, with the number of machines that may be needed, and the children and their attendants are taken out sometimes 20 miles to a point where they can have a feast of ice cream, cake, candy, etc., the refreshments being carried in a car. The plan is to give them three hours on the road and a half hour to an hour at the outward end of the journey.

Members of the company say that the motor wagons have sufficiently proven their utility and economy for all kinds of suburban work, and for portions of the city where the grades are steep. In fact, it is the intention of the company to dispose of all its horses and it is probable that within a year the delivery equipment will be completely motorized. They believe that electric delivery wagons will better serve the purposes of the company in the portions of the city where the routes are comparatively short and the stops are frequent because of the ease of stopping and starting. They favor their use where a package must be delivered every one and a half or two minutes, because of the need of cranking the gasoline machine or wasting fuel through constantly using the motor. They point out the fact that the company has very widely increased the area from which its patronage is drawn, and believe that the radius limit may be increased as the necessities of the service demand.

Three of the Four Autocars Operated by L. Dimond & Sons Co., Inc., in Suburban Delivery, Covering a Radius of Approximately 15 Miles from Providence.

The company has just begun the demolition of buildings in Pine street, where a seven-story structure is to be erected with frontage of 133 feet. This will have a court, in the centre, in which the wagons can be loaded, practically the entire equipment at one time, and the machines can be driven in from Pine street and out on to Eddy street. This building will have a combination gasoline and electric garage on the ground floor, as well as the shipping department, while the packing rooms will be on the second floor. The remainder of the building will be devoted to storage and to a furniture workshop, the shop to be on the second floor. This building will be a model and it is expected that the shipping department will be the equal, if not the superior, of any in the country, especially with reference to handling the goods and load-

ing the wagons. The drivers will be off the street, where there can be no interference from traffic, where they can work protected from the storms, and where the goods cannot be damaged by rain.

This shipping department will be sufficiently large to provide for future increase of business, and it will be fitted with the finest equipment that can be obtained. This will make practical the realization of the fullest economy of the machines, for there will be no reason for the delays that are now resultant from sidewalk loading and from shipping room congestion. The garage incorporated with the building will eliminate all delays that are now experienced in the event of a change of machines being necessary, and it is purposed to have facilities that will be ample for at least doubling the number of machines. The management says that the motor vehicles are the logical delivery equipment for the Outlet store, and while they have not as yet a compilation of figures that will actually represent the cost of delivery by the machines, the expansion of the business has been successfully brought about, which is in itself a very large progression. The exact cost per year is being worked out, but the combination service has made this work complex. The cost of tires, however, has been determined to be a slight fraction more than three-quarters of a cent a mile for each machine, which is regarded as being very low.

The Loading Gallery and Chutes of the Providence Public Market in Snow Street, the Baskets Descending from the Second Story to the Wagons by Gravity.

The company has a superintendent of the delivery equipment, and he is expected to have the machines ready for use and to meet every exigency that may arise where they are in use. He dispatches the machines in the morning from the service station and he sees them all reach the garage at night. He attends to all mechanical needs and supervises all repairs and adjustments. He is responsible for the condition of the equipment. From time to time he drives about in a car and observes the manner in which the drivers handle their wagons, and this insures against abuse and carelessness. During the summer season the machines are each withdrawn from service and overhauled and painted, so that by Labor Day of each year the equipment is ready for a long period of hard work. Incidentally the company places high value on the advertising qualities of the equipment and the wagons are very well kept. The delivery of the company will range from 2500 to 7000 packages a day, according to the season of the year, exclusive of furniture and the larger and bulkier house furnishings, and some drivers will sometimes deliver as high as 300 packages a day. The regular deliveries are at 8:30, 1 and 4 o'clock each day but Fridays and Saturdays. But one delivery is made Fridays during July and August, and Saturdays the hours are 9, 2 and 5:30. Under ordinary circumstances the drivers are at the garage by 7 in the evening save Saturday, when 8 to 8:30 is an approximate average. Each driver has a helper, and these are active boys who can cover ground quickly and do a great deal of the "shacking," the driver usually delivering close to the machines.

Shepard Company's Service.

The Shepard Company, which has a very large department store in Providence, is controlled by John Shepard, Jr., who is also the treasurer and executive of the Shepard, Norwell Company of Boston, Mass. This concern occupies a building that is surrounded by Westminster, Union, Washington and Clemence streets, and while the greater part of the ground floor is given over to dry goods, men's wear, and a number of the sections of such stores, no inconsiderable part of the Washington street end is given over to departments for dairy products, groceries and fruit, and in the basement is a large market.

The Shepard Company is the pioneer of the country and perhaps of the world in the use of power wagons for delivery. In the winter of 1894-5 Mr. Shepard had an express wagon fitted with a steam power plant, and proposed to use it for delivery purposes. In experiments it was found impracticable because the wagon would not endure under the heavy stresses, and good traction could not be obtained with narrow steel tires on wet or muddy streets. The following winter Mr. Shepard had a gasoline engine designed for a specially built chassis. Both equipments were constructed by the George Cruickshank Engine Company, Providence, R. I., from designs by L. F. N. Baldwin, who was later widely known as a racing driver of steam cars. This wagon was fitted with a body in-

tended for carrying furniture that was built in the West, which had capacity for 20 bedsteads. This wagon had steel tires and there was difficulty in obtaining traction if the streets were wet or muddy. The engine had 20 horsepower and was a two-cylinder double-impulse motor with hot tube ignition, and the drive was by chain and by belt. The drive from the jackshaft to the rear wheels was by chain of the link and clamp type then used extensively for agricultural machinery, but the chain would not endure under stresses. This machine was fitted with a car fender. It was exhibited extensively during 1896, but it was not practical because of the reasons stated.

Later on Mr. Shepard experimented with both gasoline and electric wagons very extensively. The electric machines were not well built and one of the first was weighted with an extremely heavy body, so that its mileage was comparatively small. As a matter of fact none of the vehicles tried, and they were worked for considerable periods, gave such results as would justify abandoning horses, but it is fair to assume that had they been carefully and systematically operated they might have been more satisfactory. At that time the chief value was in advertising.

The market and grocery when opened required a different character of delivery than the remainder of the store, for food is usually purchased when desired, and it was necessary to increase the equipment materially. Up to December, 1911, when the first of the motor wagons now in use was purchased, from 38 to 42 animal wagons were in service, and from that time up to the end of the following February, six Autocars were purchased. These were utilized for suburban work. From August to December, 1912, 10 2000-pound and four 3000-pound G. M. C. wagons were delivered, this giving the company in all 20 machines.

The intention was when the machines had been delivered to dispense with practically all the animals, but this was not done and the greater part of the G. M. C. machines were withdrawn and the present equipment of the company consists of six Autocars, two G. M. C. wagons, a 5000-pound Lansden electric truck, and a Detroit 1000-pound electric wagon has been ordered, and a 1000-pound M & P electric wagon is now being demonstrated. Besides these the company is using from 22 to 25 horse wagons. The company handles from 3000 to 3500 baskets daily from the market, there being an average of about 20,000 a week, and the number of parcels will be approximately the same, although the largest number ever handled by the store in a single day, during a January sale, is said to have

Providence Public Market's 3000-Pound Kelly Wagon Loaded for a Daily Trip Covering the East Shore from Providence to the Northern Bristol Line.

reached 16,000. The total number of deliveries will approximate 2,000,000 annually.

The company makes delivery within a radius of approximately 15 miles of the store, exclusive of furniture, which is delivered long distances at times. The policy is within a five-mile radius to deliver groceries four times daily, parcels three times and furniture twice; within 10 miles parcels and groceries twice daily, and up to 15 miles parcels and groceries once daily. By reference to the tabulations it will be seen that this includes either side of Narragansett bay to Bristol and East Greenwich, the Pawtuxet and Blackstone valleys and the Attleboros.

The long distance deliveries leave each morning at 10 o'clock. Within the 10-mile radius the deliveries are made at 9:30 and 2:30, but the afternoon trip is made an hour later Saturdays. Within the five-mile radius the groceries are delivered at 7:30, 10:30, 1:30 and 4, with an additional trip at 6:30 Saturdays. The parcels are sent out at 10:30, 1:30 and 4, and an extra trip at 6:30 Saturdays. There is no change in this schedule throughout the year save on Fridays during July and August, when the store is closed at noon and the first afternoon trip is made at 1 o'clock and the second is omitted.

The machines and wagons that make one and two trips during the day are loaded with both parcels and groceries, but those that make three and four trips each are loaded with either parcels or groceries, there never being combination loads save in the event of emergency. The furniture deliveries are not made to schedule, the wagons being sent away as the goods are ready for shipment, but the intention is to start them as early as is practicable.

The motor wagons are generally used on the routes in the suburbs, but the Lansden electric truck is utilized for freight haulage from the railroad and shipping terminals, and to and from the warehouses. The electric machines now having demonstration are used for city delivery, and the gasoline wagons are used on the

West and East Shore routes, the Blackstone valley, the Pawtuxet valley and the Attleboro routes. The machines carry combination loads, the parcels being separated by wire gratings, and each wagon is fitted with an ice box for use in summer, in which are carried the meats, butter, cream and similarly perishable packages. The drivers of these routes take orders as well as make delivery, and the start is made at 10 daily to allow time for making up the packages from the slips turned in by the drivers when they arrive. Saturdays the loads are usually very large and it is necessary to have two ice boxes to preserve the orders that might be damaged by the heat in transit.

While the suburban routes have unusually heavy delivery throughout the summer months, the work is such that there is no change made in them at other seasons and the same areas are covered throughout the year. But with the lessening of the work for the suburban wagons in autumn the city delivery increases. But there is annually a general increase in the business carried on in the city and its suburbs.

The West Shore Machine, a 3.5-Ton Frayer-Miller (Kelly) Truck, Loaded with 401 Baskets for the Providence Public Market's Distributing Station at East Greenwich.

The traffic is very heavy in Westminster and Washington streets, and no vehicles are permitted to stand in the former, it being a one-way thoroughfare during the business hours of the day. Traffic can move through Union street toward Washington and through Clemence street in the same direction. Washington street is two-way, and for this reason is generally filled with traffic. The loading at this store is done in Washington and Clemence streets, and in the latter it is necessary to keep one line of wagons only, for the roadway must be free for the passage of fire apparatus in the event of need. As the roadway is not more than 15 feet, and the sidewalks are just wide enough for a single pedestrian, it will be seen that loading in Clemence street is accomplished under difficulties at all times. In this street the parcel wagons are generally loaded, but the grocery and the combination wagons are "stacked" in Washington street.

All the packages from the market are brought to the street floor on elevators and taken to the sidewalk, where they are sorted and packed in the wagons, and the parcels are similarly brought to the Clemence street sidewalk by an elevator and brought to Washington street and sorted and packed. Clemence street extends from Washington street to Fountain street, and into this the wagons of the company are drawn while waiting, for nine or 10 are practically all that can be handled in the street beside the store, and six wagons and machines is about the limit for the Washington street end of the building. Besides, the furniture must be loaded from the Clemence street side. There are two elevators for the grocery and market, two for the furniture, and one each for the parcels and dry goods. Because of the narrow walks in Clemence street the wagons must be a sufficient distance apart so the carriers can be placed in the roadway behind them, and because Washington street is so much travelled the carriers are seldom used, the packages being brought to the wagons in the arms of the drivers and helpers.

The loading at this store is accomplished under conditions that necessarily require a great deal of time, and there appears to be no practical way of making any change for the better because of the practically prohibitive price of land and the great cost of a sufficient area to establish a loading station on private property. The Autocars are kept at the service station of the Autocar Company and the other machines are kept at the garage of the Shepard Company, which is close to the stable, both garage and stable being under the supervision of the superintendent of the shipping, Robert Gibbons. Each driver has a helper, it being the custom of the company to develop the drivers from the helpers, and the men report at the store from 7:30 to 9 in the morning. The expectation is to finish the last trips for the day by 7 o'clock at night, but often the suburban drivers finish later during the summer months. The company will send special deliveries when required, the last of these being sent away when the store closes for the night. Under some circumstances some of the wagons are loaded when they return from the last trip and are sent to the garage, the start being made early in the morning, this plan gaining a couple of hours that might otherwise be lost in loading in the morning.

The experience of this store is that with the machines the deliveries can be more quickly made in the suburban sections, and a greater degree of satisfaction gained for the customers. The area covered with the machines is not greater than with animals, but it is served more expeditiously and, in all probability, more economically. The intention of the company is to use

the gasoline machines for its suburban work and if the electric wagons are proven economical in practise they will be used on the routes closer to the store, and possibly on some of the main city work.

The Dimond Store Service.

The store of L. Dimond & Sons Co., Inc., is in three buildings, the first between Westminster and Middle streets, with Union street at one side, the second between Middle and Weybosset streets, and the third between Middle and Weybosset, with Eddy street at one side. The first and second buildings are connected by a subway and by foot passages over Middle street from the second, third, fourth and fifth floors. This concern handles all kinds of dry goods, house furnishings and groceries, dairy and general food products. It is the smallest of the large department stores of Providence and it sends out an average of 35,000 parcels a month, exclusive of the deliveries from the grocery and market departments. The company has in the service of the stores four Autocars and 12 wagons, and five wagons are utilized for the food delivery.

The policy of this company is to use its motor wagons in its suburban work, and to deliver in the city with the wagons. This plan has made it possible to eliminate the use of about a dozen express services that were formerly used, to serve its customers to much better advantage, and to do away with all complications arising from the indifference of the employees of other concerns. Not only this, there is a good deal of economy in this service, for the price paid per package was very large as compared with the cost of those delivered by equipment owned by the store.

The shipping room of the store is in the basement of the second building and the packages are brought to it from the departments by elevators, and are taken through the subway from the first building. There is a single elevator from the shipping room to the sidewalk in Middle street, and here all the parcels and furniture are loaded. The loading for the market and grocery is done in Eddy street. Traffic in Eddy street during business hours is from Westminster street to Weybosset, in Union street from Weybosset to Westminister and access to Middle street is through Union from Weybosset, a two-way street. The Dimond wagons and machines enter Middle street from Union and after loading are driven out through Eddy street. Middle street is about 15 feet wide, with 30-inch sidewalks, and as the store controls the greater part of the property at either side it is permitted to use it with practically no limitations. There is an entrance to the store at either side directly under the galleries by which the two buildings are connected.

Because of the need of the customers having access to the two buildings on the ground floor it is not practical to use all of the street, and the space available, after the requirements for carriers and handling have been provided for, will suffice for 10 vehicles. So it will be seen that it is not possible to load more than half the equipment at a time. The average delivery wagon will hold about 1000 pounds of the general run of goods and packages, but the bodies of the motor wagons will take approximately three times as much, so that in putting on a full load more time is required.

The Dimond Company has made no change in its city delivery with the use of motor wagons, for it now uses the same number it has for a considerable length of time, but the addition of the four machines has made it possible to better serve its customers and over the same area that is covered by the delivery service of the other two stores. One Autocar is sent over the East Shore route daily as far south as Bristol, another

Loading the Motor and Horse Wagons for the R. L. Rose Company, the Animal Vehicles for the City Delivery and the Machines for the Suburbs.

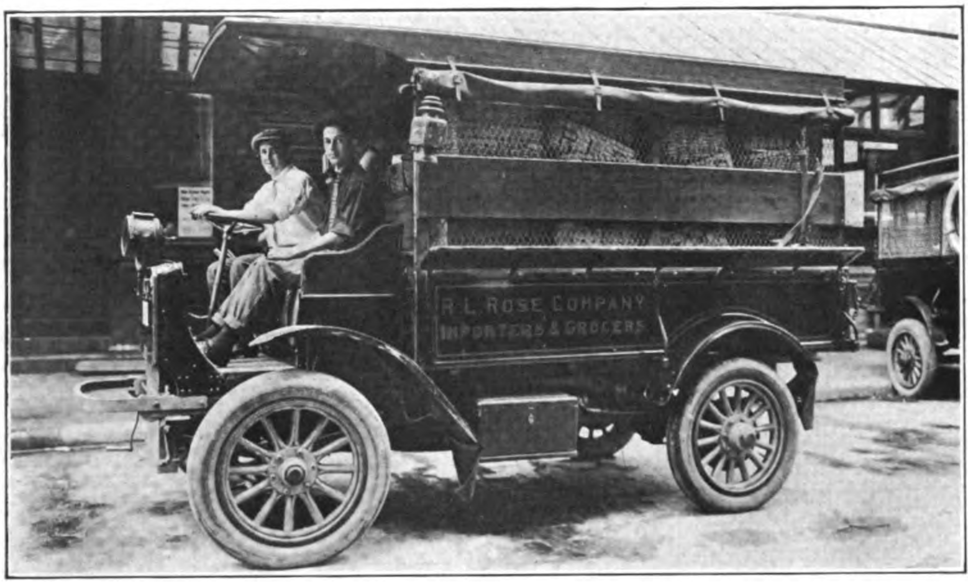
is sent over the West Shore route daily, covering all of the localities between Providence and East Greenwich, and a third goes to the Pawtuxet valley three times a week and to the Attleboros every alternate day. The fourth is sent west to Centerdale and vicinity daily, and in addition is used in the delivery of furniture.

Three deliveries are made daily, at 8, 1 and 4 o'clock, save Friday during July and August, when the second afternoon trip is omitted. The Saturday morning delivery is made at 9 when the store is closed Friday afternoon. The wagons have a driver and a helper as a crew. The machines are kept at the service station of the Autocar Company and the wagons at the company's stable. While the company has the use of Middle street by sufferance and there is no reason to believe that this use cannot continue, there is a great deal of time required for the loading, and there is no possibility of eliminating this waste. It might be practical to provide more elevators, but the packages

must be carried along the street to the wagons, sorted and arranged for delivery, and there would be no appreciable gain in the time necessary for making ready for the start. Assumedly, the drivers work conscientiously on the routes and so the only chance for gain would seemingly be in handling at the store.

Providence Public Market Delivery.

What is regarded as the largest business enterprise of the kind in America, and perhaps in the world, is the Providence Public Market, which occupies a large building surrounded by Westminster, Snow and Chapel streets and a driveway from Chapel to Westminster street. This concern has three other large stores in Providence and a branch at Worcester, Mass., that is about two-thirds as large as the main store at Providence. Besides dealing in groceries, meats, dairy products, vegetables, fruits, fish and staple and special food, it has its own bakery in the same building. The concern is credited with doing upwards of a $6,000,000 business annually, and it is noted that the patronage has increased consistently each year.



The "West Shore" Motor Wagon of the R. L. Rose Company, Starting with Its Morning Load for the North Section of the Route.

This concern has the largest delivery service connected with its main store in Providence of any concern in New England, it using regularly 70 single wagons and 10 additional wagons Saturdays, as well as a three-ton Frayer-Miller truck and two 3000-pound Kelly machines, and several two-horse teams and trucks. The delivery of this concern is within a smaller radius than is covered by the department stores, extending to the Pawtucket line on the north, through East Providence, Barrington and Warren to Bristol, south for about 10 miles along the West Shore, and west about six miles. In the city four deliveries are made daily, at 7, 9:30, 1 and 4 o'clock, but where there are two deliveries daily these are at 7 in the morning and 1 in the afternoon. The company has from 135 to 140 horses in use constantly.

Three years ago the company purchased its first machine, the Frayer-Miller truck, and this was for use primarily in transfer service. The company had a distributing station at Shawomet Beach, where horses and four wagons were kept, and the goods for delivery in this section were hauled over the road early each morning and were delivered at the station, where the baskets, already made up, were transferred to the single horse wagons and carried out. This service was found to be a material saving, but it was believed that there was economy in a motor truck. This work was constant throughout the year, but during the summer months the loads were often more than could be sent with one vehicle. The company has a contract with a man who superintends the delivery from Shawomet and two of the drivers live there, the other two living at Providence.

The truck was used for this transfer, loading at the store at 2 in the morning, and making the drive of about 11 miles, arriving at 5:30 to 6. From this point the delivery was begun at 7 o'clock. As much of the load as could be taken was placed in the wagons and the remainder left at the station and the truck returned to Providence. The remainder of the day it was used for hauling freight from the railroad and shipping terminals and the warehouses. With the increase of business during the summer it was often necessary to send a wagon with a load as well, for it was found that when the machine was filled and all the baskets packed on it that could be carried much time was lost in loading and handling.

In the delivery from Shawomet all the wagons are provided with ice boxes for the packages of perishable goods, for the routes are long and the time required for covering them necessitates care in handling. The drivers take orders on these routes, and these are sent to the store and delivered by the drivers, so they are ready for sending out in the morning. As these orders are made up during the afternoon and early evening they are kept in refrigerating rooms until loaded in the morning. In the hot weather rapidity in handling between the store and the distributing station is a factor of some importance. Previous to this year the Frayer-Miller truck was the only machine in service, the other routes being served by horse wagons, but this spring two Kelly 3000-pound wagons were added to the equipment, and one of these is used to serve the customers in the lower section of East Providence, reaching Riverside, Narragansett Terrace, Drownville, Barrington, Nayatt, Hampden Meadows, Warren and South Warren in the morning, and going as far as Riverside in the afternoon.

The other Kelly machine is used to make deliveries in Edgewood, Pawtuxet, Pawtuxet Neck, Dryden Heights, Spring Green and Lakewood. The East

Providence route is known as the East Shore, and the Edgewood-Lakewood route as the West Shore, the former going outward about 12 miles and covering approximately 50 miles daily, while the West Shore route will, for the two trips, reach 40 miles or better. Instead of sending horse wagons to Shawomet with the baskets the larger truck cannot carry, the West Shore machine very often makes an early morning trip and then is driven back to cover its regular work.

There is one delivery a day from Shawomet, each wagon covering two routes; there are two deliveries daily to Riverside and one delivery south of that for the East Shore route; two deliveries daily for the West Shore route; two deliveries daily to Auburn; one delivery daily to Norwood, Centerdale and Rumford; three deliveries a week to Oaklawn and once a week to Hillsgrove and to Seekonk.

For the transfer work and the suburban routes the machines have thus far given satisfaction, and it is believed that there will be even better results with longer experience, but the members of the company are as yet of the opinion that motor equipment is not practical for city delivery. The company does not deliver from any of the branch stores in Providence, and it is estimated that about half of the purchases are taken away by the customers. But with this reduction about 30,000 baskets are taken out each week, of which about 7000 are delivered Fridays and about 9000 Saturdays.

Handling the baskets is done with speed and care. All the packages are sent by belt conveyors from the different sales departments on the first floor to the shipping room on the second floor. Here they are sorted for number and are then distributed into numbered trays, conveyors carrying some of them to different parts of the room. From the trays they are checked into the baskets, and if there is to be a wait of such a length that the goods might be affected the baskets are placed in refrigerating rooms until the drivers report. There are seven inclined chutes from the shipping room and the wagons are backed under these and the baskets sent down in very quick time, the drivers arranging them as they receive them. There are two entrances that can also be utilized for loading or receiving. When the wagons return the empty baskets are sent to the shipping room by a conveyor. The fact that 80 wagons can be loaded four times daily in a street with a 15-foot roadway and a three-foot sidewalk, and a 10-foot alley, without congestion or confusion, shows that the delivery has been splendidly systematized. The chutes descend from galleries on the side of the building, and permanent canopies protect the wagons during the loading. Most of the newer wagons have tops, but the older ones are open.

R. L. Rose Company's Delivery.

The R. L. Rose Company is the largest high-class grocer in Rhode Island, having its main store in a building extending from Weybosset to Pine street, with Hay street at one side of the structure, a branch store in Westminster street, and another in Pawtucket. The company does its principal volume of business from the main store and only delivers from this, but there is a separate delivery equipment for the Pawtucket store. The company's business from the main store may be said to extend from the Pawtucket line south to Bristol and Fall River on the east side of Narragansett bay, and to Westerly on the west side. In the delivery in and about Providence 15 single horse wagons and three Autocars are used.

During the summer when the business is somewhat lighter in the city one of the Autocars makes daily trips to Narragansett Pier, a distance of 33 miles, making delivery south of East Greenwich, but taking the bulk of its load to the pier. Often more than the machine can carry is to be sent out, and this is shipped by electric express and is delivered by the motor wagon before it returns.

One Autocar is used on the West Shore route, this delivering as far south as Shawomet, Warwick Neck, Oakland Beach and the different localities in that section each day, and going to Apponaug and East Greenwich Saturdays. The third machine covers the East Shore as far south as Nayatt and Warren, making this trip in the afternoon and delivering in the Smith hill and Mount Pleasant sections of the city during the morning.

This is the summer arrangement for the machines, and during this time the work in the city is generally at its lowest ebb. The deliveries by horse wagon in the city vary from one to five, according to the locality, but there are usually 15 wagons busy, the horses being worked a half day each and making an average of about 15 miles a day. During the remainder of the year one Autocar is used in making three trips daily, covering South Providence, Edgewood, Pawtuxet and Lakewood, some portions of this section being reached twice. Generally another machine is worked with this one late in the afternoon. A second machine has a route that is as far west as Graystone and Centerdale, and this covers East Providence on a second trip. The third machine covers the north section of the East Side of Providence, Smith hill, Mount Pleasant, Johnston and Auburn, practically reaching the outskirts of the city, and this is also worked to help serve the Lakewood machine.

The work of the motor wagons has been very satisfactory in all suburban service, for they are driven from 50 to 60 miles a day, and with them it is possible to give the customers attention that would not be practical without a considerable number of animals and wagons. Not only this, but there is a decided saving in the Narragansett Pier delivery, which was formerly sent by electric express and taken out by wagons. This machine is driven from 80 to 95 miles each day. So economical has this service been found that this summer the company seriously considered sending loads to Watch Hill, which would require a drive of from 125 to 140 miles a day, but this was abandoned for a time. Now the goods are sent to Westerly by railroad and taken to Watch Hill by wagon.

The company is not yet convinced that it would be economical to use motor wagons for city delivery, but it is probable that there will be careful experiment made to determine the relative costs of motor and animal service.

GOODYEAR SERVICE STATIONS.

Tire Maker Establishes Chain of Plants to Economize Time for Truck Owners.

The Goodyear Tire & Rubber Company, Akron, O., has established truck service stations in a number of the large cities of the country, and these will be added to from time to time as conditions justify. These include garages and wheel shops that are open day and night with complements of expert wheelwrights and mechanics to meet any requirement and with facilities to perform any work that may be needed. The stockrooms are supplied with everything necessary for wheel repair and tire repair or exchange, such as wheels, rim bands, bolts, fastenings for every type of truck, and material that may be worked. The purpose of the night force of men is that the owner may place his machine in the garage at night and have it ready for use the following morning. This policy was adopted because serious interruption of service was entailed by tire renewals, especially where the work was necessarily sent to another city.

The Wood-Working Machines Used in the Wheel Shops of the Goodyear Service Stations for Fitting Wheels for Tire Installations.

It has been experienced that repair of tires, changes of wheels and exchanges of shoes frequently require considerable time unless in the hands of those who specialize in such work, this necessitating the withdrawal of the machines to the great inconvenience of business men. With a view of insuring the greatest utility of machines where tire or wheel attention is necessary and to bring about the greatest measure of economy the stations were decided on. In addition to special attention to wheels and tires the stations will undertake any other necessary work with the assurance it will be done properly and reasonably.

TRUCKS TRANSPORT RACE HORSES.

Plan Eliminates Disadvantages Attendant Upon Shipment of Animals by Railroad.

A new use was found for the motor truck when 50 trotting horses that had been racing at the Parkway Driving Club's summer meeting at Gravesend track, Brooklyn, N. Y., were loaded into padded moving vans, together with all their sulkies, clothing, boots and racing paraphernalia, and taken to the driving park in Hohokus, N. J., where the second meeting of the Metropolitan circuit was scheduled. An automobile had been used all the week in place of horses to harrow, float and brush the track for the trotters at Parkway, and when the motor vans backed up to the stable doors and took the horses on board for a quick trip to Hohokus, old time horse followers were compelled to confess that the motor machines were good for something after all.

High express rates for the transportation of race horses caused the resort to automobiles. W. H. Strang, a member of the driving club, owns a fleet of them and conceived the idea of taking the trotters from the Gravesend track to the New Jersey course. One of the advantages of the motor vans, which the horsemen appreciated, was the direct run from barn to barn. Under the old way of shipping it was necessary to hire trucks to take the animals from the race track to the railroad station and then from the station to which they were sent to the race track at that point, this involving double loading and unloading, and double charges for cartage, which the motor truck eliminated altogether. The transportation of race horses in vans is getting back to first principles. One hundred years ago, and until railroads were built, thoroughbred runners were commonly transported in horse-drawn vans in England.

One of the largest taxicab sales recorded by the White Company, Cleveland, O., in recent years, was the contract signed with the Taxicab Company of California, for 63 White machines. The purchase was a result of the service given by a fleet of 19 White taxicabs for 20 months in San Francisco, during which they were subjected to the hardest kind of treatment in a city unrivalled for the severity of taxicab operation. With the added equipment the Taxicab Company will have a completely standardized installation of 82 White machines. In addition to buying cabs, the company placed an order for five White six-cylinder, 60 horsepower, seven-passenger touring cars.

ENGLAND'S FIRST EXCLUSIVE TRUCK SHOW.

America Unrepresented Among 65 Exhibitors at Olympia---Steam Vehicles in Second Place ---Notable Lack of Electrics---Some Interesting Constructional Details Revealed.

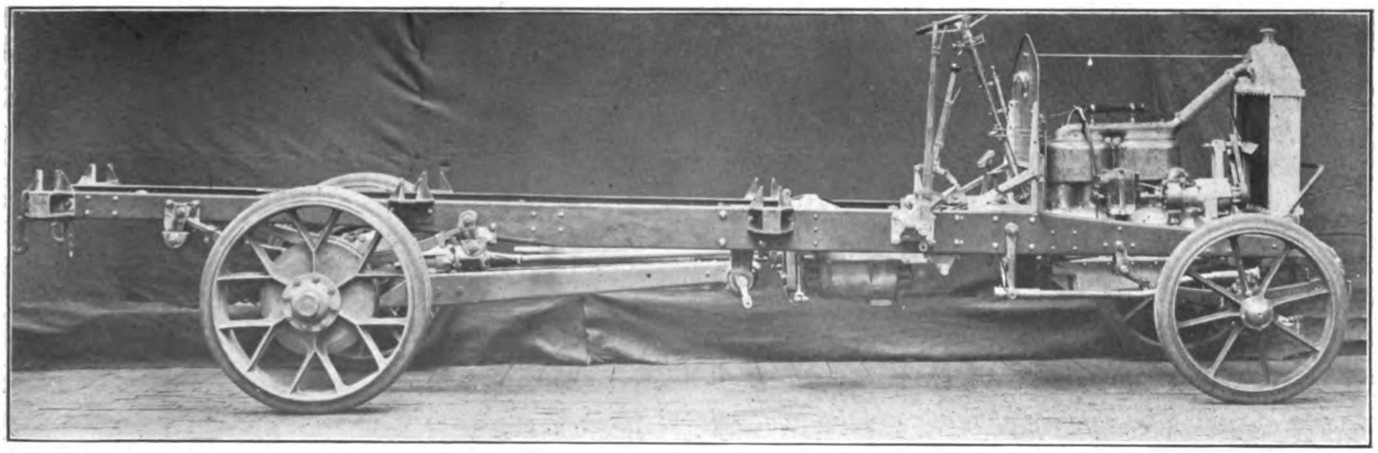
Special London Correspondence.

ALTHOUGH America has been holding commercial motor vehicle shows in New York and Chicago since 1911, and in Boston and some of the other large centres since 1912, London, England, has just experienced its first exclusive display of this character at Olympia. Four years ago, an attempt was made to hold an exhibition of self-propelled vehicles for industrial purposes, but the result was a showing mainly composed of omnibuses and cabs. Even then the list of exhibitors was so small that motor boats and marine engines were added in order to make a creditable display.

The show which opened in Olympia, July 18, was decidedly representative of the industry in Great Britain, although American manufacturers appear to have been somewhat conspicuous by their absence. Four countries, outside of England and Scotland, were included among the makers, these being France, Germany, Italy and Belgium. Of the 65 exhibitors, 53 displayed gasoline vehicles only, nine steam, two both gasoline and steam, and one gasoline-electric. Aside from the chassis and complete machines designed for strictly haulage purposes, there were a large number of char-a-bancs, taxicabs and fire and municipal service vehicles. A particular feature of the exhibit was the number of light delivery vans, although the heavy duty wagons and trucks were very much in evidence.

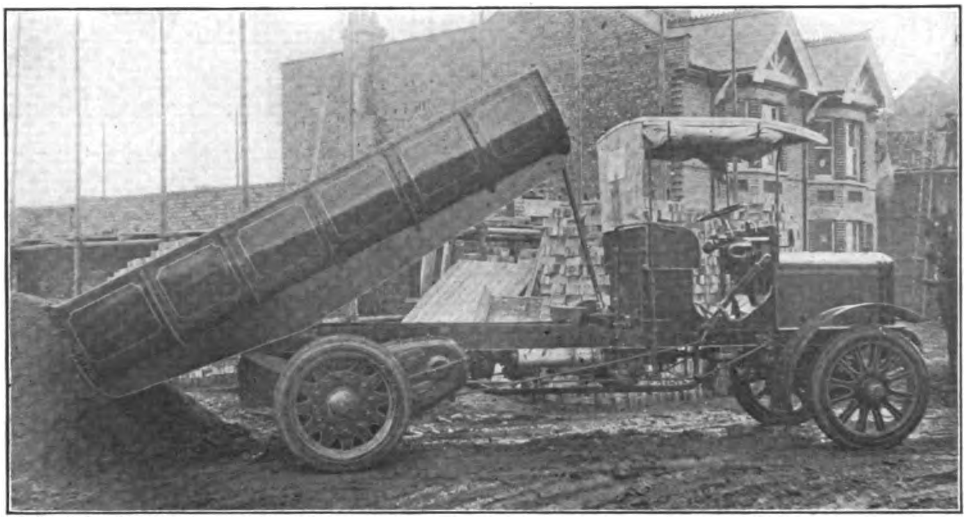
From an American viewpoint, it is perhaps strange to note the percentage of steam vehicles, and the almost total lack of electrics, except for the single Tilling-Stevens gasoline-electric. The former type of vehicle has met with ready acceptance in Great Britain, as well as on the Continent. For the most part they are designed to carry heavy loads. The Clayton & Shuttleworth, Foden, Garrett and Wallis were presented in three-ton models; the Allchin, Aveling, Foden, Garrett, Tasker and S. M. in five-ton; the Exshaw, Leyland and Yorkshire in six-ton, and the Wallis in eight-ton models. The Clayton & Shuttleworth also is produced in five and seven tons capacities. All are adaptable for use with trailers. The Aveling and Leyland makers produce gasoline machines as well.

The gasoline machines on display included: Adler, Albion, Alldays, Argylls, Austin, Autocarrier, Aveling, Bayard, Belsize, Benz, Berliet, Berna, Brazier, Buessing, Charron, Churchill, Commercar, D. A. A. G., Daimler, De Dion-Bouton, Delahaye, Dennis, Economist, Fiat, Girling, Globe, Hallford, Halley, Hillman, Karrier, Laycock-Goodchild, Licorne, Leyland, Mass, Maudslay, McCurd, Milnes-Daimler, Minerva, N. A. G., Napier, Pagefield, Pedrail, Phanomobile, Renault, Salmon, Scout, Standard, Star, Stoneleigh, Straker-Squire, Thornycroft, Tilling, Unic, Vinot, Wolseley.



Wolseley 3.5-Ton Chassis, Designed to Conform with the Subsidy Requirements of the British War Office.

The show was a success in every way. Perhaps it might be held that it had for its chief object the interesting of the business man in the economical advantages to be obtained from the use of the mechanical transport. As an example of the methods employed to demonstrate this feature mention may be made of the object lesson presented by the attendants at the Hallford stand. The existing rail rate between London and Birmingham varies from $4.50 to $11.25 a ton, according to the class of goods carried, but for some time, one of the Hallfords shown has been hauling all classes of goods between these two points at a rate of $3 a ton. Such arguments are not exactly new to British business men, but there is little doubt that this exhibition gave abundant opportunity to bring these facts more directly to the attention of men who were investigating the situation.



Commercar Six-Ton Tipping Wagon with Telescopic Worm Gear Hoist, Driven Through Special Clutch.

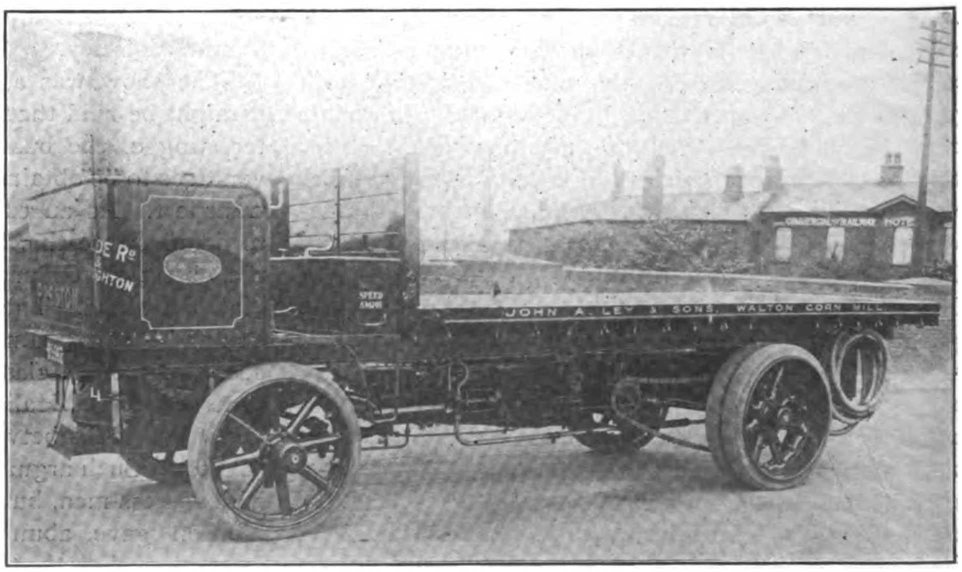
A visit to the various stands could not help but indicate that the specifications set forth in the conditions under which motor truck owners may receive the war office subsidy has had its effect upon chassis design. A series of trials is to be held by the war office in October, and it would appear that many British makers are striving to conform to the requirements in order that British purchasers of commercial wagons who wish to have their vehicles subsidized by an annual donation from the government may be in a position to secure a machine suitable for their needs and at the same time available for bonus and employment by the authorities in time of war.

The Leyland six-ton chassis shown herewith may be taken as an example of the steam vehicle construction which has proved successful in Great Britain. This particular chassis was designed for J. A. Ley & Co., of Preston, England, a firm which purchased its first Leyland steamer in 1903. That machine is still doing useful work six days a week. The latest model, like the older type, has a vertical fire tube boiler and an underslung engine, although there is a notable difference in the utilization of mushroom valves instead of those of the sliding type, which is held to make for the use of steam of a higher temperature and therefore for greater economy in running. A two-speed transmission and side chains deliver the power to the rear axle.

Several of the steam wagons were shown with tipping bodies. Both the Exshaw and Yorkshire designs are mechanically operated, the former utilizing a hydraulic jack worked by a small steam pump, the arrangement being such that the load may be dumped either to the right or the left as desired. The Yorkshire device may be operated either by hand or mechanically, the latter being accomplished by means of a clutch on the flywheel. When placed in action the body travels backward into such position that it does not actually begin to tip until the point of support is over the back of the frame. The Exshaw also is fitted with a winding drum on the differential shaft, operated by the steam engine, this being utilized for loading and unloading or when it is desired to employ the power as a stationary engine.

The automatic coupling for trailers on the Allchin model also is of interest, this being self-locking in action and designed to prevent accident to the man attaching the drawbar. The driver sets a trigger arrangement, so that immediately the end of the drawbar enters the mouth of the bracket, it is guided to a central loose piece which, when pressed like the trigger of a gun, releases the drawbar pin and drops it into position, thereby locking the assembly. The Allchin also employs a trailer brake, which may be operated by the driver by depressing a pedal from the seat. A similar arrangement appears on the Leyland, as well.

Considering the gasoline vehicles: Special attention was drawn to the Austin stand, where the new 2.5-ton chassis was shown for the first time. The particular feature of this machine is the method of transmission from the differential shaft through two angularly disposed cardan shafts and bevel gearing to each of the rear wheels. It is maintained by the maker that the necessity for torque and thrust rods has been eliminated by the special arrangement of double springing, which is a combination of the underslung and overslung types. The chassis is built for work

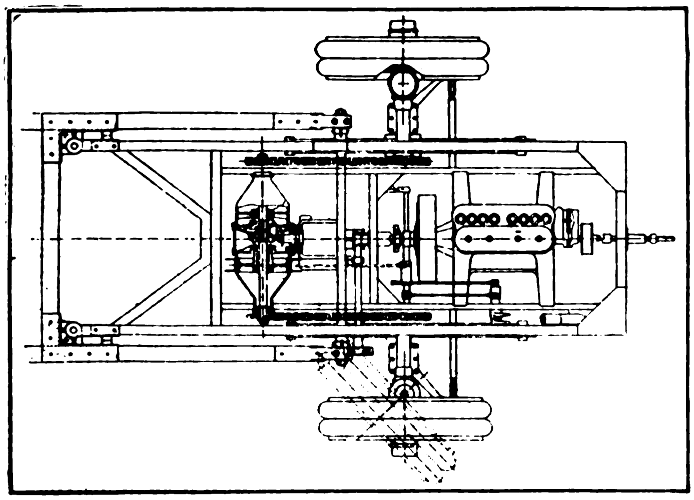


Leyland Six-Ton Steam Truck, an Example of This Type of Vehicle Which Has Given Excellent Satisfaction.

in any country and on all kinds of roads, and may be fitted with tipping gear and winding drum. Other exhibits at this stand were a 15 horsepower delivery van supplied to the postal authorities at Pernambuco, Brazil, and an ambulance fitted to the same chassis.

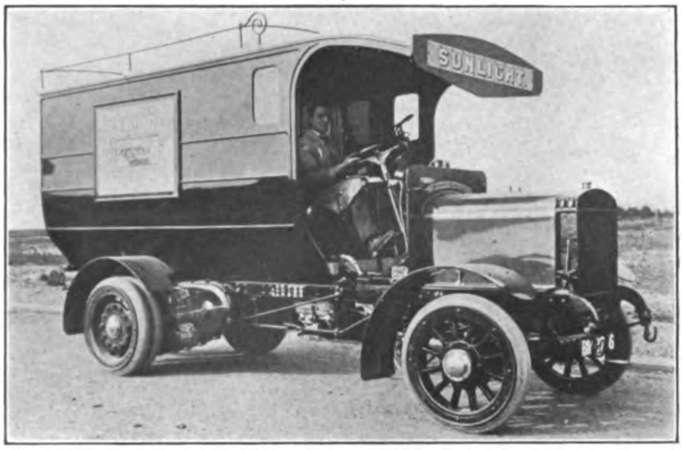
The Aveling three-ton gasoline wagon is of recent introduction, the firm being known chiefly as a builder of steam vehicles. It has a four-cylinder engine, cone clutch and four-speed gearbox. Drive is by shaft to a worm driven rear axle, the casing for which consists of massive steel castings. The rotative effect is resisted by a cast steel triangular torque member, while the top leaves of the rear bearing springs are left to take care of the tractive effort. A feature of the design is that of carrying and anchoring the blocks for the foot brake gear. These are secured to a bridge piece, each of the blocks being anchored to a crosshead, which is free to slide vertically.

In view of the interest taken in subsidized models, the German Buessing, which is the only machine subsidized by Hungary, and which is also approved by Austria, Prussia and Bavaria, attracted particular attention. The single model shown was rated at five tons. The four-cylinder motor is of 40 horsepower. The clutch is a cone. The power is taken by means of a long propeller shaft to a combined gearbox and differential, which makes provision for four forward speeds and reverse. The final drive is by big side chains. The suspension is of special interest. The front springs are aided by additional coil springs both fore and aft, while the rear springs carry the weight on a combined arrangement of rollers and pivots. The spring mounted radius rod is another characteristic of the design. The body shown was divided into two compartments, which may be dumped together, or either separately.



Sketch Showing Details of Mass Front Drive Tractor Construction.

Another example of the mechanically operated tipping body was found at the Commercar stand, this having been sold for service in Toronto, Canada. This is fitted with a telescopic worm gear, which is driven by means of a special clutch through a worm and chain set from an extension in the gearbox. In the main the chassis follows standard Commercar design.

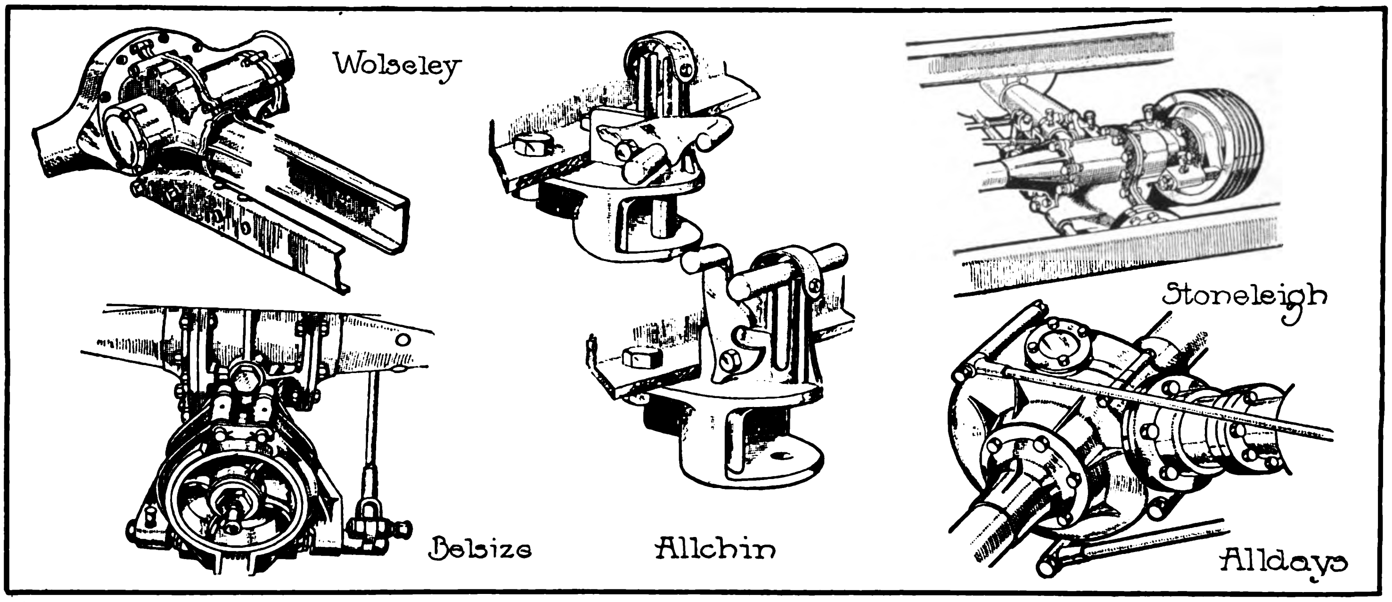


Commercar Four-Ton Box Van, One of a Fleet of 14 Operated by Soap Concern.

The maker also displayed a four-ton box van, one of a fleet of 14 sold to a British soap concern.

Front-drive machines are somewhat new in Great Britain, and for this reason considerable interest centred about the Mass tractor stand. This is made under the so-called Bezancon patents. The motor is of the vertical type, with four cylinders, cast en bloc. Centrally disposed forward of the front axle, the four cylinders run parallel with the frame. The power unit is mounted on a sub-frame, which is of pressed steel, of channel section and wood packed. Power is transmitted through a cone clutch, the speed change and differential gears being enclosed in one casting, located immediately behind the clutch. The differential shafts project outwardly from the frame sides, and the sprockets fitted thereto take the drive, which is transmitted through a light roller chain. Each forward chain wheel is situated over the front axle close to the swivel point. The same shaft has at its outer end a small bevel, which meshes with a second bevel wheel, horizontally disposed at the top of each swivel pin, thus forming a pair of mitre gears. At the bottom end of the pin is fitted a further bevel pinion, which engages with the crown bevel bolted to the hub of each front road wheel. The whole arrangement is more completely brought out in an accompanying sketch.

Austin Delivery Van Supplied to Postal Authorities in Pernambuco, Brasil.



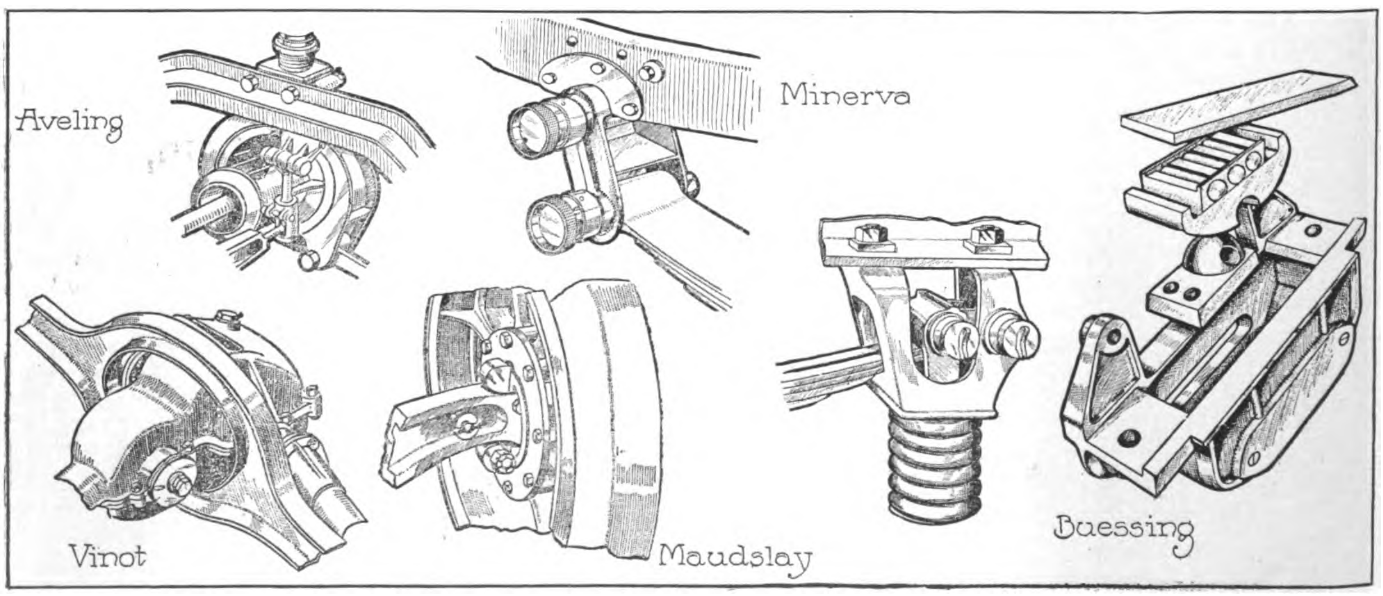
Mechanical Details Revealed at Olympia: Wolseley Bridged Axle and Double-Channel Torque Member, Brake at Back of Belsize Gearbox, Allchin Automatic Coupling Opened and Closed, Air-Cooled Brake Drum on Stoneleigh, and Torque Members on Alldays Differential Gearcase.

Still another new design is the 3.5-ton McCurd. This is said to conform in all its dimensions to the new Scotland Yard regulations for motor 'buses. Accessibility to all parts, and the easy mounting and dismounting of them are its leading features. Three independent sets of brakes are fitted, two of these being side brakes, one operated by the foot and the other by hand, and the third is located on the countershaft. The change speed device is what is termed a reversed gate, this being recessed so that the gate is underneath the rocking centre above it.

One of the features of the Wolseley 3.5-ton chassis, designed to conform with the war office subsidy requirements, is the new type of rear axle, which is of the bridged construction, with the main forging inclined 45 degrees to the vertical. Particular attention is drawn to the combined radius and torque bar.

The Stoneleigh model is produced by the well known maker of Siddeley-Deasy pleasure cars. It is fitted with a 24 horsepower Knight engine, inverted cone clutch and transmission affording three speeds forward and reverse. The rear axle is worm driven, and this and the gearbox are rigidly connected by a stout torque and thrust tube, which encloses the drive shaft. Another feature is the position of the foot brake. The worm shaft is extended backward and mounted thereon is a ribbed brake drum surrounding a pair of expanding shoes.

Space does not permit of mentioning in detail all of the new features presented, and it will be found that some already have been described in these columns. This is particularly true of the D. A. A. G., the Halley Colonial model, the Pedrail and others. The Pedrail attracted unusual attention because of its novelty. In general the principal employed is somewhat like the so-called caterpillar design in America, although it is termed an elephant foot in Great Britain. The ordinary driving wheels are replaced with a series of wheels, over which an endless chain deposits a number of sections of hard rubber upon the ground.



Constructional Features in Olympia Display: Spring Mounted Brake Anchorage on Aveling Gasoline Chassis, Large Spring Links and Their Oilers on Minerva, Pressed Steel Rear Axle on Vinot, Centre Pivot Steering Wheel on Maudslay, and Front and Rear Auxiliary Springs on Buessing.

DELIVERING STRUCTURAL STEEL BY TRUCK.

By George D. Crain, Jr.

GRAINGER & Co., Louisville, Ky., manufacturer of structural steel and iron, has turned from the use of animal vehicles to the motor truck for the delivery of stock within the normal range of motor delivery, making shipments outside of the city by railroad, there being a spur track from a railroad to the works. The company does an extensive local business, there being a foundry in connection with the works, and as it will build anything, from a gate to a building frame, and from a casting weighing a pound to one weighing several tons, it will be understood that the haulage equipment must have capacity to handle it.

The company, prior to using a motor truck, used a truck and a team of two mules, and where the work was of large size had contract with a company specially equipped for heavy transportation. When the change was decided on it was found desirable to have a machine that would serve all requirements, and a vehicle was built by the Transit Motor Car Company. While the machine was rated as two tons capacity it was designed to endure under a considerably heavier load. For instance, the rear axle was made much larger, the wheels and tires were made heavier, and the chassis frame was lengthened so as to take a body adapted for the handling of metal rods and strips. The rear axle is a size usually built into a 3.5-ton truck, and the wheels are fitted with 36 by five-inch band tires forward, and 46 by four-inch dual block at the rear. The motor was fitted with a Pierce governor that is set for a maximum speed of 12 miles an hour. The truck body is low, wide and long, and overhangs the chassis frame at the sides and ends, so that it is possible to load it and have the centre of gravity comparatively low.

The Specially Built Transit Truck Used for Delivery by Grainger & Co., Structural Steel Builder, Louisville, Ky.

Since the truck has been in service a great deal of the haulage that was formerly done by contract has been done by it, and it has been necessary to resort to contract work only when the construction is such that special equipment is required to handle it. Viewed from an experience that was begun last December, the motor truck has made practical a decided saving. For instance, the company has a machine that has at least double the capacity of the mule truck when measured by mileage, and there is a considerable saving because the additional work was paid for at contract prices.

The actual cost of operating the mule team truck included $34 a month for stabling, $4.80 a month for shoeing and $40 a month for the driver, a total of $78.80 without considering depreciation, interest, taxes, maintenance and other expenses. During the eight months previous to December, 1912, the expense for drayage was $411.60, an average of $51.45 a month. Adding this to the expense previously stated for operation the total is $130.25.

When the truck was placed in service care was taken to load it rationally, and for this reason more work was done by the contractors than was found necessary later on. The cost for the driver at $14 a week for three months was $182, and the expense for fuel, oil, supplies, accessories, etc., during the same period was $62.67. Adding to this the charge for haulage of $53.75, the total was $298.42. The monthly average is $99.47, and contrasting this with the total of $130.25, there is a saving of $30.78. This is an average of $1.23 a day, or $369.36 a year. Taking the actual cost of operation, without figuring interest, depreciation, or other charges, the truck cost during the three months $81.55 a month as against $78.80 for the mule team truck, this being a difference of but $2.75.

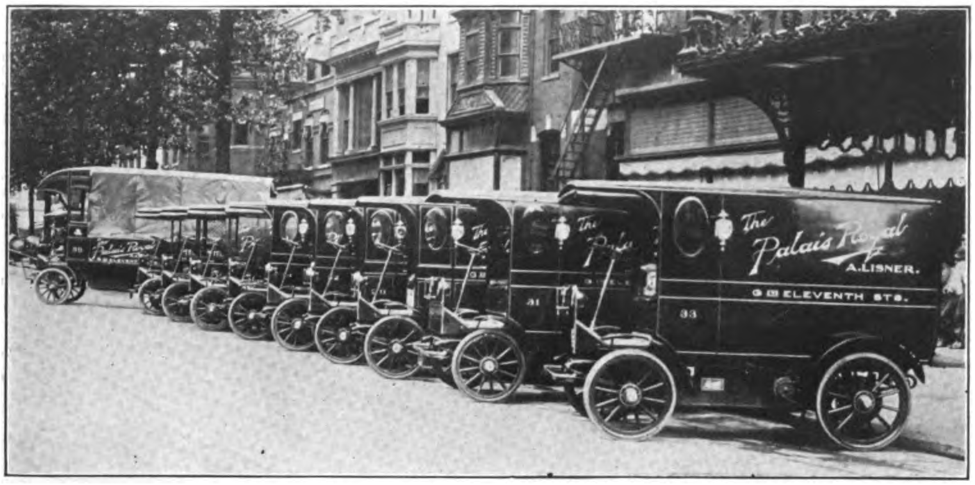
It will be understood that there are no fixed charges or depreciation included in the above figures, but it will be seen that with the same volume of contract work as was required during the first three months the saving is approximately $1.23 a day, which will probably be sufficient to meet all the expense of overhauls and replacements, as the company has its own machine shop and mechanics capable of doing whatever mechanical work may be needed. Not only this, but it is believed that there will be a considerably greater gain in earning capacity, as the company can deliver in a much larger area, and the truck will be sufficient to keep pace with the business development for several years in all probability. The machine has on some days handled from 15 to 18 tons of steel, more than twice the tonnage that could be hauled with mules.

DEPARTMENT STORE ELECTRIFIED.

Palais Royale at Washington, D. C., Has Delivery Fleet of 10 Detroits.

The Palais Royale department store at Washington, D. C., of which A. Lisner is proprietor, has a delivery equipment of 10 Detroit wagons, built by the Anderson Electric Car Company, Detroit, Mich., and for its service in that city uses no other vehicles. The first two machines ordered were delivered early in 1911, and were used with horse wagons. These proved to be so satisfactory that in the latter part of the same year two more wagons were purchased, and some of the horses were disposed of.

The four wagons gave even greater satisfaction as experience was gained and in 1912 a 3000-pound wagon fitted with a body designed for carrying furniture was ordered, and this spring five more wagons were purchased, this making a fleet of 10, six of them being 1000-pound chassis fitted with panel bodies, three 2000-pound chassis fitted with panel bodies, and the furniture wagon. The loading space of the 1000-pound wagons is 73 inches length and 43 inches width, of the 2000-pound wagons 80 inches length and 48 inches width, and the furniture wagon has a body 13.5 feet length, six feet width and 6.5 feet height. All of the wagons are equipped with Edison batteries.



The Fleet of 10 Detroit Electric Wagons in the Delivery Service of the Palais Royale, a Washington, D. C., Department Store.

The results from this delivery equipment have been very satisfactory, the cost being reduced as compared with horse wagons, the customers are better served, and the excellent appearance of the machines has an advertising value that has been materially productive.

Seagrave for Athol, Mass.—Athol, Mass., has installed a Seagrave combination hose truck, made by the Seagrave Company, Columbus, O., at a cost of $5500. It is figured that the machine will pay for itself in a short time, on the difference in the cost of maintenance between it and the horse drawn machines it supersedes.

ELECTRIC CLUB'S OUTING.

Boston Vehicle Men Guests of the Boston Edison Company at Braintree.

The annual outing of the Electric Motor Car Club of Boston took place July 17 at the New England Kennel Club's house at Braintree, Mass., where the members to the number of 75 were the guests of the Edison Electric Illuminating Company of Boston. The members were taken to the club by automobile and while the Electric Vehicle Victors and the Central Stations Stars were playing at baseball another group was shooting at clay pigeons. The Victors won by a score of 17 to eight, and the honors of marksmanship fell to H. S. Hale and John L. Snow.

The dinner was extremely satisfying, and following this three applications for membership were acted upon favorably and then came a series of brief speeches by President Edgar of the Boston Edison Company, Fred M. Kimball of the General Electric Company, President Whitesides of the Stevens-Duryea Company, General Manager Atkins of the Boston Edison Company, D. C. Tiffany and John L. Snow. Albert Weatherby of the Anderson Electric Car Company thanked the Boston Edison Company and H. S. Hale of the New England Kennel Club for their hospitality, and General Manager Atkins of the Boston Edison Company announced that the company had decided to offer a handsome silver loving cup, to be competed for by baseball teams composed of members of the club and allied interests. A committee of three, of which Col. S. R. Bailey is chairman, was appointed to arrange for the organization of the clubs and fix a playing schedule.

KISSELKARS IN TEXAS SERVICE.

Two Machines Will Carry Mail, Freight and Passengers in Kimball County.

The Kissel Motor Car Company, Hartford, Wis., has sold to the Southwestern Motor Transit Lines of Texas, a five-ton KisselKar combination express and freight truck and a 1.5-ton passenger and mail car. These machines are used in regular trips between Menard and Junction, Tex.

Connecting with a railroad at Menard, the machines will penetrate Kimble county 30 miles to Junction. The company has contracts with the United States government to carry the mail and with the municipality of Junction to handle all city freight and supplies. Kimble county is in southwest Texas and not a railroad crosses its borders.

ELECTRIC VEHICLE PRACTISE.

Principles of Primary and Secondary Cells and the Functions of the Metals and Solutions Composing Them---Fundamentals of Chemical Action and Reaction in Charging and Discharging---Some Early Types of Plates.

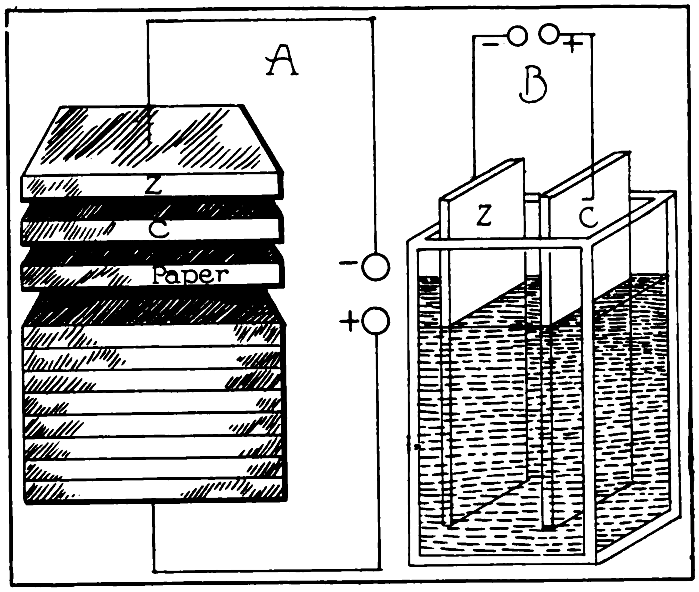
By William W. Scott.

THE energy by which the electric vehicle is propelled is drawn from a battery of cells in which electric current is stored or charged. Strictly speaking, this is an accumulator for current mechanically created, and then this current is at the will of the operator transformed to mechanical power. The battery, as it is accepted by the electrical world, is composed of secondary cells, for a primary cell is that which generates current chemically, and which has decidedly limited capacity and power. It is practical, however, to build batteries of secondary cells of very large size, sufficient in fact to be used as a reserve for lighting and power plants. Naturally these cells correspond to the proportions of the batteries. There is no variance of principle in the construction and use of secondary cells, although the materials may differ from every point of view.

Literally, the functions of a secondary cell are chemical action and reaction, resultant from the flow of a direct current of electricity through the cell for a stated period. The capacity of the cell is limited and it will not yield in useful work all of the energy used in charging it. That is to say, that the output of power will not equal the input. The efficiency of the cell is comparatively good, and it is a fact that the capacity of the earliest constructions were practically, if not quite, the equal of those of the present day. The function of the lead battery cell is principally of the nature of the materials and it is susceptible to but little change, by alteration in design, etc. The endeavor of electrical engineers, or more properly battery engineers, has been toward improvement in the reduction of weight and increasing the durability of the element.

The principle of the voltaic pile is probably the most familiar of any electrical device. This is constructed of plates of copper and zinc placed in regular order, each pair of plates being separated by a layer of absorbent material, such as blotting paper, dampened with acid. The plates may be copper first and zinc second, and then a sheet of paper, this order being followed through until the pile is completed. When finished the outer disc at one end is zinc and at the other copper. One outside or end disc is the positive and the other the negative. Were wires connected with these two discs and these wires coupled there would be a flow of energy through them that would be proportionate to the size and number of the plates. This current would result from the galvanic action of the two dissimilar metals.

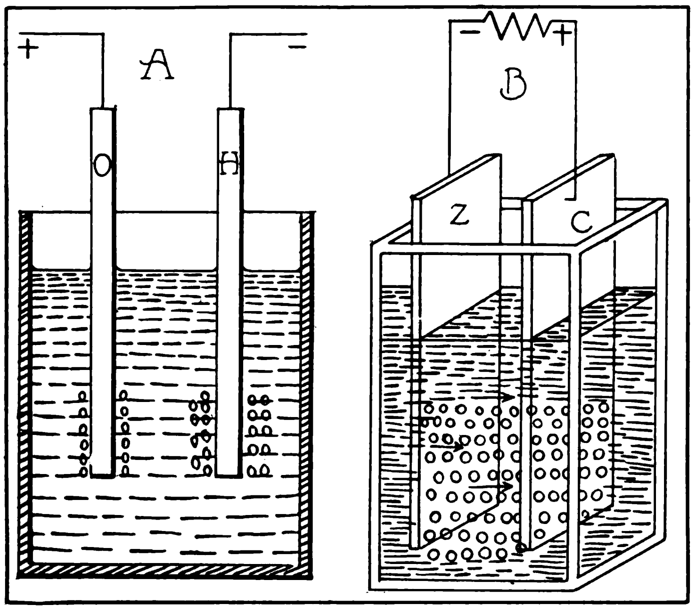
There are such decided limitations to the voltaic pile, so-called, that the voltaic cell was next created, this being a jar of glass or non-porous earthenware in which in a solution of sulphuric acid are suspended a sheet of copper and a sheet of zinc, each plate of metal having a wire connected with it. When these two wires are joined a current of electricity will flow through them, and the direction of the flow will be from the copper to the zinc. The diluted sulphuric acid that constitutes the electrolyte will attack the zinc plate and will in time dissolve it, or at least that portion of it exposed to the solution, but there will be no material influence manifested upon the copper, which serves merely to conduct the electric energy. The copper or passive plate is termed the positive, and the zinc the negative, but these terms are in reality



The Voltaic Pile and the Voltaic Cell: A, the Voltaic Pile of Alternate Sheets of Zinc, Copper and Acidulated Paper; B, the Cell of Zinc and Copper Plates and an Electrolyte of Dilute Sulphuric Acid.

applied to the poles of the cell and not to the plates themselves, which are exactly the reverse of the accepted designations. That is, it is the gradual consumption of the zinc by the acid that creates the current of electricity, and the energy originates in this plate instead of the copper element. Consequently the zinc plate is the positive or productive agent. Similar results may be obtained by the use of carbon and zinc elements and a solution of sal ammoniac, and with other combinations of metals and solutions. The action that takes place in cells of this character is a union between dissimilar substances to form a new product.

The action of the electrolyte on the zinc plate will produce zinc sulphate, and this production is accompanied by the creation of hydrogen gas. This gas is



A, Illustration of the Formation of Oxygen Gas and Hydrogen Gas at the Positive and Negative Plates During the Decomposition of the Water in the Electrolyte; B, the Manner in Which the Positive Plate Is Polarized by Hydrogen Gas.

created in the form of "ions" or atoms, and these atoms will pass through the electrolyte from the zinc plate on which they originate and will manifest themselves in the form of accumulations of tiny bubbles on the copper plate, to which they are attracted, until the hydrogen gas on the positive plate has such volume that it will practically prevent the movement of the electric current. When the accumulation of hydrogen gas has so prevented the movement of the current the cell is said to be polarized. This process of polarization is gradual and the current diminishes as the volume of hydrogen gas increases. In a sense the gas insulates the positive plate against the current of electricity. It is possible to observe the accumulation of the hydrogen bubbles upon the positive plate. As the electrolyte attacks the zinc the temperature of the cell will rise.

It is practical to depolarize a cell—that is, to remove the hydrogen gas from the positive plate—by mechanical, chemical or electro-chemical means, and all primary cells employ one of the three methods to bring about depolarization. The mechanical depolarization is accomplished by agitating the electrolyte, by blowing air through the electrolyte, and by using rough plates, which divert the course of the hydrogen gas to the surface. The chemical method is by combining a chemical with the electrolyte that will create oxygen, a gas for which hydrogen has a great affinity, which will unite with the hydrogen and prevent its accumulation. The electro-chemical method is in the use of two solutions that normally are separated from each other by gravity. For instance, an element of zinc is suspended in a jar and an element of copper is placed at the bottom, and around this is heaped a number of pieces of copper sulphate. The two solutions are sulphate of zinc, which is lighter, and sulphate of copper, which is heavier. The hydrogen gas created at the zinc element is attracted toward the copper, but as it enters the sulphate of copper solution a particle of pure copper is substituted for it, and this copper particle descends and attaches itself to the copper element. Thus there is a constant deposit of copper and an absence of hydrogen gas, which means uninterrupted strength and activity of the cell.

Such cells as have been described are primary and the energy that will be produced in them is dependent upon the elements and the solution, as well as the proportions. But it is evident that primary cells have neither the capacity nor the endurance that are necessary to serve for vehicle propulsion. The secondary cell has been developed from the experiments of Gautherot, who in 1801 found that when two plates of silver or platinum were suspended in an electrolyte and connected with the terminals of an active primary battery and the current permitted to flow, a current of lessened strength would flow when the two plates had been connected, after the connection with the primary battery had been broken. In other words, the primary battery created an activity in the second cell.

An electrolyte made of sulphuric acid diluted with water was used and it was found that the resistance of the electrolyte decreased up to a certain point as the proportion of acid was increased. The current passing through this electrolyte decomposed the water, the oxygen gas bubbles forming on the plate coupled to the positive pole of the galvanic cell, and the hydrogen gas bubbles forming on the plate coupled to the negative pole of the primary cell. As the oxygen could not attack either of the plates the gas escaped from the electrolyte when the plates were covered with bubbles. From this point no more energy could be accumulated. When the current from the primary cell was broken and the two plates were connected by wires a current was created by the recomposition of the gases to form water.

Analyzing the process, it will be seen that it is in a practical sense a reversal of that by which a current is created in a primary cell. Hydrogen gas is formed

on the negative plate, which is the cathode or outlet for the negative current during the period the primary battery is connected. Simultaneously oxygen is created at the positive plate. Both of these gases are atomized into "ions" and these flow through the electrolyte, the oxygen from the positive plate to the negative, and the hydrogen from the negative plate to the positive. There is a surplus of hydrogen from the fact that water when decomposed will yield twice as much hydrogen as oxygen. This process will continue as long as there is a flow of hydrogen gas "ions" from the negative to the positive plate, and this is the discharge of the cell. When the recomposition of the gases has been accomplished activity is ended because the gases do not combine with the metal of the plates. This explanation makes clear why this form of cell is known as secondary, and the term applies to the principles established by Gautherot.

As there was, as stated, a limit to the capacity of the cell with the silver and platinum plates because oxygen will not have the same influence upon them as other metals, to construct cells that would be practical with reference to capacity, weight and endurance it was essential to use elements in which the active material would be practically insoluble in the electrolyte at all times, so that they might be changed during the period of charging and brought back to their original condition during the period of discharge. For many years lead or compositions of lead were the only practical metals that gave substantial results in practise, and to this nickel and iron were added with the construction of the Edison alkaline cell. In practical operation lead is highly influenced by oxygen, but it is not completely restored to its original form and eventually it will lose its restorative qualities, and, consequently, its capacity. For all purposes, however, the lead plate cell will endure exceedingly well, and with the care and attention that should be given, a lead plate element will afford highly satisfactory service. It is possible to obtain maximum efficiency from an exhausted cell by renewal of the plates.

The secondary cell was not regarded as practical until developed by the experiments of Gaston Plante, a noted French electrician, who about 1860 succeeded in producing capacity. The original construction was in the form of strips of lead wound spirally, these strips being separated by strips of sheet rubber or canvas, used with dilute sulphuric acid as an electrolyte. When a primary cell was coupled with this type of cell hydrogen collected on the surface of the negative plates or strips, but instead of the oxygen collecting on the positive plate, as with Gautherot's silver and platinum cell, in the form of bubbles the oxygen caused peroxide of lead to form on it. But to bring about the necessary changes in the metal the plates were "formed" by charging and discharging the cell, using each terminal alternately as the positive and negative, and varying the periods of charging and discharging.

The forming process required something like 60 days, and the effect was that the lead peroxide accumulated on one plate was dissipated, the plate changing in color from brown to that of metallic lead, this plate becoming porous and sponge like in texture. As peroxide was reduced on this plate it was formed on the surface of the other plate. The porous, spongy lead plate was the negative and the peroxide-coated plate the positive. The porous nature of the negative plate

Frames of Unglazed Porous Earthenware, the Square Containing the Active Material and the Channelled Member Serving as a Separator, Used with Sheet Lead Electrodes.

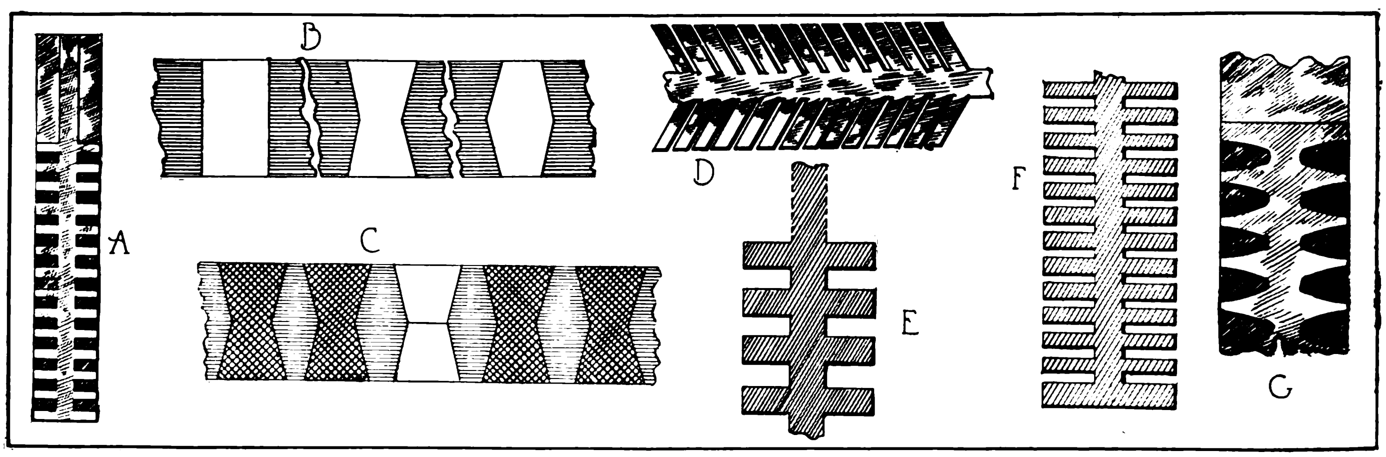
afforded a very large area in contact with the electrolyte, which exposed a greater surface for action and brought about the cell capacity. The efficiency of the plates formed by the alterations of the charging current was high, but the great objection was to the length of time and the expense necessary in forming them, as well as the fact that, due to poor mechanical construction, the plates did not long endure. As a substitute for this the metal was subjected to chemical treatments with a view of hastening production and lessening the expense, and the different engineers who followed in this work utilized varying methods and materials in their constructions, retaining, however, the lead as the basis.

The method of forming plates by electrolytic action, or the reduction of the material to the required oxide, is essential. The process of making plates that was covered by patents granted in this country to Charles F. Brush, was also created in France by Camille Faure, and this type of plate is in general use today in practically all lead or acid cells used for automobile vehicle service, whether for ignition, lighting, propulsion or other purpose. Such plates are known by the name of the French electrician, and Brush's name is seldom heard of in connection with the process. The Faure method has been known since 1880, and it has been developed from time to time by different manufacturers and engineers, the methods usually being carefully kept from publicity because of qualities that each particular production is supposed to have. In cells used for stationary purposes the Plante type of plate is very generally utilized, and in some instances both the Plante and Faure constructions are used, the plates being alterations of each form.

The Faure type of plate is primarily a frame constructed of lead or of a composition of lead and antimony to give strength, and the frame may be one of numerous forms, the purpose being to have a large measure of conductivity and such form as will retain the active material applied as paste and hardened. In some instances the plates are perforated, in others are slots or openings, and sometimes they are grids, the design being dependent upon opinion as to efficiency and durability. The paste is known as the active material and in the first instance red oxide of lead was used, this being changed by the forming current to the peroxide of lead for the positive plate and spongy lead for the negative plate. Later on red lead oxide ($Pb^{3}O^{4}$) was used for the positive plate and lead monoxide or litharge (PbO) for the negative. The early types of grids or frames were heavy and thick, the area of surface exposed to the electrolyte comparatively small, and numerous faults were developed.

One was the tendency of the frames to buckle or bend and the plates to contact, and another was the disintegration of the active material, lessening the surface area, diminishing the capacity and the length of service, while the particles of free active material caused short circuits if caught between the surfaces of two plates. In some instances positive plates are made with a series of rolls of lead ribbon forced into openings in the frames, and these are formed by the use of an electric current. Negative grids are sometimes formed by casting the frame around blocks of composition that are afterwards treated with chemicals.

It is impractical to describe the different types of construction or the processes that are made use of by manufacturers, but generally speaking the plates are designed to have the qualities of lightness, large surface area, strength and durability. Much depends upon the formation of the frames or grids, which are usually made with an arm or lug extending upward



A, Cross Section of a Brush Plate; B, Forms of Pockets Used by French Makers of Plates of the Faure Type; C, Forms of Pockets Used by English Makers of Plates of the Faure Type; D, Cross Section of a Plate Rolled from Lead for Plante Formation; E, Channelled Plate for Plante Construction; F, Another Form of Channelled Type; G, Form of Channel in One Design of Tudor Plate.

from one corner, the purpose of this being to engage with straps that will hold the plates in a fixed position in the cell. With some types of cells the arm or lug is so shaped that it may be suspended from the side of the jar or container, and others are supported by bolts or rods, each group of positive and negative plates being separate.

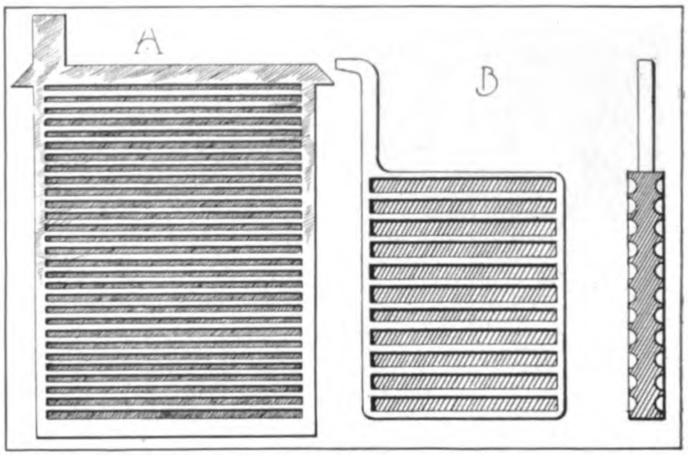
There is one exception to the constructions that have been outlined, and that is the "Ironclad-Exide" battery, made by the Electric Storage Battery Company, in which the positive plate consists of lead top and bottom members connected by vertical rods that serve as conductors. Each rod is surrounded by peroxide of lead, the active material, that is retained by a thin shell or quill of hard rubber in which is cut a large number of horizontal slits, through which the electrolyte is brought in contact with the active material. It is claimed for this form of plate that the active material is retained in the rubber quills and, as very little if any of it is lost through chemical action, that the plate has unusually long life and capacity the equal of any other construction.

The cell may be contained in a glass, porcelain or hard rubber jar of such size as may be desirable, and the proportions are apparently determined more by experience than by any definite requirement as to volume of solution per surface area. Some jars differ from others, and generally all of them are made today with one or more ridges raised above the bottom of the cell on which the plates may be supported. It is necessary to provide a space below the plates, for the active material will gradually disintegrate and the particles will fall to the bottom. Each cell in use for a considerable period will have at the bottom a quantity of sediment that will resemble soft mud. Should such an accumulation reach the bottom of the plates it will short circuit them and the cell will be useless until the sediment has been removed.

Normally the frame of the negative plate is lighter than that of the positive plate. The assembly of plates is known as an element, and the positive plates are in one group and the negative plates in another, there being negative plates outside, with a positive plate between each two negatives, each about .1875 inch apart. That the plates may not contact with each other separators are ordinarily used. These separators are of wood and hard rubber. The wood has been found to be a thoroughly dependable material—in fact, nothing that is a satisfactory substitute is known—and before using this wood is treated with chemicals to remove substances which would cause complications were they to enter into the electrolyte. The wood separators are made with a series of shallow channels extending longitudinally in one side or face, and the other is smooth. The first outside plate is a negative, and the flat or smooth side of the wood separator is placed in contact with the negative plate. The rubber separator, which is a very thin sheet and perforated with many small holes, is placed between the wood separator and the positive plate, the reason being that the wood separator would char from the action of the positive plate were it in contact with it. This arrangement of the plates and separators is followed through the assembly.

With reference to the manner of assembling it will be seen that the plates are very close together, with the wood and rubber separators between, all the positive plates being retained by one series of lugs in a strap, and the negative plates being similarly secured. The purpose of the channels in the wood separator is to permit a free circulation of the electrolyte between the wood and rubber, that it may have access through the tiny perforations to the positive plate, and besides protecting the wood separator the rubber separator also prevents the washing action of the electrolyte assisting in the disintegration of the positive plate.

As may be assumed the space between each plate is small and the action is between each plate of each series, the united action of each series being the effective work of the cell. When the plates have been assembled and the electrolyte has been placed in the cell, the cell must receive attention. The electrolyte



A, One Type of the Plate Used in the Tudor Battery Cell, a Well Known European Construction; B, Another Type of Tudor Cell Plate, Showing Side and Cross Section—The Grooves Were Packed with Active Material.

is a solution that is approximately 40 per cent. sulphuric acid and distilled water. The first care the cell should have is charging, and the result is that the current, passing from each positive plate through the electrolyte to the negative plate, decomposes whatever lead sulphate may be present and transfers all of the oxygen from the negative plate to the positive. When the charging is completed the negative plate is free from oxide and is pure sponge lead, and there are no oxides in the positive plate other than peroxide, with the possible presence of some sulphate. At this time the electrolyte has its highest specific gravity. The positive plates are dark brown in color and the negative plates are dark slate color.

On the discharge of the cell the effect of the electric current is to decompose the water in the electrolyte, and both oxygen and hydrogen are created, the oxygen at the negative or sponge lead plate and the hydrogen at the positive or peroxide plate. When these gases are created they are more active chemically

than before and are more readily combined with other substances. The more active hydrogen will combine with oxygen in the lead peroxide, forming water, and the reduction of this oxygen reduces the degree of oxidization of the lead peroxide and transforms it into lead oxide. At the same time the oxygen created at the negative plate combines with that plate to form lead oxide. Thus it will be seen that the tendency of the two plates is to become alike in proportion to the discharge, and so the complete discharge would transform them both to the same substance. The radical of the acid combines with the active material of each plate, creating lead sulphate, and this loss of acid from the electrolyte reduces the specific gravity. The sulphate is increased as the cell is discharged, and when the cell has been practically discharged the sulphate is present in greatest volume. When fully discharged the positive plates are a chocolate brown in color and the negative plates are a slate color. When the plates are sulphated the positive plates are drab in color.

To consider the chemical action of the cell for a moment. Many engineers are thoroughly agreed as to certain general results, but as to precise charges there is a diversity of theory. The electrolyte used for the cell in service is a solution of 40 per cent. sulphuric acid and 60 per cent. pure water. The positive plate is peroxide of lead and the negative plate is spongy lead. When the plates, or element, are first placed in the electrolyte sulphation will be begun without the action of the electric current.

When the charging of the cell is begun the decomposition of the water of the electrolyte is begun and oxygen is formed at the positive plate and hydrogen at the negative plate. At the positive plate the oxygen enters into a combination with the lead oxide, adding oxygen and changing the surface of the plate to lead peroxide, while at the negative plate the hydrogen combines with the oxygen in that plate to form water, so that the oxygen is abstracted from the plate and the plate transformed to lead. In a chemical expression of the action the equation is:

CHARGING.

Positive Plate.

O	+	$H^{2}O$	+	$PbSO^{4}$	=	$H^{2}SO^{4}$	+	PbO^{2}
Oxygen		Water		Sulphate of Lead		Sulphuric Acid		Lead Peroxide

Negative Plate.

H^{2}	+	$PbSO^{4}$	=	$H^{2}SO^{4}$	+	Pb
Hydrogen		Sulphate of Lead		Sulphuric Acid		Lead

The chemical equation of the discharge may be thus expressed:

DISCHARGING.

Positive Plate.

PbO^{2}	+	$H^{2}SO^{4}$	=	$PbSO^{4}$	+	$H^{2}O$
Lead Peroxide		Sulphuric Acid		Lead Sulphate		Water

Negative Plate.

Pb	+	$H^{2}SO^{4}$	=	$PbSO^{4}$	+	$H^{2}O$
Lead		Sulphuric Acid		Lead Sulphate		Water

The equations that have been stated do not indicate the numerous changes that will take place in the charging and discharging of a cell. The charging is begun with both plates showing practically the same condition with the presence of sulphate of lead, and with the dissipation of the sulphate of lead the plates are transformed, the tiny crystals of sulphion being broken up and uniting with the water increases the volume of sulphuric acid and the specific gravity of the electrolyte becomes higher. When the cell has been charged the sulphate of lead has disappeared and volume of acid is greatest. With the discharge of the cell, volume of sulphuric acid decreases and the specific gravity lessens. The fact that lead sulphate has a high resistance and serves as an insulator, should be understood, and that the change of the active materials of the plates from lead peroxide to lead sulphate and from sponge lead to lead sulphate increases the volume, so that too great a degree of lead sulphate might distort or break the plate frame or dislodge the active material.

The voltage of the storage cell is dependent upon the metals constituting the plates or elements and the density of the electrolyte, and the potency of the lead battery is the difference existing between sponge lead and lead peroxide. This difference between the elements in theory ought to be relatively the same until the reduction of the sponge lead and the lead peroxide is accomplished, but practically this is not realized.

(To Be Continued.)

EDISON "IN MEMORIAM."

A Clever Booklet Addressed to the National Electric Light Association.

The Edison Storage Battery Company, Orange, N. J., has published a clever and interesting booklet which is described as presenting facts that did not get into the "proceedings," and containing some of the features of the Chicago convention of the National Electric Light Association, and stories that were told, but not recorded, referring particularly to the Edison storage battery. Usually special booklets are published prior to conventions, but this differs from the general policy regarding publicity and it has been prepared with a view of having sufficient news value to impel the attention of all who shall receive it. The booklet is being sent to every central station in the country and to the personnel members of the commercial section of the National Electric Light Association.

The booklet is admirably arranged and capitally illustrated. It deals briefly with numerous instances of the use of the Edison battery, and brings to the attention of the reader facts relative to service that have been established in a practical way. These statements are equally as interesting to the users of vehicles as they are to central station men because they deal with motor vehicle efficiency and economy. Incidentally the stories as a rule are surprising, though they do not deal with extremes.

An organization of motor truck owners and salesmen is now being perfected in Boston by President D. C. Fenner of the New York Motor Truck Club.

MOTOR TRUCKS FOR ICE HAULAGE.

Extremes of Conditions Experienced in Two Years Contrast the Efficiency of Machines Used by the Providence Ice Company in Regular Service.

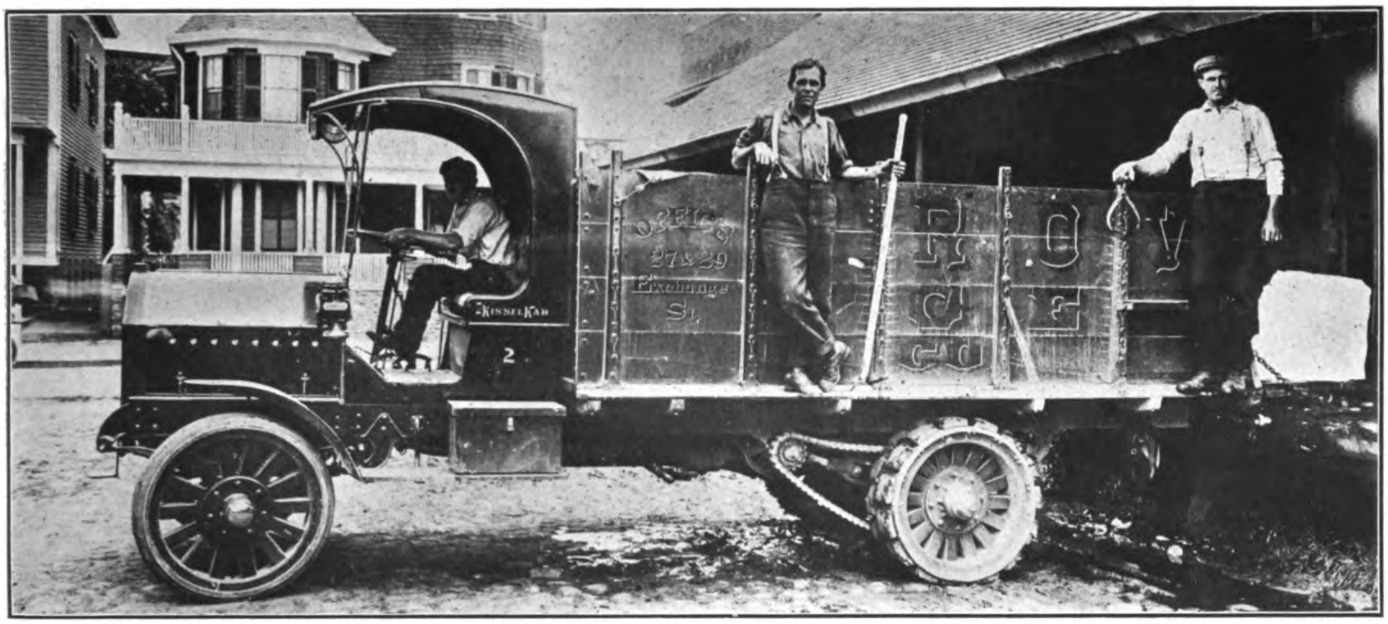
THE sale of ice is a business in which many variables are met with—so much so in fact that those who have the greatest experience maintain that it is absolutely useless to even strike an average and from this attempt deduction as to supply or demand. While this statement will apply to one concern, it is also a fact that conditions will differ in each locality, and it is impossible to find two where these factors may be regarded as alike.

The consumption of ice varies greatly, to be sure, and while there is a limited demand during the cold months of the year the greatest output is in the four months when the heat is intense. Assuming that the quantity used in the summer is 100 per cent. then there is a shrinkage to from 15 to 20 per cent. in the winter. Ice is used constantly by many concerns dealing in perishable goods, or in stock that must be kept at a low temperature, but it is evident enough that the quantity supplied by the ice dealer will vary according to the conditions of the weather.

This condition applies to a greater or lesser degree throughout the country. The demand is lowest during the winter and it increases gradually to the summer and then diminishes. There is, of course, a dependable patronage from the business houses, but practically every dealer in ice regards as the certain source of profit the sales to the families, where ice is delivered regularly and where the price paid is large as compared with the deliveries in what may be regarded as quantities. For instance, 10 cents for a 25-pound piece of ice will yield $8 a ton, and while it costs a considerable percentage of the price to deliver this, and it is necessary to consider many items of expense in computing the net return, there is no doubt whatever that the profit is attractive and sufficient.

Aside from the normal variation of the demand of the constant consumers the family business may be said to begin about May 1 and reach its lowest about Nov. 1, covering a period of about six months. It is not possible for the ice dealer to attempt to do business without adequate delivery equipment, and it will be understood that the requirements are exactly proportionate to the volume of business transacted. In other words, the ice dealer in the northern half of the United States has need of from four to six times as many wagons in midsummer as in midwinter.

But there are years when but little ice is harvested and then the dealer has to meet entirely new conditions. The system and methods that were found satisfactory and economical will not suffice and it is necessary to deal with the business from entirely new angles. This has been the experience of the Providence Ice Company, Providence, R. I., and the fact that but little ice was harvested in Rhode Island last winter has a material influence so far as the service which it is obtaining from its motor trucks is concerned.

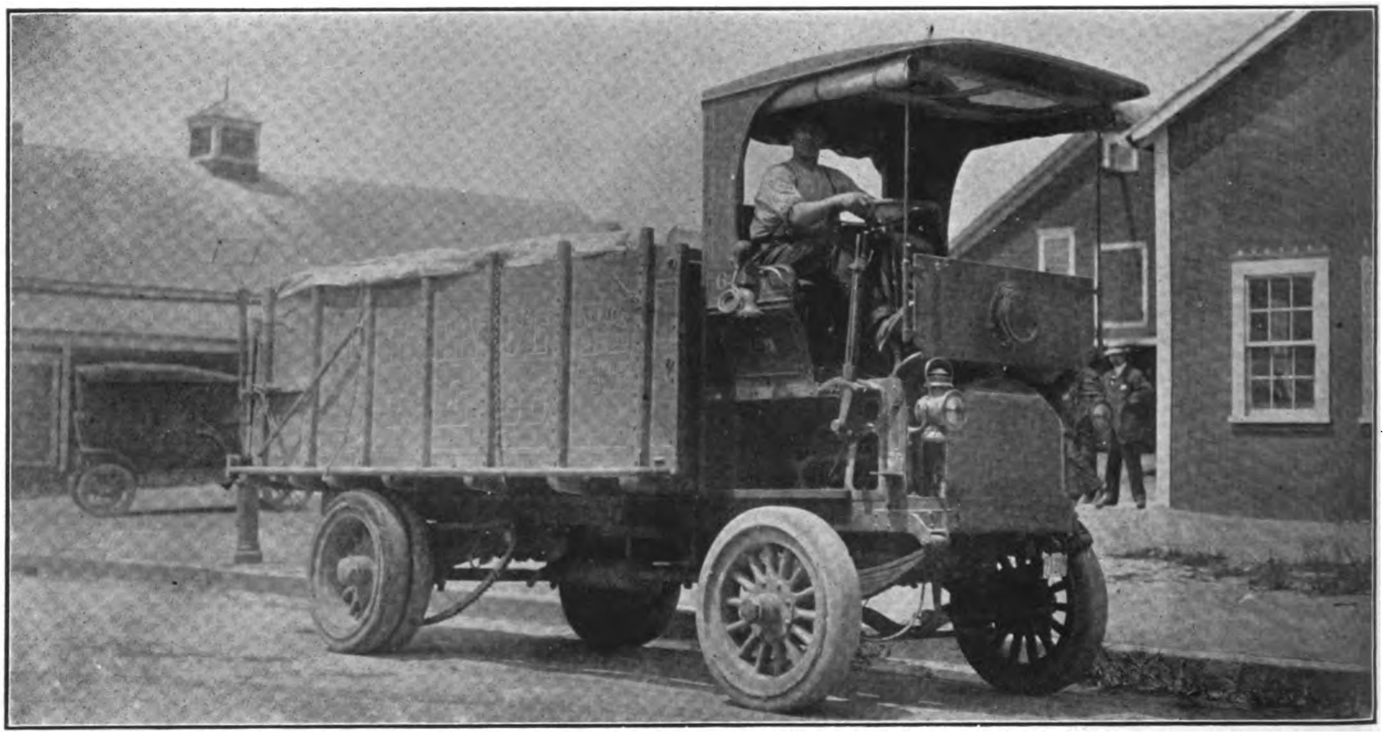


The Four-Ton Kissel Truck in the Service of the Providence Ice Company Unloading Ice at the Burnett Street Supply Station, Hauled from the Railroad Yard.

This company handles about 225,000 tons of ice annually, and the greater part of this is harvested within 25 miles of Providence, usually at large ponds that are convenient to railroads. It is evident enough that if ice were within six or eight miles from the places of distribution and it were necessary to haul it by highway the cost would be much greater than were it

hauled several times the distance by railroad. Not only this, a very advantageous freight rate can be obtained when the contract is made on a basis of 10,000 tons, for instance. For this reason ice is generally harvested where it can be easily transported, and while it is not always practical to have spur tracks to the ice houses, and it may be necessary to haul the ice from the houses to the cars, this is not a condition that materially influences the price.

Some of the ice sold by the Providence company is generally harvested in Massachusetts, and though the bulk of the harvest is obtained beyond a 15-mile radius from the centre of Providence, this is because of the difficulty of obtaining ice nearer. Many ponds are polluted and the ice cannot be used unless for cooling. That is, it is unsanitary for any purpose where it would be brought in contact with food or drink, although it might serve for reducing temperature to preserve perishable goods. There are a number of ponds, however, at distances from the city where it is practical to haul the ice, even though the cost is as much or even more than the expense of securing an equal quality further away.



The Providence Ice Company's Five-Ton Mack Truck, Now in Its Third Year of Service, Used for Haulage from the Railroad Yards to the Supply Stations.

It was the cost of hauling ice from these ponds by horse teams that caused the Providence Ice Company to purchase its first truck in 1911, this being a five-ton Mack machine. The company has stations located about the city and the suburbs, and in the city are the Mashapaug and Wanskuck ponds, where ice is harvested. The ice from the former is used only by packers and for refrigerating. At Knightsville, in the city of Cranston, and East Providence and at Posegansett, in the town of Warwick, are three other ponds and ice houses. At all of these ice houses are stables and from these points distribution is made. In addition there are supply stations at Ethel and Burnett streets in Providence, where there are stables and which are also the central points from which distribution is made in the sections of the city in which they are. In addition the company has supply stations at the railroad yards at Harris avenue and Promenade street, and the ice received in cars is distributed to the business sections of the city.

Normally ice is harvested at Hughesdale, where there are two large ice houses, and at North Providence, where there are two others. The Hughesdale ice houses are respectivly four and 4.25 miles from Ethel street and five and 5.25 miles from Burnett street and Harris avenue. The North Providence ice houses are about four miles from the Harris avenue depot. The greater part of the family trade is ordinarily supplied from Hughesdale ice, which is hauled to Ethel and Burnett streets, and the sections in the vicinities of Knightsville, East Providence, Posegansett and Wanskuck are supplied from those stations. The Mashapaug ice is usually delivered in loads to those requiring large quantities.

The maintenance of the supplies at the Ethel and Burnett street stations was the troublesome problem. It was hauled from the Hughesdale houses by four-horse teams and carts carrying four tons, and two round trips to either station, one to each station, were all that could be done by one outfit. Two round trips to Burnett street were 21 miles, and one to each station 19 miles, or two to Ethel street 17 miles, and it was out of the question to attempt to do more. With the very economical system of maintenance of its equipment, and paying a driver $2.25 a day, the cost of a four-horse team and wagon was figured at $7 a day, and this brought the expense of haulage by animals to

87.5 cents a ton at a very low estimate.

With relation to the North Providence houses the haulage distance is approximately 16 miles for the round trip, and two loads of four tons were the most that could be hauled by a four-horse team and wagon. The cost of haulage was the same, but figured on the basis of ton-miles the expense was greater. These houses were regarded as reserve pure and simple, and though filled each year the ice was often allowed to melt because of the expense of hauling it.

The first year the Mack truck was used it hauled ice from Hughesdale to the two supply stations, with occasional trips to the Harris avenue depot. It was found practical to make five round trips, carrying five tons, or the equivalent of this work, and figuring the cost at $13 a day this made the expense for haulage 53 cents a ton, a saving of 34.5 cents a ton as compared with the horses. Besides this there was the saving of ice, there being a shrinkage of but one per cent. as contrasted with five per cent. with animals, and there was a very large reserve in the truck that was available if needed. The showing made with the truck resulted in the purchase of three KisselKar machines, two four-ton trucks and a 1500-pound wagon in 1912, and these machines were used through the year. The work that was done with the three trucks was largely in hauling the ice from Hughesdale to the Ethel and Burnett street stations and to the Harris avenue depot.

The Mack truck hauled an average of five five-ton loads daily, this giving a total tonnage of 25 for the day and 150 for the week, and this showed a cost of approximately 53 cents a ton, allowing the expense of the truck to be $13. One of the other KisselKar trucks in the same work averaged five trips three days of the week and six the other three, or a total of 33 loads in all with daily tonnage of 20 or 24 tons and a total of 132 for the week. Figured on a daily expense of $12 this made the cost about 54.5 cents a ton. The other truck averaged five round trips daily, with a tonnage of 20 each day and of 120 for the week, and with a cost of 60 cents a ton. The KisselKar delivery wagon was utilized for making special and emergency trips, doing the work of more than three single wagons, being worked every day in the week. Because of the character of the work done with this machine it was impossible to make the same comparison as has been made with the trucks.

It has been the experience of the company that it is not possible to use the trucks for other than supply service or delivery of considerable quantities of ice, and it is evident that there is not a sufficient volume of load orders to justify maintenance of truck equipment for this purpose alone. For this reason such delivery can only be made incidentally. So far as the use of motor wagons for the usual route work is concerned it is not believed by the officials of the company that this is practical. The reason is that the routes are made up with the customers as close as is possible, and much of the time of the driver and helper is taken up by handling and delivering the ice, during which time the wagon is idle. The use of the KisselKar delivery wagon, however, is with sometimes long distances between stops, so that it is possible to realize the fullest benefit of the speed of the machine.

The present year the conditions that might be normally expected have been completely reversed. First of all, but little ice was cut on any of the Rhode Island ponds, either near or distant from Providence, and instead of the company realizing a benefit because of the superiority of the trucks over horses in the haulage from the Hughesdale and North Providence ice houses, and the saving of a very substantial proportion of the cost of transporting the ice from those ponds to the city supply stations, this economy has been nullified by the lack of local ice. Some ice was cut, to be sure, but it was a comparatively small harvest, and practically all of the ice used in Providence has been brought in by railroad, in some instances being hauled several hundred miles.

This ice is received at the Harris avenue and Promenade street depots and these will hold but a small supply. Of course the ice is received daily and is unloaded from the cars at the depots. The trucks are used to haul it from these two depots to the different supply stations, and as the longest haul will not exceed 2.5 miles it will be seen that there is not the economy there would be were there the same mileage necessary as last year. There is a saving in the shrinkage of ice during haulage, and ice is unusually valuable this year. Because of the increased price charged for ice greater economy is observed with its use and there is not the same quantity used as in years when it was less expensive, and this is a considerable factor as well. Naturally the company does not ship any material excess to Providence because there would be more shrinkage in the event of delay and in handling, and why this is so is understood when it is known that a carload of 20 tons will lose sometimes as much as 50 per cent. weight in transit, and the ice is not always in condition to be handled advantageously. Not only this, because of the heavy loss and the high cost at the place of cutting no more than is necessary to meet the requirements is shipped.

The condition limits the tonnage and as the hauls are short it is possible for two of the trucks and the delivery wagon to haul the ordinary daily supply for each station, while one of the trucks is usually kept in reserve and is only utilized in the event of emergency demand or accident. As will be understood from these statements the full economy possible with the trucks is not realized, and this means a proportionate loss when the company cannot use its labor saving equipment.

But there is this fact to be taken into consideration, however, and that is that there is little probability of a season so completely reversing normal conditions being again experienced in a number of years. The same effect may be applied to practically the entire equipment of the company for harvesting and storing ice, for this has been unproductive and has been an ex-

pense from every point of view. The company has its own repair shop, well equipped with machine and hand tools in connection with its garage, and all of the ordinary work is done by the mechanic who has charge of this work. The machines are well kept and deterioration is not permitted. The cost of operation is approximately the figures stated for the four and five-ton trucks, but the expense of the 1500-pound delivery wagon will vary. Not only this, it is impossible to measure the earnings of the machine because special and emergency delivery is represented by pleased and satisfied customers and the retention and expansion of patronage rather than a showing in actual dollars and cents.

The company has experienced a condition that is met with by many others—the difficulty of securing drivers who will handle ice, for many men are inclined to believe that if they drive a machine this is all the work that can reasonably be expected from them, while the drivers of the horses do this work unhesitatingly. If it is necessary to hire men to handle the ice and others to drive the trucks the economy of the machine is nullified by the additional expense.

Another problem that is receiving a great deal of attention is the kind of tires to use to afford the greatest economy. Tires have been purchased up to within a short time with a guaranteed mileage, and it is easy to compute tire cost a mile and a day, but the company has recently made a contract with a tire manufacturer that installs a set of shoes on a machine with no initial charge, and once a month a payment is made for the mileage the tires have been driven during the month. Just how this will work out is somewhat uncertain from the tire manufacturer's point of view, although such a contract is undoubtedly advantageous for the truck owner. As the trucks are loaded to capacity as much of the time as is possible, and for fully 50 per cent. of the distance driven, they are not easy on tires.

Work on the paving of the city streets is undoubtedly more destructive than on the highways, though this condition is generally reversed in winter.

KISSEL MANAGERS MEET.

Annual Gathering of the Branch and Factory Executives Held at Milwaukee.

The annual gathering of the branch managers and the factory executives of the Kissel Motor Car Company, recently held at Milwaukee, was an occasion of unusual interest for all present. The conference afforded opportunity for the company's officials to receive first hand information relative to the conditions wherever a branch establishment is located, and the heads of the branches gained precise knowledge as to policies and the mechanical details of the machines that are now being produced for the 1914 season. Practically all sections of the country were represented and the prevailing opinion was that the outlook was decidedly encouraging.

While most of the managers have been associated with the company for a considerable length of time, few had seen the large auxiliary plant at Milwaukee, which is to be devoted largely to the production of pleasure cars, while the wagons and trucks will be produced at the Hartford, Wis., factory. The works are now producing machines of all types and deliveries can be made immediately.

The Officials and Branch Managers of the Kissel Motor Car Company During the Annual Meeting at Milwaukee, Wis.

The meeting was decidedly interesting, there being thorough understanding of the Kissel selling and service policies, and there was confidence expressed that a large increase will be made in the production and sales. The accompanying illustration shows the following: Left to right, upper row—G. C. Frey, sales manager; J. M. Daggett, auditor; J. F. Lynch, manager St. Paul branch; P. J. Pollock, manager Chicago branch; Paul A. Rix, assistant sales manager; B. M. Linsley, manager Dallas branch; F. B. Hughes, manager Minneapolis branch; T. W. Warner, president Warner Manufacturing Company, Toledo, O. Middle row—Otto J. Koch, Koch Advertising Agency; H. B. Prudden, manager Boston branch; F. J. Edwards, manager Milwaukee branch; C. L. Curtis, manager Kansas City branch; E. Roger Stearns, manager Los Angeles branch; J. J. Kane, Jr., manager Philadelphia branch; H. S. Daniels, publicity manager. Lower row—George A. Kissel, president of the Kissel Motor Car Company; C. H. McCausland, manager New York branch; W. L. Kissel, treasurer of the Kissel Motor Car Company.

Several electric vehicles are now making demonstrations to department stores and manufacturers in Providence, R. I., which are intended to be of a length to give knowledge of actual working results.

SOME INTERESTING NEW DEVELOPMENTS.

A Motor Tractor That Drives with Reins Like a Horse---Single-Bottom Plow for Which Motorcycle Engine Supplies the Power---Orchard Tractor, Etc.

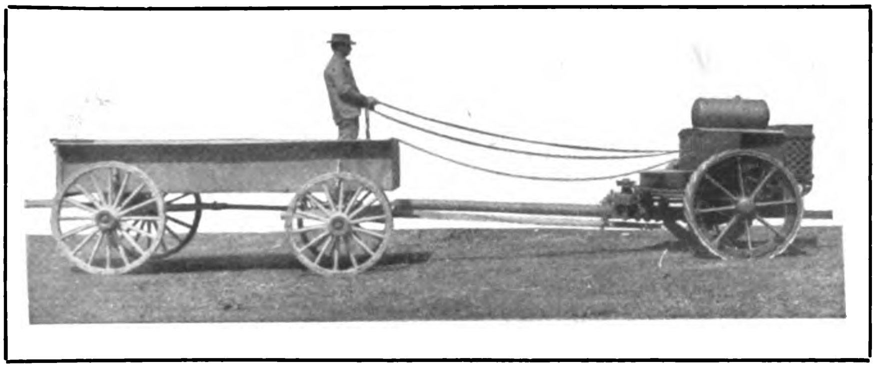
A MACHINE that is distinctive in appearance, at least, is the Detroit tractor, shown in an accompanying illustration. It is stated by the maker, the Detroit Tractor Company, 807 Scotten avenue, Detroit, to be the result of 15 years' experimentation, in which several thousand of dollars were expended in actual field work. For a number of years past machines of this same general type have been built and tested in farm work, until it is believed that the tractor placed in the market is thoroughly practical in every way. The final details of construction are said to have been worked out by an engineer who has devoted much of his life to the designing of machine tools for one of the largest concerns in that line in the world and who is now one of Detroit's foremost automobile engineers.

The object sought in this instance was a tractor that should be adaptable to many different kinds of work in order to take the place of horses and at the same time have the same utility on a small farm as the larger tractors have indicated on the large farms of the West. It is maintained that the Detroit tractor will pull any two-bottom sulky plow, roller, disc, drag, seeder, grain binder, corn harvester, mower, manure spreader and the wagon, and that the changes from one implement to another are easily made. It is also claimed to be a portable engine as well as a tractor, and it is pointed out that it should prove especially useful where the time of loading and unloading is important, as in the lumber yard for instance, and of course it is intended for use in haulage work on the farm, carrying products to market, etc.

As will be noted, the control is effected by means of reins, three of which are held to be all that is necessary, although a fourth is added to operate the brake when the tractor is to be used in hilly countries. Steering is accomplished by a pull on either the right or the left steering rein, which connects the engine by a special friction clutch to the steering gear. A very slight pull is said to be all that is necessary to make a complete turn. A pull on both steering reins simultaneously releases the main clutch in the engine flywheel, thus stopping the tractor. The third rein is used only to shift the gears from neutral to forward or back.

The main frame carrying the engine and gears is a semi-steel casting. The engine is made especially for the Detroit Tractor Company by the Continental Motor Manufacturing Company of Detroit. It is a four-cylinder, four-cycle, water-cooled unit of the L head type, with bore of 4.125 inches and stroke of 5.25, giving it a rating of 27.25 horsepower under the S. A. E. formula. Lubrication is by a positive plunger pump system with constant oil level, all enclosed within the crankcase. Cooling is aided by a radiator of special design, of the vertical fin tube type. Ignition is by Bosch high-tension magneto. The carburetor is designed to vaporize gasoline, kerosene, distillate and low grade fuel oils, although gasoline is used for starting. The capacity of the fuel tank is 30 gallons.

The clutch is a 16-inch leather faced cone, and power is transmitted through direct gears, two spur gear reductions being all that are required between the crankshaft and the driving wheels. A separate oiling system is utilized for the bearings and gears, when the tractor is in motion. The main axle is solid, of 2.5-inch cold rolled steel, and the driving wheels are made with wide flat grouters, which are held not to injure the finest road surface. For field work, detachable cones are furnished, which gives the wheels the proper tractive power in soft ground. Extension rims are supplied when desired. The speed of the tractor is given as from 2.5 to four miles an hour.

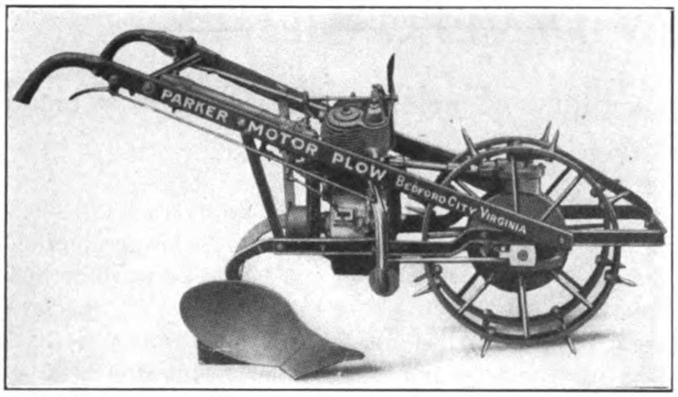


The Detroit Tractor, Steered by Reins, Attached to Farm Wagon for Use on Road.

PARKER MOTOR PLOW.

A Novel Application of the Gasoline Engine to Agricultural Purposes.

Some six months ago reference was made in these columns to a motor operated plow which had but recently made its appearance in England. The machine was designed for use by orchardists and was regarded as a thoroughly practical invention. It appears that long before the British product was placed in the market Joseph N. Parker of Bedford City, Va., who was at that time teaching school, was experimenting with an ordinary plow to which he attached a motorcycle engine. The result of that experimentation has been the organization of the Parker Motor Plow Company of that city, in which the Parker brothers, Joseph N., William A. and Don E., are engaged in the



Parker Motor Plow Utilizes Twin Cylinder Motorcycle Engine.

production of the Parker motor plow shown herewith.

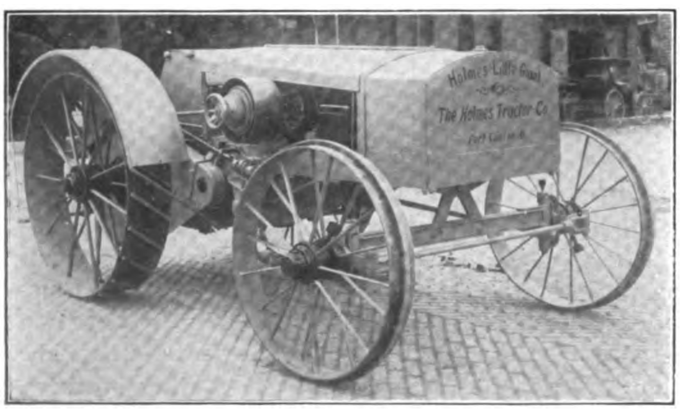
The chief feature of the invention lies in the method of control, the operator walking behind the plow, or harrow, cultivator, wheel hoe, seeder, etc., as when horses are employed. In addition, fittings are supplied with which it is possible to utilize the motor as a stationary engine. The whole equipment is light and easily managed. The control mechanism is located on the plow handle so that it is possible instantly to throw the motor out of engagement, lift the machine over any obstruction and as readily place it in operation again.

The motor is a two-cylinder, air-cooled, nine horsepower motorcycle type and is installed midway between the frame side members over the working attachment. Ignition is by Bosch magneto. This engine drives, by shaft and gear reduction, two spiked wheels. It is maintained that the suction created by the plow holds these driving wheels to the ground and that the spikes prevent them from slipping, thereby enabling the machine to work equally well in sod, soft ground, loam or sand.

HOLMES LITTLE GIANT.

A Tractor Designed to Do the Work of Four Horses on the Small Farm.

Another tractor that is designed for the orchardist, the man with a small farm or anyone who has use for a machine that will do the work of four horses, is the Little Giant, made by the Holmes Tractor Company, successor to the Holmes Manufacturing Company, Port Clinton, O. This concern has been in the manufacturing business for a number of years and in the production of the Little Giant, the use of jigs, templates and micrometer measurements is held to make for interchangeability of parts and easy replacement whenever necessary.



The Holmes Little Giant 12 Horsepower Tractor.

The motor is a Dice two-cylinder, opposed unit, rated at 12 horsepower. The bore of the cylinders is 5.5 inches and the stroke five. Cooling is by water, the capacity of the system being 40 gallons. Lubrication is by mechanical oiler and splash. Jump spark ignition is employed, utilizing batteries and coil. The Schebler carburetor is supplied from a tank of 25 gallons capacity, and the motor is governed to a predetermined speed.

The planetary type of transmission is used, affording two speeds forward and reverse. The low speed is utilized only for starting and turning in close quarters, it being maintained that the machine can be turned in a 24-foot circle. The high, or working speed, is rated at from 1.5 to 1.75 miles an hour. Drive is taken from the transmission to the differential gear by

The Holmes Little Giant Engaged in Orchard Work.

a jackshaft, the final drive being by a chain.

The frame is of steel channel, braced and hot riveted at the corners and cross members. The rear end of the frame, which carries the greater portion of the weight, is spring mounted. The front axle is fitted with the automobile type of steering knuckles and is pivoted at the centre to allow for unevenness of the ground without twisting the frame. The front wheels are 36 inches in diameter with five-inch face, and the rear members 78 inches diameter with 10-inch face. The height over all is 54 inches, width six feet and length 11 feet six inches. The weight, complete, is 4060 pounds.

MOTOKART PARCEL CAR.

Tarrytown Motor Car Company Announces Its First Light Delivery Model.

Interest in the product of the Tarrytown Motor Car Company, Inc., Tarrytown, N. Y., has been awakened because of the wide acquaintance of President A.

Motokart Parcel Car Made by Tarrytown Motor Car Company.

R. Gormully, who was until recently connected with the Maxwell line in the United States Motor Company. The company is now ready to announce its first model, which is illustrated herewith.

The power unit is a two-cylinder, water-cooled motor with bore of 3.625 inches and stroke of four. Cooling is by the thermo-syphon system. The transmission of power is through a friction drive with its unlimited number of speeds, which is expected to make a decided appeal, inasmuch as the vehicle is designed for service where traffic is more or less congested. For this reason, also, the dimensions have been kept down to a minimum, the wheelbase being 65 inches and the tread 44. Suspension is by semi-elliptic springs and wire wheels are employed. The carrying capacity is placed at 400 pounds, exclusive of the driver. The dimensions of the box are 48 inches length, 35 inches height and 32 inches width.

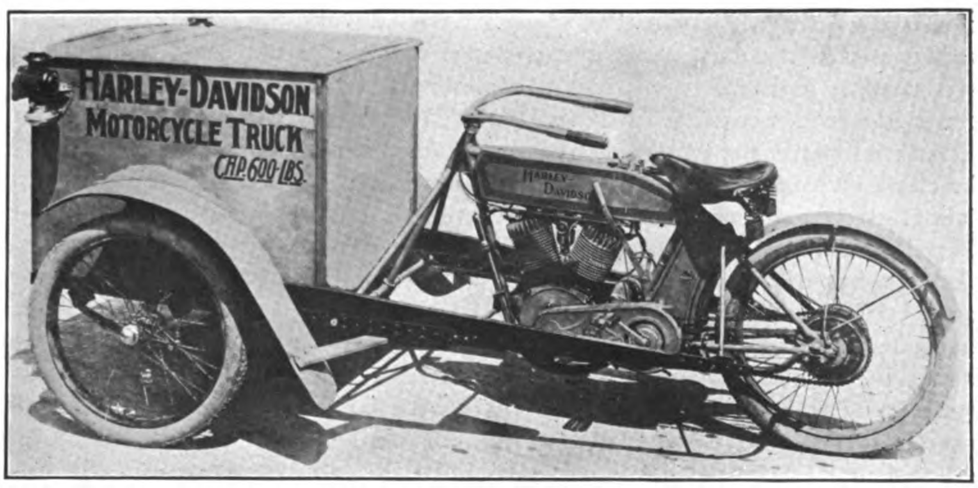
HARLEY-DAVIDSON TRICAR.

Motorcycle Manufacturer Produces Parcel Car Rated at 600 Pounds Capacity.

While a number of the motorcycle manufacturers have produced parcel cars or tricars designed for parcel delivery, the Harley-Davidson Motor Company, Milwaukee, Wis., claims to have carried the matter a step further in its motorcycle truck, so-called, which is rated at 600 pounds capacity. The wheelbase is 76 inches and the tread standard, 56, and several different kinds of bodies are fitted. The standard design, shown in the accompanying illustration, has a width of two feet 10 inches, length of three feet six inches and height of two feet four inches.

Except for the additional strength of the chassis, the construction throughout follows closely that which has proven so successful in the regution Harley-Davidson motorcycle. Among the features, and one which is held to be of decided importance in a vehicle of this character, is the use of the Harley-Davidson two-speed gear, which gives a ratio of 5:1 on high speeds and 10:1 on the low. Another feature lies in the fact that it can be started from the seat without raising the rear wheel from the ground, the engine being started by depressing either pedal, this action imparting motion to the countershaft. Transmission is through the well known free wheel control, used on this make of machine.

Statistics of the manufacture of automobiles, including bodies and parts in the United States for the year 1909 will shortly be issued by the census bureau of the Department of Commerce. This will show that there were 743 different concerns in the classification, but of these only 263 produced complete automobiles as the chief product of value, although they employed more than two-thirds of the average number of wage earners engaged in the entire industry. The total value of products in the year 1909 for the two branches of the industry was $249,202,075, of which $193,023,108 was the valuation of the production of the companies engaged principally in the manufacture of automobiles, and $55,378,967 was the value of the products of the concerns producing principally bodies and parts. The total value of the complete machines manufactured was $164,269,324. There were 126,593 automobiles built in 1909, and all but 23 were built in establishments reporting automobiles as the product of chief value. Michigan was the leading state in the industry with reference to total number and total value of vehicles built. Indiana was second and Ohio third. Of the 743 companies making report 56 reported production valued at more than $1,000,000. The product having the greatest value was the touring car, there being 76,114, valued at $113,403,188, turned out. The report shows that there were, in 1909, 265 establishments employing 58,142 persons (of whom 51,294 were wage earners), using capital of $134,592,965, and paying wages reaching a total of $33,180,474.



Harley-Davidson Parcel Delivery Car, Termed a Motorcycle Truck by Its Maker.

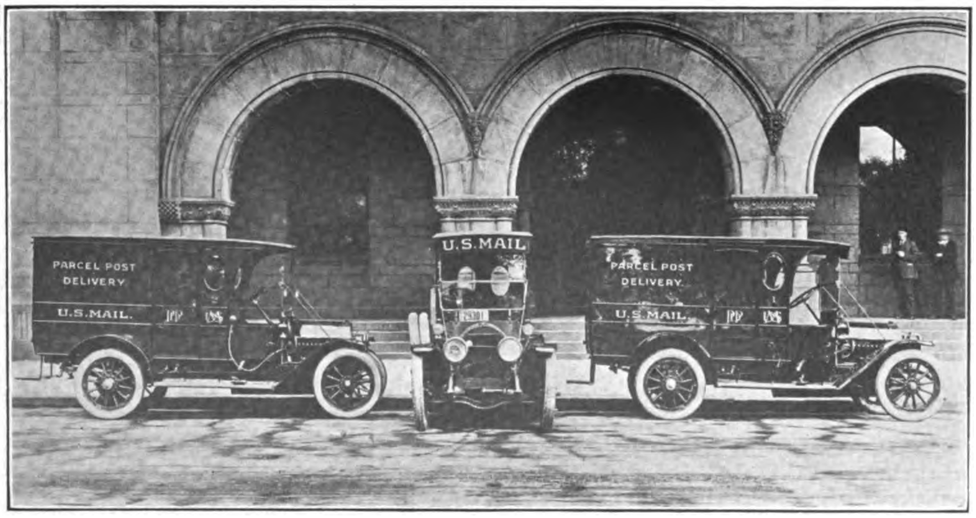
STREET BUILDING WITH TRUCKS.

City of Detroit Utilizes Five-Ton Machines for Hauling Asphalt for Paving.

The department of public works of the city of Detroit, Mich., after a trial of approximately two months, has purchased two five-ton G. M. C. trucks equipped with dumping bodies for use in hauling asphalt that is used for street paving construction and repair. Until May horses had always been used for this work, but the head of the department decided to experiment with motor trucks. Detroit is fairly level and it covers a large area. Many of the streets are asphalted, and because of the large mileage of this paving and the need of maintaining as well as constructing the city has established a plant where the bitumen is heated and prepared for laying.

The asphalt is mixed with material in the proportions for application, and it is carried heated to the place of construction. Asphalt can be handled with dumping bodies provided it is not allowed to cool too low, and as it cannot be heated above a certain temperature it is necessary to handle it as rapidly as possible after loading. When the machines were first tried they were used against horses and in whatever work was undertaken it was the experience that they were cheaper and more economical than animals. This fact influenced the sale.

An example of the work was hauling material from the city's plant at 18th street and Michigan avenue to Palmer street and Second avenue, a distance of about 2.5 miles. The trucks made nine round trips, covering 45 miles, hauling five-ton loads, at a cost of approximately $7.50. This was equivalent to hauling 112.5 tons one mile daily. Besides this there was a great saving in time. To have the asphalt ready for the workmen at 8 in the morning the drivers of the horse wagons reported at the plant at 3 in the morning and left at 4, but the trucks did not report until 6:30 and left at 7:10. By the time the horse carts were ready to return the trucks had reached the first stop at least. The trucks made three times as many trips as the horses and carried twice as much tonnage each load.



Three KisselKar Delivery Wagons Utilized in the Parcel Post Delivery by the St. Paul, Minn., Postoffice.

THE ENTZ ENGINE STARTER.

Electric System Now Produced Suited for Truck and Delivery Wagon Equipment.

The Dyneto Electric Company, Syracuse, N. Y., maker of the Entz electric engine starter and lighting system, is now producing an equipment that is especially suited for service on delivery wagons and trucks. The Entz system consists of a motor-generator and a battery with wiring connection that may be adapted for use on practically any vehicle, the generator serving as a motor to start the engine and then furnishing current for the storage battery from which the energy for lighting is supplied. The motor-generator is mounted on the engine case and is driven by a silent chain, and the battery is installed beneath the floorboards, the control being a switch located on the dash. The combination of starting the motor and lighting is accomplished with but one moving part, this being the armature of the motor-generator. There are practically no automatic controls, the battery being floated on the line and the motor is changed to a generator and back to a motor as the electrical pressure rises or falls above or below that of the battery.

The motor-generator gives its full output when operating as a motor or a generator and the speed is so low that it is permanently geared to the engine at a low gear ratio, and is equally efficient as a motor for starting the engine or a generator in charging the battery and supplying the lights. It generates full voltage at such low speed that no battery controller is necessary to produce a lower voltage for charging than is required for starting. Because of the armature windings it is a generator above a definite speed and is a motor at less than that speed. The electrical connection between the battery and the motor-generator is made with a knife-edge switch located on the dash. Closing this switch, if the motor-generator is stationary, causes the current to pass to it from the battery, starting the engine. After the engine is running when the voltage pressure exceeds that of the battery charging is begun and continued at a definite, governed rate. The construction is designed for installation with practically any form of standard motor, and the starter may be fitted by any practical mechanic without special work, so the cost need not be excessive.

NEW CHASSIS CONSTRUCTION DETAILS.

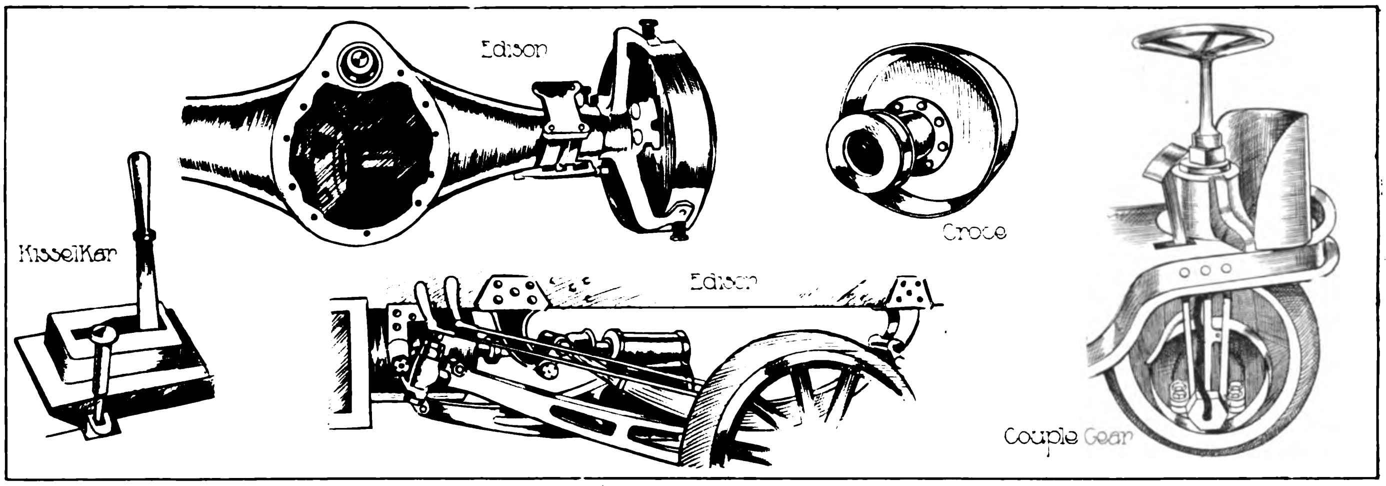
Characteristics of the Eldridge Single Front-Wheel Driven Cart—Features of the Buffalo and Edison Machines and Other of the More Recent Productions.

THE designer who can eliminate a part from a group of chassis components and preserve all the other qualities desired has accomplished what ought to be the chief purpose of every motor vehicle engineer, because simplicity means as a rule greater efficiency, endurance and economy, which may be regarded as the three fundamentals of motor conveyance design. There are, of course, limitations so long as it is believed necessary to preserve principles that were followed mainly because they were convenient in the construction of horse conveyances. In designing, however, there are two factors that usually receive consideration, the one is construction that will endure for practically the life of the machine, and the other is ease of replacement of what will necessarily wear proportionately to the service.

Standardization has generally been with reference to detail, and frequently with a purpose of insuring desired. Because of this character of production it is not possible for the assembled machine to have the individuality that might be found in the vehicle specially designed and built, but these have the merit of being somewhat cheaper, and, assumedly, uniformity of quality so far as workmanship and material are concerned that might not be found in the special design.

Not only this, there are few who realize how expensive a comparatively trifling change in a design may be, which applies particularly to the gasoline vehicle. The electric machine design development is directed more generally toward the elimination of frictional losses and this means high grade material and careful workmanship. There has not as yet been special production of the elements of the electric chassis aside from the motors and batteries.

Probably one of the most interesting creations of the year is the single-wheel driven cart built by the



The Differential Lock of the KisselKar 2500-Pound Chassis; the Rear Axle of the Edison 3000-Pound Wagon; the Motor, Radius Rod, Spring and Torque Arm Assembly of the Edison 3000-Pound Wagon; the Croce Clutch and the Single Front-Wheel Drive of the Eldridge Two-Ton Cart.

interchangeability, but this has not been applied to the principal elements. There is little probability that engineers will agree as to the forms, dimensions and materials, and each seeks to work out his own ideas so far as this can be done, but where parts are designed with a view to manufacturing them for use in practically any machine the necessity of standardizing production is apparent. This may be applied to what is known as the assembled vehicles, where different groups or assemblies are purchased and combined, in some instances only labor being necessary to fit these and produce the finished machine.

It is now practical for the company intending to build a wagon or truck to buy every part and to have these delivered in the original form produced or fitted for assembling, and some very large concerns now manufacture parts that may be adapted, or will furnish, at somewhat increased prices, whatever may be

Eldridge Manufacturing Company, Boston, Mass., which has a capacity of two tons and is intended to do the work for which the horse and cart are now used. Having a radius of movement of approximately 25 miles and being practical for service in space where no animal could be worked, with sufficient power to climb moderate grades when loaded, this machine is regarded as being a distinct advance because it is economical in first cost and its operating expense corresponds very well to the upkeep and maintenance of the animal outfit it is intended to replace. The accompanying drawing gives a clear idea of the construction. The footboard of the "necked" forward end of the chassis frame is a steel plate that supports the bracket or base through which extends the heavy fork that carries the driving wheel, and the fork column is retained in this base by the nut or collar at the top.

There are no springs for the forward wheel, the

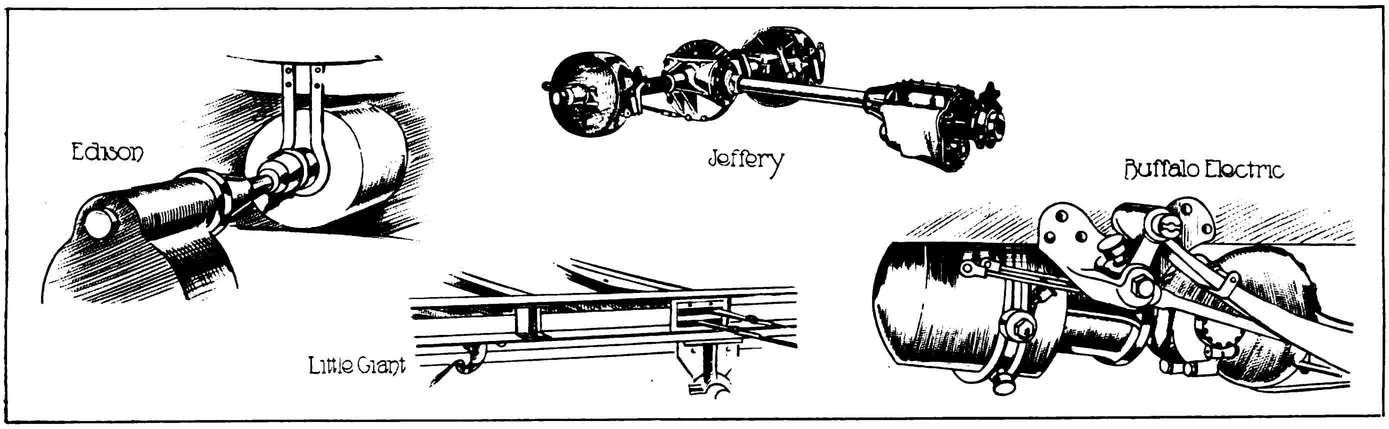
collar above the fork bearing directly against the lower side of the plate. The road shock is absorbed by the large wheel tire, and the driver is protected by a well sprung seat. The fork is a heavy steel forging, the arms being ribbed to insure strength, and in the ends of the arms the axle stubs are fixed. It was necessary to have a special design of wheel, for both wheel flanges contain axle bearings, and both axle stubs are of equal length. These axle stubs are integral with the motor frame, but in the standard Couple-Gear construction the short stub is retained in the outer wheel flange and is covered with a cap. The special wheel has flanges that are practically identical and both have the same bearing on the axle stubs. The weight of the vehicle is carried by the long inner stub with the regular Couple-Gear wheel, but such stress is eliminated, or at least equally distributed on both axle stubs.

Each wheel flange carries a large brake drum and the fork ends are used to support the brake shafts on which the contracting shoes operate, and wire cables permit the free turning of the wheel. It may be swung at an angle of 90 degrees and the cart may be turned in its length. The construction is such that by blocking the chassis frame to its normal height the wheel may be quickly removed should this be necessary, and by the removal of a flange the motor may be exposed for work, inspection being possible through large hand-holes.

There will probably be supposition that the vibration will be excessive as the chassis is carried on a dead rear axle, and the only shock absorbing effect for the entire chassis is the solid rubber tire of the front wheel. The rear wheels are shod with steel tires and the wheels are very large, this insuring a comparatively small current output to obtain tractive effort. As five miles an hour is maximum speed the road shocks will not be as severe as were the machine faster, and the construction so far as the wheel is concerned has been amply tested.

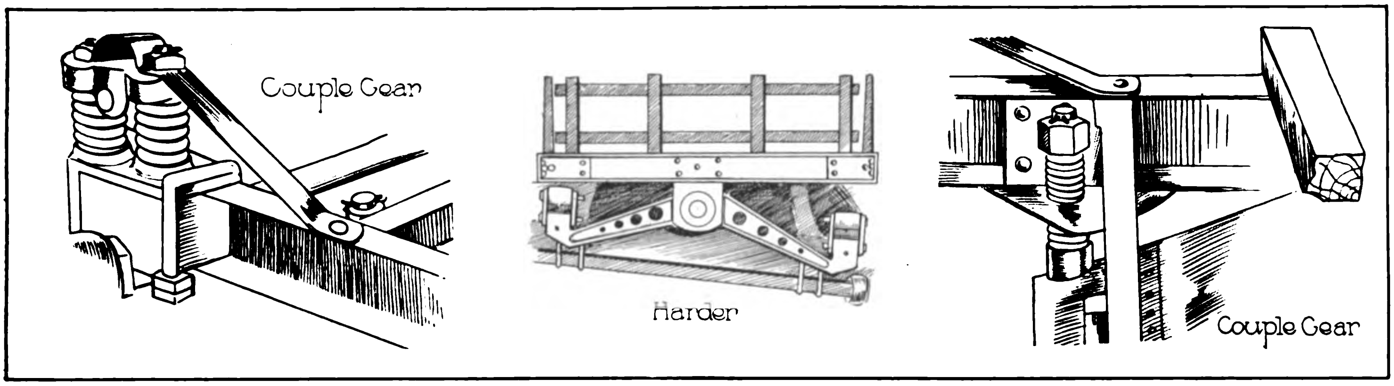
Reference to another drawing of the series that illustrates this article will show the ingenious manner in which the battery is protected against shock and jar, for being a lead type and composed of hard rubber jars a severe jolt might break a cell or one of the straps connecting the cells. The battery box is suspended between the axles and there is a frame below the box to prevent damage should there be breakage of the connections with the chassis. The chassis frame is channel section steel and where the cross members are riveted to the sides are reinforcements in the form of heavy gussets. A large rod extends upward at the corners of the battery box and this is threaded at the upper end. The rods are carried through the gussets and helical springs are placed above and below the plate, the desired tension being secured through a nut holding a collar at the top of each rod. Thus every movement of the battery box is spring resisted and the battery is as well protected as though the frame were suspended in the usual manner.

It is not to be supposed that the loads to be carried will be of such a character that breakage may be feared, but to prevent the noise incident to the jar of a metal body an ingenious device has been developed. The body is supported by a bar or axle beneath it that strengthens the construction, and the ends of this bar are carried in fittings that are centred between two heavy helical springs. These springs are maintained in position by a strap that is carried forward and bolted to the chassis frame, and this is tempered to have elasticity. The springs are seated on blocks bolted to the chassis frame, and the blocks are fitted above the rear axle, stiffening the channel section and preventing buckling under load. When loaded the springs are depressed and load is practically dead, but when light the springs support the body and minimize the rattle and the effect of jar and jolt.



The Motor and Worm Drive of the Edison 1500-Pound Delivery Wagon; the Unit Rear Axle, Driving Shaft and Transmission Gearset of the Jeffery Delivery Wagon; the Truss Frame of the Little Giant Wagons and the Motor, Torque Arm, Radius Rod and Spring Assembly of the Buffalo Wagon.

A Couple-Gear tractor built for a lumber firm is intended to be used with two batteries, the exchange being made at noon. The purposes of this concern could be best served by the removal of the battery and box, instead of removing the trays of cells or a tray fitting into the battery box. The machine is a tractor and the battery is carried above the chassis frame. The edges of the bottom of the box drop below the tops of the frame side members sufficiently to prevent transverse movement and fittings bolted to either end of the swinging gate of the box when secured by a latch prevent the box sliding on the chassis. The device is simple and comparatively inexpensive, while it meets the requirements admirably in service.



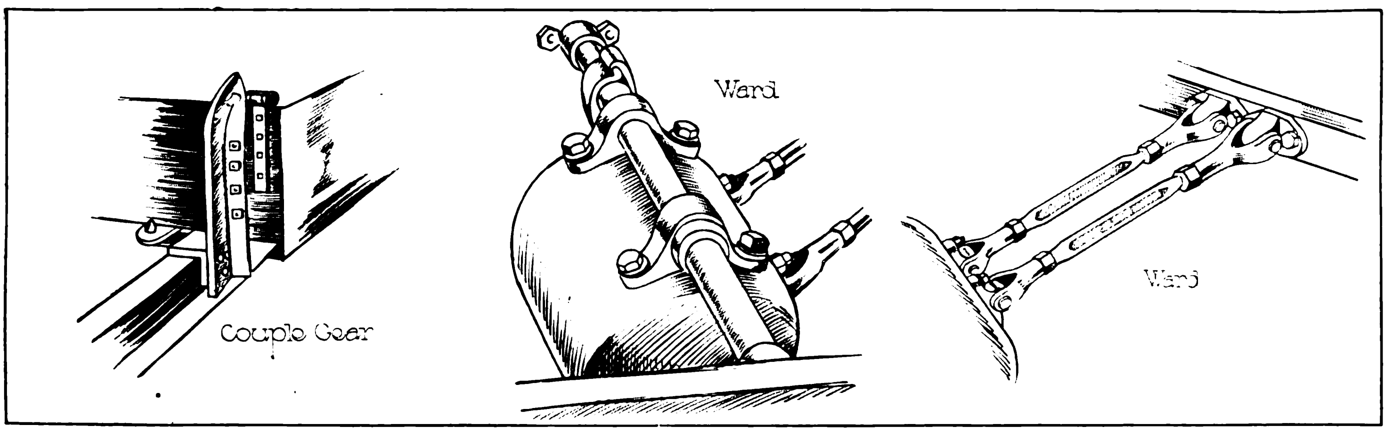
The Helical Spring Body Suspension of the Eldridge Two-Ton Cart, the Yoke Connected Rear Springs of the Harder Truck and the Battery Box Support of the Eldridge Cart.

The Edison Electric Vehicle Company of America builds two machines that have received some public attention, these being of 1500 and 3000 pounds capacity. Both are noticeable from the fact they are worm driven, and it is necessary that these be fitted with specially built axles and torque arms. The smaller machine has no radius rods and is driven through the springs. The motor in this is supported by a U shaped steel strap at the front and rear, and there is one universal joint in the driving shaft, the reduction being through the worm wheel and worm. The shape of the differential housing is unusual and seemingly it is unnecessarily large, but it is a clean casting and is easily accessible. The differential housing carries the rear end of a torque arm that is coupled to a frame cross member beside the motor.

The rear axle of the 3000-pound Edison delivery wagon is a special production and seemingly it is extremely heavy, the cast steel housing having a large diameter to take the worm wheel, while the worm is carried in a casing reached from the front side of the shell. The driving shafts are mounted on bearings of extremely large diameter. With this machine semi-elliptical springs are used and the drive is through radius rods, but there is a large torque arm of a skeleton type extending from the rear axle housing to a frame cross member. In this machine the radius rods are a skeleton type, and have a peculiar coupling at the forward end, a construction that is well shown in the drawing.

The latest type of Ward electric machines uses motors that are suspended transversely in the frame, and these are hung from a large rod on which are brackets that are bolted to the frame of the motor. This construction is not unusual, but because of the drive by silent chain from the motor to the jackshaft it is necessary to have means to preserve its alignment. This is done by the use of two radius rods that extend from the motor frame, being connected about at the line of the armature shaft, to the rear cross member of the chassis frame. The radius rods consist of two forked or yoked ends that are tapped and threaded with right and left threads, and centre sections that screw into these, having a turnbuckle effect, check nuts insuring permanency of position. The yoke ends are securely bolted to lugs on the motor housing and the frame. The double radius rod of the motor is intended to insure against any possibility of twist of the motor, and this adjustment compensates for the wear of the reduction chain from the motor to the jackshaft. Generally one radius rod is regarded as sufficient. Incidentally these rods are very accessible and adjustment can be made with ease.

The motor of the Buffalo electric delivery wagons is constructed with a strap encircling it that carries trunnions at either side. These trunnions are fitted to bearings in a frame that is mounted on a frame cross member so that the motor is pivoted and is free to move on these bearings. The driving shaft is coupled to the armature shaft of the motor, and at the other end engages with a reduction gear from which the driving influence is through a pinion meshing with

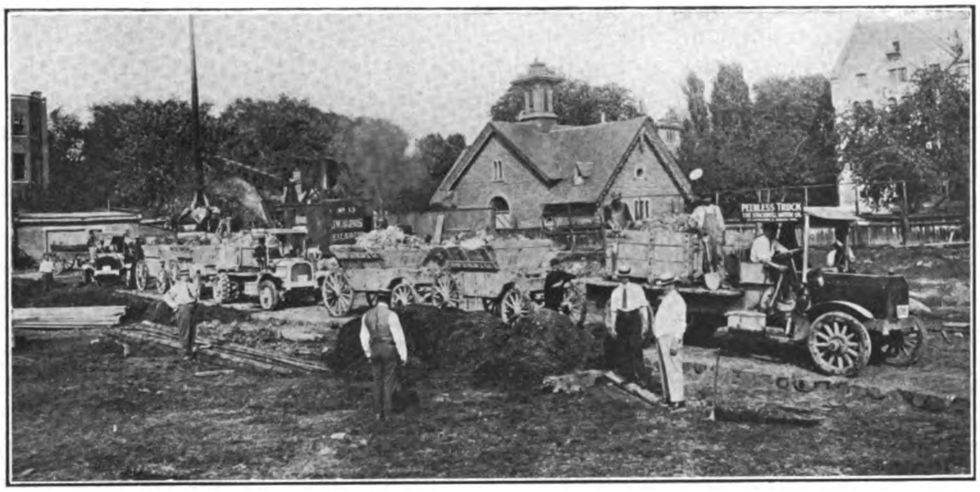


The Battery Box Fitting of the Couple-Gear Tractor, the Motor Suspension of the Ward Electric Vehicles and the Double Motor Radius Rods of the Ward Machines.

the bevel gear of the differential. The semi-elliptic springs are shackled at either end and the drive is through radius rods that are coupled with the spring hangers, this making an extremely simple and efficient combination fitting.

The rear axle, driving shaft and transmission gear-set of the Jeffery 1500-pound delivery wagon is assembled as a unit, this obviating the need of universal joints in the driving shaft, and the forward end of the transmission shaft is coupled to the clutch shaft, the unit having a vertical movement at the rear end from a pivoted connection with a frame cross member.

What is probably the only truss type of frame in a motor vehicle is that of the Little Giant delivery wagons, the side members being formed of steel angles with connecting members at intervals between them the entire length of the chassis. The construction is maintained to afford unusually light weight and to have extreme strength. The space between the upper and lower frame members permits the installation of guides for the brake equalizers, these having especially advantageous location without loss of strength.



A Peerless Truck and Two Trailers Used with Much Success in Construction Work by a Montreal, P. Q., Contractor.

The Harder truck is suspended at the rear on what is practically a platform construction, but instead of the usual cross spring a skeleton yoke is used. This yoke is a steel casting and it is mounted at the centre on a pivot centred in a block bolted to the chassis frame. The ends of the yoke are formed to take the lower bolts of the spring shackles and normally the chassis stands even. When one wheel is raised the yoke swings on the pivot and one spring end is raised and the other deflected, there being no additional stress upon either, while the weight is equally distributed upon them. The result is maintained to be more satisfactory than when a stationary spring is used.

The clutch of the Croce delivery wagon and truck chassis is a cone type that has a sleeve bolted to it. At the rear end of the sleeve are two collars, between which is placed a fork which actuates the clutch. Contained in the sleeve and surrounding the shaft is the clutch spring, and this is adjustable so that any desired pressure may be obtained. The advantage of the design is maintained to be in that it insures freedom from wear and affords ease of adjustment.

One of the features of the KisselKar 2500-pound delivery wagon chassis is the differential lock, which is controlled by a short lever that is moved in a heavy metal fitting secured to the footboard close to the driver's seat. The lever may be moved by the hand or the foot and it may be released by depressing a plunger that is located beside it.

TRUCKS SAVED 55 CENTS A TON.

Experiment in Trailer Haulage Sells Seven Large Peerless Machines to Contractor.

While trucks are not designed to carry more than a given load there is no doubt of the power that may be obtained in useful work, provided, of course, that speed is not the only object sought. Experiments have been made with trucks hauling trailers that have not been productive of satisfactory results, largely because they have not been continued over a sufficient period. Generally trials have been for a short time and under conditions that cannot be regarded as those met with in the average of work.

A Montreal, P. Q., contracting firm recently undertook to test the practical possibilities of trucks with trailers in work in that city, using one and two trailers, these being animal wagons that had been adapted for the service and which were constructed to be discharged quickly. The trains are made up with two trailers, carrying nine tons, 2.5 tons on the truck and 3.25 tons on each wagon, and it was found that the truck could haul the trailers over comparatively rough ground and in soft roads at a satisfactory speed—at least, fast enough to be very economical. The cost of moving excavated material was with the loads described reduced from $1.50 to 95 cents, the comparison, of course, being made with horse haulage. So satisfactory was the trial that the company bought seven four and five-ton trucks and will use them with trailers in excavation work whenever possible, and in other haulage wherever practical.

Several Koehler commercial cars, made by the H. J. Koehler S. G. Company, New York City, have been put to extremely hard tests. The Clinton Hill Lumber Company of Newark, N. J., had a special body built for its machine which enables it to carry long lengths of lumber with the use of a two-wheel trailer. The loads have run into several tons and the car has been in service for nearly a year. A Boston milk dealer has used his machine about eight months and daily carries 2800 pounds of milk over some very rough roads.

TRUCKS FROM THE CONTRACTORS' VIEWPOINT.

THE Motor Truck Club of New York City is one of the most active and energetic organizations identified with motor vehicle transportation. It is composed of men who are associated with many of the companies now producing wagons and trucks, and of those who are engaged in haulage. The club has monthly meetings at which subjects of importance are considered and from time to time men prominent in concerns and associations requiring large transporting equipment are invited to present the "other fellow's view." There is no doubt that the exchange of opinions and experience is distinctly beneficial.

At the meeting of the club the evening of June 25 a paper was read by C. A. Crane, secretary of the General Contractors' Association of New York City, and as this was prepared from the viewpoint of the contractor solely it was of unusual interest. The paper was based upon the supposition that it is necessary for the motor truck salesman to prove the value of the machine to the prospect, and for the manufacturer's service department to work out the problems and to overcome the adverse conditions, it being maintained that this was a custom with manufacturers in other lines with whom the contractors came in contact. The paper follows:

It used to be said that when a man had been a failure at everything else he became an insurance agent. Don't think for a minute that I am so grossly unmindful of your hospitality as to make any invidious comparisons, but countless noble masterpieces of fiction were lost to the world when some of the motor salesmen I have met entered the automobile business! And when we stop to consider the marvelous development of the business—all within the last 15 years—you must admit that it offered an elegant field for the romancer—which was not neglected. I have sometimes given a salesman credit for really believing what he said about a car as long as he was selling that particular make, and I think I am only sharing the general belief in stating that the greatest trouble the salesman had was in filling, rather than getting, orders.

Transportation of all kinds has three stages—the romantic, the useful, the indispensable. Railroads and steamships have demonstrated this. The aeroplane is now in the romantic stage, the bicycle reached the useful, and the motor truck has rendered the automobile indispensable in many lines of business.

But the clever salesman is not content—he knows in his own heart he isn't clever when he sells to a man who wants to buy. It's only when he can sell to the unwilling purchaser that he is entitled to medals, and that's what he is up against—an unwilling purchaser—when he attempts to sell a motor truck to a contractor. You've got to show the contractor, and from my limited knowledge with the contracting business, I'm bound to say you haven't done it.

The contracting business has more peculiar and varying conditions than perhaps any other. There were never any two contracting jobs precisely alike, any more than, as they tell us, there are any two thumb prints precisely alike.

Now I'm speaking of contracting from the standpoint of the contractor—not the material man—for I notice in the announcements published in the motor truck publications that the lists of contractors using this or that motor truck class material men as contractors—and in those lists I have found that of those whom I know, 90 per cent. are material men and not contractors, and I assume that percentage is not far off on the entire list.

The considerations which lead a material man to purchase a motor truck are as different from those which would appeal to a contractor, as are their two classes of business. The material man is governed almost solely by competition; if he can save on haulage he can undersell a competitor. If he doesn't keep abreast of his up-to-date, cost shaving competitors, he wouldn't hold his business, and he must be alive to that fact every minute. With a contractor it is somewhat different—not that competition isn't just as keen—but once he gets the job, the competition ceases for that work. All that remains is to carry out the work as he planned it in preparing his bid, and with the plant he had in mind, and the owner, the party of the first part, pays the price.

Now the bid includes a profit—or the contractor thinks it does when he bids—and barring mistakes or accidents, he will make that profit. You come to him and suggest motor trucks instead of horses. He has figured on using horses and that figure is in his estimate. He doesn't know what a motor truck will do, he isn't in a position to experiment for his contract carries a penalty for delays and overtime. Here's a situation for the clever salesman to convince a man who has a sure thing and nothing to gain but a little more profit, to abandon his plan and perhaps lose all his profit. The superiority of the motor truck over horses is not to be denied by the material man, the brewer, the delivery trades, but to a contractor, live stock is live stock and machinery is scrap.

There is always a good market for a horse. This is one great advantage the horse has over the motor truck. Another is the availability of the horse in many situations where a motor is impracticable. Therefore the contractor must rely to a large extent on horses, and the two methods of power are not adaptable to good team work, as we might call it. Another argument advanced against horses that isn't weighty with contractors is that their use is regulated by weather conditions, and a motor truck is not. If the weather were such that the work were shut down, the motor truck would be idle also, and if it were possible to turn the truck into hauling material, the same is done with horses.

Understand me, I do not contend that the motor truck is not superior to horses for purely delivery purposes, but transportation of material is not the controlling factor in contracting; it is only in a comparatively small percentage of jobs that it is even a considerable factor. The main thing is the disposal and placement of excavated materials; of concrete and the various fabrications that enter into the completed structure. Here in New York in the city tunnel and subway work there are some notable instances of the successful use of motor trucks in hauling away tunnel muck, but it must be remembered that the conditions were ideal for the use of trucks—smooth pavements, and in most successful instances, dumps which were used solely by the motor trucks which permitted of special dumping machinery. In the downtown districts, where the only available dumps are public, they are impracticable for motors because of the long time lost waiting in line with horse drawn vehicles.

I might go on indefinitely citing conditions in the contracting business which operate against a more extensive use of motor trucks by contractors, but I won't tax your good nature. You may have gathered that I am unalterably opposed to motor trucks, but on the contrary, I am a firm believer in them, and I think the reason why more are not used as adjuncts in the contracting field may be ascribed to the methods adopted or the methods omitted by the salesmen and the manufacturer in dealing with contractors.

I am firmly of the opinion that there is a great future for motor trucks in this field, but you are not reaching it by selling a man a machine for $5000 or $6000 and then leaving him alone to experiment with it. It's up to you to do the experimenting—the educating—not the purchaser. For every instance of which I know where a motor truck has given satisfaction I can cite another where it has been a failure—and I am satisfied that it wasn't altogether the truck's fault.

The machinery men who handle contractors' plant follow up a sale and find out if the machine is being properly used—if the machine is the best suited to the particular conditions—and they make it their business to see that it gives satisfaction. They maintain corps of experts who can advise on the best methods of planting a job and handling it—who can design special machinery for unusual conditions. They will install a new device, subject to approval before purchase—and the same methods are necessary on your part. The contractor's problems which can be solved by the motor truck must be worked out by you. You are the people to take the chance—not the contractor—and when the burden of proof is on your shoulders, the incentive will be there to deliver the proof.

Cost data are not convincing. As a matter of fact I am very skeptical of the cost purporting to come from contractors and published in the motor journals. If a contractor has a good thing he isn't going to let the public and his competitors know how good it is, and if he is stung he isn't going to sing about it either. Cost tables won't sell motor trucks, but a plausible idea on their feasibility for handling certain work will interest a contractor. There are a thousand and one details to be worked out. So far only one seems to have been considered—the sale. When some of the others receive your attention the motor truck will be in a fair way to become an indispensable item in the contractor's outfit.

It formerly required five horses to drag a three-ton load up a steep hill leading to the I. Renaud Company's wholesale grocery warehouses at Fall River, Mass. A KisselKar truck, made by the Kissel Motor Car Company, Hartford, Wis., rated at three tons, now does this work at an operating cost of $1.25 a day, and the labor and time necessary have been greatly lessened. This truck, in use since Sept. 1, 1912, has had practically no repairs, while the cost of maintenance has been less than that of one horse.

The MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.

SUBSCRIPTIONS:

The United States and Mexico, the year $1 in advance; Canada and Foreign Countries in Postal Union, the year, $2 in advance. Fifteen cents the copy.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

LOAD HANDLING FACILITIES.

Probably no greater object lesson as to the necessity of facilities for quick loading can be found than in the majority of the department stores, especially in the large cities. Many of these have admirable equipment for quickly collecting and handling the packages in the shipping rooms, have the vehicles with which they may be rapidly transported between the store and the route, and the trained employees necessary for economic results, but with rare exceptions these stores load their wagons on sidewalks that are frequently crowded with traffic and where the packages must be sorted for the routes and arranged for convenient distribution. This means that the goods must be carried from the elevators along the walks to the wagons and a good deal of time lost in sorting, which includes the time of the vehicles and of the drivers and helpers. Not only this, the shipping is so conducted that the wagons start at approximately the same time, which means loading congestion and the greater number using the crowded elevators and sidewalks, when it would seem practical to load in convenient relays and have as few men and vehicles at the store as were possible.

From an ideal point of view a large loading platform or room would be much the better and far more economical, for if these were of sufficient proportions they could be used for receiving purposes and, even if space that might be used for sales departments were encroached upon, it is practical to attract customers to any part of a store with adequate elevator service, while the shipping room must of necessity be on the ground floor. The delivery service of any store is an expense, and if it can be economized it must by attention to loading, for the unloading must be by the package and to widely scattered customers.

CONGESTION AT TERMINALS.

One of the greatest causes for the loss of the time of men and vehicles is at the receiving and delivering stations of the rail and water transportation companies. Few of these stations are adequate in size, many have but a single platform for incoming or outgoing shipments, and with few exceptions hand trucks are used. There are periods when the workers are frantically busy, while without may be in waiting a large number of men and vehicles. The shippers all want to deliver at the same time, and the others awaiting deliveries are as anxious to receive them. There is no means of knowing how much time will be required to deliver a shipment, for instance, and because of expected delay the vehicles are dispatched with what may be considered ample time to get the freight into the hands of the transportation companies. This further insures loss of time, and with this certainty of waste it is obvious enough that the least expensive vehicle to operate and maintain appeals to the man who realizes that he is compelled to sacrifice time and services.

No matter what the inclination of the shippers or the facilities they have for economic haulage, there can be no improvement so long as the rail and water transportation companies do nothing to facilitate handling of freight. Apparently many of them are wholly indifferent to the cost to their customers. It might be possible for commercial bodies and organizations of shippers to bring about improvement by concerted action and co-operation with the carriers, but this appears to be the only practical solution of the problem.

LIGHTS ON ROAD VEHICLES.

There is no doubt of the need of lights on all road vehicles, no matter where used, as protection for person and property. In several states laws requiring such lighting are in effect. In other commonwealths endeavor has been made to bring about the enactment of similar law, but the bills have been defeated because whatever influence is brought to bear is usually evidenced at committee hearings, and no matter what the attitude of the committee the legislators as a whole must be considered. To secure the enactment of laws of this character it is necessary to create public opinion as to the benefits, which can only be done through constant agitation and concerted effort by all interested. Here is opportunity for the owners of motor power wagons to exercise their influence and bring about good legislation and proper administration of the statutes.

ECONOMICAL LONG DISTANCE MILK HAULAGE.

Five-Ton Alco Saves Owner Between $8 and $9 a Day, Besides Improving Efficiency of the Service---Splendid Growth of Business Results from Progressive Methods.

FEW cities in the country appear to be better able to appreciate the value of the mechanical transport than Springfield, Mass. The visitor who stands on Court square cannot help but be impressed with the varied uses to which motor business vehicles have been put. It claims to be the first city in the country to utilize gasoline driven fire apparatus. The United States mail is collected by a uniformed rider on a motorcycle with van attachment. It almost seems as if every line of business were represented, and nearly all users report decided success. Sometimes this result surprises the investigator, for in other sections certain lines render reports which seem to indicate the impracticability of utilizing motor vehicles because of the conditions surrounding the installation.

The entire plant is as sanitary as it can be made. The stables for the horses are concrete floored with patent gutters, traps and drains for carrying off the refuse, and are separated by a concrete wall from the remainder of the plant. The wagon shed also is concrete floored, sloping in places to drains so that the water used in washing can run off readily. In the rear are the rooms used for separating and bottling the milk and cream, the washing of the cans and the storage of cans and bottles. Adjoining the bottling room is the room where the cream separator is installed, while in the extreme rear are the furnace rooms and garage. Everything that would tend to the elimination of waste movement and surplus energy is utilized, the effect being the maximum of service with

Alco Five-Ton Truck Utilized in Long Distance Milk Haulage, in Front of Charles A. Nash's Bottling and Distributing Plant on Oakland Street, Springfield, Mass.

the minimum of effort. In the near future it is proposed to add machinery for pasteurizing, clarifying, refrigerating and bottling, and a greatly improved separator.

Perhaps Springfield has better means of solving the difficulties presented, or it may be that the more general application of the mechanical transport carries with it features which render the problems less acute.

Many Springfield men are free to attribute their business success to the use of motor vehicles. This is in a large measure true of Charles A. Nash, a milk dealer located on Oakland street. Five years ago his business of supplying families with bottled milk was handled by three one-horse teams. Today, seven such wagons distribute 3300 quarts of milk and 125 quarts of cream daily. The business employs 17 people, including drivers, barn men, bottling men, helpers and office clerks.

It must not be presumed that this splendid increase in business and the facilities with which it is handled are entirely due to the use of a motor truck, but Mr. Nash is using a five-ton Alco, made by the American Locomotive Company, New York City, and purchased through the Morse-Readio Company, the Springfield agent, with the result that he is saving between $8 and $9 a day in the handling of the milk. Moreover, he has been able to increase the supply of milk received each day through his ability to handle the

product more directly and in much less time.

Springfield has a population of 88,926, according to the census of 1910. The cities of Holyoke, with 57,730, and Chicopee, with 25,441, virtually are a part of what might be termed the "metropolitan district" of Springfield, and to these figures must be added 9224 for the town of West Springfield. Statistics are not available for the towns of Longmeadow and Ludlow, which add perhaps as many more. Westfield on the west, with 16,044, and Palmer on the east, with 8610, also must be supplied with milk from the agricultural district immediately surrounding Springfield. This presents a total of between 200,000 and 225,000 people who make up the market for milk producers in that section, and explains the necessity for bringing the milk a long distance.

Practically all of Mr. Nash's supply comes from the farms in Gilbertville and Old Furnace, in Worcester county, the former being approximately 33 miles from his plant on Oakland street. Before he purchased the Alco truck he was dependent upon the railroad for haulage, and two receiving stations were established, one in Gilbertville and the other in Old Furnace. The farmers delivered their milk at these stations early in the morning, whence it was picked up by the train men and brought to the freight house in Springfield. It then became necessary to cart the milk from the freight house to Oakland street. At first this was done by teams, but later it was found more advantageous to arrange for this work by contract.

None of the milk is delivered to the customers until the morning following its arrival in Springfield, but the necessity of bottling, etc., make it extremely desirable that it should be at the plant as early as possible after its arrival in Springfield. Since the railroad handled all manner of freight, the arrival of the milk was dependent more or less upon the amount of business picked up by that train on its way from Athol. In the effort to expedite matters an express man was employed who utilized a motor truck, and it was while engaged in studying the work done by this vehicle that Mr. Nash became interested in the possibilities of motor truck delivery direct from the receiving stations in the country.

After investigating the various makes available, he decided upon the Alco, to which he fitted a specially designed body, capable of carrying the cans in two tiers. As will be noted by the accompanying illustration, the entire load is protected from dust and dirt, and in a measure from the heat of the sun, by a canvas covering. The milk is loaded ice cold, and the run from Gilbertville to Springfield is made in from four to 4.5 hours, so that the temperature has risen but little upon its arrival. The truck is fitted with dual block tires in the rear and solid rubber tires in front.

The Seven Single-Horse Teams Which Comprise the House-to-House Delivery System Employed by Charles A. Nash.

One man leaves the Oakland street plant with a truck load of empty cans at 4:30 every morning, Sunday included, driving directly to Gilbertville, 33 miles. Here he finds the farmers awaiting his arrival, and they assist him in loading the milk, so that the wait at Gilbertville averages about 20 minutes. The larger portion of the load is picked up at this station, after which there is a drive of 4.5 miles to Old Furnace. The road over this portion of the journey is not especially good, although it averages well with the old country ways of the district. Other farmers are waiting at Old Furnace and the stop there does not exceed 15 minutes. Then begins the journey of 28.5 miles to Springfield, most of the way being over state macadam, except for three or four miles beyond Ware, which is in much the same condition as the 4.5 miles previously mentioned. The truck arrives at Oakland street between 1 and 1:30 in the afternoon.

The full cans are immediately unloaded and taken into the large, concrete floored bottling room, where

the racks of bottles, which previously have been washed and sterilized, are already in place on wheeled hand trucks. As fast as the bottles have been filled they are immediately taken to the ice chests, so that the temperature is not permitted to change more than is absolutely necessary. That portion of the load which is destined for the separator, in order to produce the daily allowance of 125 quarts of cream, also is handled as expeditiously as possible. Everything is in readiness for the drivers long before they start out on the delivery trips the next morning. The main object of the plan is to handle the milk quickly, particularly in warm weather, so that it shall be cooled properly at all times, and in this respect the use of the motor truck is of decided advantage over the older method of handling by railroad train men.

Mr. Nash has kept careful account of the expense, it being recognized by him that each department of the business must be managed as economically as possible, consistent with protecting his customers. The truck uses an average of 19 gallons of gasoline and three quarts of oil a day. The tires are purchased on a guarantee basis, the rear members being guaranteed for 8000 miles and the front for 10,000. Actual experience has indicated that in this work, over the roads traversed, which are by no means ideal in places, as has been explained, the block tires will average 3500 miles and the solid members on the front a little better than 4000, before being regarded as unsuitable. While Mr. Nash does not care to go into details concerning all of the items in the truck's expense account, he states that it totals between $12 and $13 a day. This includes an allowance for depreciation and interest, and the driver's salary of $21 a week, but no provision for garaging or repairs. The machine is garaged on the premises at the Oakland street plant, and thus far there has been no expense for repairs or replacements.

Under the old system Mr. Nash paid a freight charge of five cents a can each way, besides employing the contractor to haul the milk from the freight house to the Oakland street plant. The total expense averaged about $21 a day. This was for cartage alone. The necessary delay in receiving the milk and the impossibility of arranging to care for it at a stated time were responsible for some overtime work, the expense of which should be added to this figure. And, of course, the inefficiency of the system cannot well be reduced to dollars and cents.

Although Mr. Nash has found this truck a decidedly successful investment, he does not believe that motor vehicles ever will entirely displace horses in the milk business. He does not see how any car, operating either with gasoline or electricity, can compete with a horse and wagon in house-to-house delivery, for the reason that horses in this work soon learn to cover the route, so that the driver is able to take, say half a dozen bottles of milk and visit as many houses to come out of the last one and find the team waiting for him. With the automobile he would be compelled to return to the starting point each time.

TRUCK DIVES INTO MILL POND.

KisselKar Brewery Machine Plunges from Stone Wall and Is Little Damaged.

When a two-ton KisselKar wagon in the service of the Joseph Schwartz Brewing Company, Hartford, Wis., plunged from a 10-foot stone wall into the bed of a mill pond in that city it demonstrated the construction of the machine in a manner that was as surprising as it was convincing. The "header" was a drop into shallow water and the machine brought up with the front wheels resting on the bottom and the rear wheel on the edge of the wall, the jackshaft being partly on the stone.

Two-Ton Kissel Truck After It Had Battered Down a Stone Wall and Plunged Into a Mill Pond, with a Flattened Muffler and Bent Running Board as the Only Damage.

The truck was seen by hundreds and there was general belief that it was hardly worth a tenth part of the purchase price, but a derrick was obtained and after a couple of hours' work the supposed wreck was hoisted on to the road. When examined there was much astonishment in the fact that aside from a badly bent mudguard and a crushed muffler the machine was not damaged.

This opinion was, moreover, established when the afternoon of the same day it was sent to the brewery and went out on an 18-mile trip. In further service there developed no weaknesses which were considered as due to this accident.

LONDON MOTOR OMNIBUS SERVICE.

THE omnibus service in London is the largest in the world. The city has a very large part of its streets well paved and the service given is unequalled in any other city. The following review of the service and of the vehicles used was given by President T. B. Browne, of the Institution of Automobile Engineers of England, in an address made by him at the recent midsummer meeting of the Society of Automobile Engineers:

The motor omnibus seems to have made comparatively little headway as yet in this country and I have therefore thought that some details of the large and efficient motor omnibus service of London may prove of interest to you. According to the figures furnished to me by the courtesy of the commissioner of police, the number of motor omnibuses licensed during 1912 for use in London was 2908, so that with the subsequent additions there are now more than 3000 of these vehicles in use in the metropolitan area, as compared with about 1000 in Paris. It may be of interest to state here in passing that there are over 8000 motor cabs licensed in London alone.

The whole of the petrol propelled motor omnibuses running in London are now either owned or controlled by the London General Omnibus Company, and its subsidiary companies, including the Stevens-Tilling petrol-electric vehicles which I shall describe later. The only independent company is the National Steam Omnibus Company, who construct and run the highly successful vehicles designed by one of our members, Mr. Thomas Clarkson, who is giving a paper devoted to them before this meeting.

The first requisite for the successful use of motor omnibuses in competition with street tramcars is, of course, good roads, and in this qualification London and its environs are now second to no other town and it is largely owing to this that the motor omnibuses have been able to compete so favorably with the electric trams or trolley cars as you call them here.

Two main factors have principally conduced to the present efficiency of the petrol omnibuses as now running on the London streets and these are firstly, the insistence of the police authorities that the vehicles should comply with a high standard of noiselessness and reliability combined with a low maximum weight limit, and secondly, the determination of the constructors to produce vehicles capable of passing these tests. As an example of the difficulty of passing the police inspection of these vehicles it may be mentioned that cases have been known where vehicles have failed to obtain a license to run solely on account of the hissing noise caused by the passage of the air through the carburetor inlet, great trouble being caused by this defect alone until a suitable carburetor was discovered.

The police regulations as to weight, which are strictly adhered to, include the following maxima:

Complete omnibus, unladen	7,840 pounds
Back axle weight, laden	8,960 pounds
Front axle weight, laden	4,480 pounds
Total weight, laden	13,440 pounds

The last three figures include an allowance for 16 inside passengers and 18 outside, as well as the driver and conductor, of 140 pounds each. As regards dimensions, the total length must not exceed 23 feet and the breadth seven feet two inches at any part, the maximum wheelbase being 14 feet six inches and the wheel track or gauge not less than five feet six inches. There are also many other arduous but necessary regulations as regards brakes, steering gear, the prevention of smoky or otherwise offensive exhaust and leakage of oil from engine and transmission cases. Supporting bars have also to be fitted to minimize risk of danger from broken or falling parts such as cardan shafts and there are many strict rules as regards dimensions and other details of the body, also in reference to lighting, prevention of rattling, etc., etc.

It may be well to point out that at the present time there are still a certain number of the most successful of the older types of motor omnibus running in London which do not in every way comply with the latest regulations as regards the present weight limits which they slightly exceed, but it has been the policy of the police not to deal harshly with the owners who have already received licenses for these vehicles under earlier regulations. The vehicles still running under this category belonging to the London General Omnibus Company, include 118 De Dions, having spur and bevel transmission and cardan shaft drives to the rear wheels, also 60 Straker Squires with chain driven, change speed gears, the power being transmitted to the road through worm gear and final chain drive. Besides these there are some Leylands with spur change speed gear and final live axle worm drive.

The chassis which has been specially designed by the London General Omnibus Company and has stood the test of the strenuous regulations mentioned above is known as the B type. Of these some 2200 have now been constructed and put on the road and their reliability is shown by the charts giving the percentage of involuntary stops and those ordered by the police. The total distance covered by the London motor omnibuses a month is now averaging over 8,000,000 miles, the total miles lost from all causes by the B type vehicles for March last being 0.136 per cent. of the total possible mileage. The involuntary stops from all causes a 100 miles was 0.012, or say 12 stops for every 100,000 miles. In 1912 the total number of omnibus passengers carried in London was 492,858,934. Before starting to build its own chassis some 32 different kinds of motor omnibuses had been tried and used by the London General Omnibus Company, including petrol-electric, steam and petrol. Undoubtedly, one of the principal factors which have led to the successful results achieved has been the undertaking of the construction of the vehicles by the actual users, as in this way there is no clashing of interests between maker and user in tracing and removing defects and the experience gained in running and maintenance has been most valuable in arriving at the most suitable methods of design, construction and also in the choice of material.

A close alliance of this nature exists in every case where success has been attained, namely with the London General Omnibus Company, the National Steam Omnibus Company and the Tilling-Stevens system.

In the case of the London General Omnibus Company, nearly 400 motor omnibuses have been supplied by the Daimler Motor Company, but these vehicles are a development of the B type mentioned above and the most important differences between these two chassis are mentioned later. The London General Omnibus factory at Walthamstow, which is capable of an average output of 30 vehicles a week, as well as supplying renewal parts for 2500 motor omnibuses, is one of the best organized in the British Isles, and has been laid out especially for the production of the one type of chassis with the consequent economy in the cost of production. The Daimler company have also organized a special department of their factory for turning out 30 omnibus chassis a week.

I have not time here to deal with the wonderfully efficient organization for the running and maintenance of the motor omnibuses and it must suffice to say that there are 35 garages with fully equipped repair departments attached, situated in convenient parts of London, controlled by the London General Omnibus Company alone.

It will now be interesting to see in what way the various defects in the earlier vehicles have been overcome in order to comply with the stringent police regulations already mentioned.

Owing to the courtesy of Mr. W. J. Iden, chief engineer of the London General Omnibus Company, I am enabled to publish for the first time drawings showing details of the B type chassis as constructed by that company. It will not be necessary to describe the various parts in detail, so that I propose only to touch on the points which are of particular interest as illustrating the special requirements for an omnibus chassis as distinct from a lorry chassis designed for the same load.

One is at once struck by the comparative slenderness of the main members of the frame, the longitudinal members of which consist of 1.75-inch thick ash on either side of which are riveted .1875-inch nickel steel plates. These side members are of uniform depth for about half their length from the rear, the depth of the forward half being increased as shown. Although the average life of most of the parts of the B type vehicle is now known to its constructors, that of the frame has not yet been ascertained as none has yet had to be scrapped.

To account for this it must be remembered that the body which consists of an extremely rigid box-like structure is bolted to the frame and therefore acts very much as a stiffener to it. This combined wood and steel frame is said to be much superior to a pressed steel frame in reducing the noise from the transmission as heard inside the omnibus.

Another notable feature of the frame is its height from the ground, namely, two feet 10 inches at the upper surface and well above the average height for motor vehicles. The main reason for this is to obtain a straight through horizontal drive from the crankshaft to the worm driven live axle and at the same time to provide the ample clearance under the vehicle as insisted upon by the police. The diameter of the driving wheels is also a factor here.

One of the special features of the engine is the system of lubrication employed for the connecting rod big ends. This consists of troughs into which small scoops attached to the connecting rods dip when at their lowest point and so pick up the correct amount of oil. Since this system has been adopted, all trouble from smoky exhaust has disappeared. One of the main differences between the London General Omnibus and the Daimler engine is that poppet valves are used for the former while the latter uses a Knight sliding sleeve valve motor. With this engine it has been found advisable to arrange for the troughs to be slightly raised or lowered with the throttle so as to vary the amount of oil supplied with the M. E. P. All engine bearings are of white metal and the main bearings are lubricated under pressure by means of a rotary pump.

The dimensions of the London General Omnibus engine are 115 mm bore by 140 mm stroke, the Daimler engine being 110 mm bore by 150 mm stroke. Both engines have their valves actuated by saw-tooth chain drive from the crankshaft and are not fitted with governors, the throttle being controlled by a pedal. The various pipes on the engines are made up from steel stampings in two halves which are welded together and have the flanges attached by the acetylene process, and are then lead coated inside and out, which makes a very quick, clean and economical job.

The poppet valves of the B type engine have recently been enlarged from 36 mm to 42 mm. These valves are now made from mild steel and are case hardened and ground all over.

Formerly they were made from 10 per cent. soft nickel steel and only hardened at the tappet end so that the stem wore and caused leakage of air between them and the inlet valve guides, which upset the carburetion and created a spitting noise by the escape of the exhaust in the same way. The London General Omnibus Company relies on thermo-syphon for water circulation, but the Daimler company prefers to use a rotary pump. Both now use the same pattern radiator, which consists of vertical copper tubes, the ends of which are expanded and soldered into the top and base tanks of the radiator. Bosch high-tension magnetos are used on all engines. The magneto is enclosed in an aluminum case which the driver is not allowed to touch.

The carburetor is of the two-jet type, the main jet being fitted in the centre of the choke tube in the ordinary way, and the auxiliary jet in the centre of the float chamber. The throttle valve is hollow and the centre chamber thereof is connected by a small passage to the auxiliary jet, so that when the valve is almost closed for slow running the main jet is cut off and gas passes through the centre of the valve from the auxiliary jet, the air passing through a ball valve. Cold air comes in to the main jet from the bottom of the carburetor and hot air through the pipe shown on the left. With this carburetor the petrol consumption varies from seven to 10 miles a gallon according to the nature of the route on which the vehicle is run. The clutch is of the ordinary leather cone type.

The universal joints connecting the engine with the gearbox and the gearbox with the worm drive live axle are of special design and are fitted with ball bearings to save wear on the moving parts which, if plain bearing surfaces are used, are liable to rattle badly as soon as slight wear occurs. The Daimler company has been experimenting with a type of universal joint in which leather discs are employed to take the drive, the variations in the relative position of the two shafts being compensated for by the flexibility of the leather. This type of joint is, of course, not new as applied to fixed plant, but is novel as regards its application to automobiles. I understand that its behavior has been such that it is likely to be adopted as standard practise for this type of vehicle by the Daimler company. It is certainly cheap and simple to manufacture.

The greatest difficulty in connection with the reduction of noise has been experienced with the change speed gear. Extensive experiments have been carried out in the endeavor to minimize the sounds emitted by the indirect drives of the gears. The solution has been found by entirely replacing the spur wheels except in the case of the reverse, by silent sawtooth chain drives. These have proved to be quite satisfactory in every way in spite of the fact that the chain makers themselves were very pessimistic as to their use. The salvation of the whole arrangement is the shortness of the chains, so that with the few links employed the total stretch of the chain with wear is very slight.

For some time great trouble was caused by the leakage of oil onto the roads from the crankcase, gearbox and worm gear case. It became necessary, in order to comply with the police regulations, to cast troughs below the joints to catch the oil which escaped from them. The joints were made as tight as possible by the use of brown paper, but the mechanics when overhauling the chassis often displaced the paper, so that leaky joints were rather the rule than the exception. This objection has now been entirely overcome by having the joints carefully scraped up by hand and then fitted together without the intervention of any joining material.

The B type has a worm driven live axle. Until recently it was generally considered that worm gearing could not be made to run at anything like the efficiency of bevel gearing and so it was used by only a few firms on account of its silent running, but recent experiments at the British National Physical Laboratory and also by Brown & Sharpe, have shown that by combining careful design with accurate workmanship and ball threads of ample size an efficiency as high as 95 per cent. can be obtained in actual practise; and so we find that all the motor omnibuses of recent design now running in London, including petrol, petrol-electric and steam, are fitted with worm driven live axles. Only the survival of the fittest can decide whether the Lanchester hollow worm or that of the straight pattern is superior. At present the former is only used on the Daimler 'buses of which there are now nearly 300 running in London under the control of the London General Omnibus Company. With the straight worm the double thrust can be fitted at one end to allow for expansion and contraction caused by temperature variations, but with the hollow worm they must be fitted at opposite ends to keep the worm in its correct relative position to the worm wheel. The axles of the two types are very much alike, the sleeves being bored from the solid. The Daimlers have hollow worms, giving a reduction of 7.25:1 and splined keys are used wherever possible instead of single loose keys. The B type axle has straight pattern worm gear with a reduction of 7.33:1, the worm having three starts and the worm wheel 22 teeth. In both types the complete worm gear is held in bearings fixed to the upper part of the axle casing, which can be entirely removed with the worm gear by taking off a few bolts, the shafts from the differential to the wheels being inserted from the outer ends of the sleeves. The live axle is designed so as to be easily removed from the chassis and an axle has been changed on the road in 45 minutes. The Daimler company uses roller bearings on both axles, the London General Omnibus practise being to use plain floating bushes of phosphor bronze.

The road wheels are made from special steel castings with hollow spokes; the weight of the rear wheels without tires is under 200 pounds each, that of the front wheels being under 100 pounds, including hubs and bushes. Various kinds of solid tires are used and are supplied by the tire makers, who guarantee the mileage, which averages about 20,000 a set of tires, the cost being about one penny a mile. Twin tires are used on the rear wheels and single tires on the front wheels, the standard dimensions being as follows: Rear wheels, twin tires, 100 mm by 1000 mm; front wheels, single tires, 120 mm by 900 mm. These dimensions are practically limited by the maximum weight allowance as fixed by the police and it is probable that greater economy in wear of the tires would result if larger tires could be used to relieve the transmission of all braking stresses. Both foot and hand brakes are situated on the rear axle and are actuated by expanding shoes inside drums bolted on the rear wheels.

A point of interest about the springs is the auxiliary volute spring fitted to the rear axle, so that it only comes into action after the leaf springs have taken about 70 per cent. of full load in the usual way. The addition of this volute spring has added very greatly to the comfort of passengers, as it has overcome the difficulty of providing correct suspension for both a full and empty omnibus.

Throughout the chassis it has been necessary to use extremely high grade materials to keep within the weight limit and comparatively few iron and steel castings are used, the complete list of these being the cylinders, road wheels, brake drums, steering box (two pieces), back axle casing, worm casing, two spring carriers and the exhaust branch from the engine, which cannot be made from a steel stamping owing to warping due to high temperature. The steel stampings used comprise the flywheel, all frame brackets, including change speed and spring brackets; also the halves of engine pipes mentioned above.

As mentioned above there are about 120 petrol-electric motor omnibuses running in London constructed on the Stevens-Tilling principle, in which the transmission from engine to the worm driven live axle is by an electrical set, consisting of a compound wound dynamo, direct coupled to the engine, and a series wound motor coupled through a cardan shaft to the worm.

The engine has four cylinders, 105 mm bore by 125 mm stroke, cast in pairs, high-tension Bosch ignition, a Solex carburetor and the trough system of lubrication being used. The dynamo is connected direct to the engine by means of a flat leaf spring coupling, no friction clutch being used. No electric circuits are made or broken when driving, as the dynamo is designed to cease to excite when its speed falls below 300 revolutions a minute, so that by nearly closing the throttle, which is effected by releasing the throttle pedal, the torque of the motor is reduced to zero.

The dynamo is capable of maximum output of 20 kilowatts at a speed of 1400 rpm, with a maximum e.m.f. of 300. The control is effected entirely by the gas throttle pedal, except when ascending very steep hills, in which case a shunt resistance contained in the controller box is employed to allow of increased engine speed. The dynamo and motor are of the semi-enclosed type and are ventilated by a disc fan carried on the rear end of the dynamo shaft, which as well as the motor shaft is carried on ball bearings. The efficiency of the dynamo is given by the makers as 90 per cent. and that of the motor as 88 per cent., making a total of 79.2 per cent. efficiency of the electrical set.

The average running costs of these vehicles as supplied by the makers is given as just over 7d a mile and the author is of the opinion that this would be just about on a par with those of the London General Omnibus Company, but as the figure for running these vehicles has not been published this cannot be regarded as anything more than a guess.

The Paris omnibuses have developed on entirely different lines from those used in London and are of the single deck type, constructed to take from 30 to 35 passengers, with the driver's seat situated on top of the engine. A spur gear change speed box, having three forward speeds, is used in conjunction with a bevel gear from which the power is transmitted through cardan shafts and internal spur gears on racks to the driving wheels, as it is not practicable to obtain the reduction required in a single bevelled pair. The motor used in these vehicles has four cylinders, 125 mm bore by 140 mm stroke. The tires used are 140 mm by 900 mm single on front wheels and 160 mm by 950 mm twin on rear wheels. The weight of the chassis is 3350 kilograms; the weight of complete vehicle empty, 5100 kilograms; the weight of complete vehicle full, 7800 kilograms.

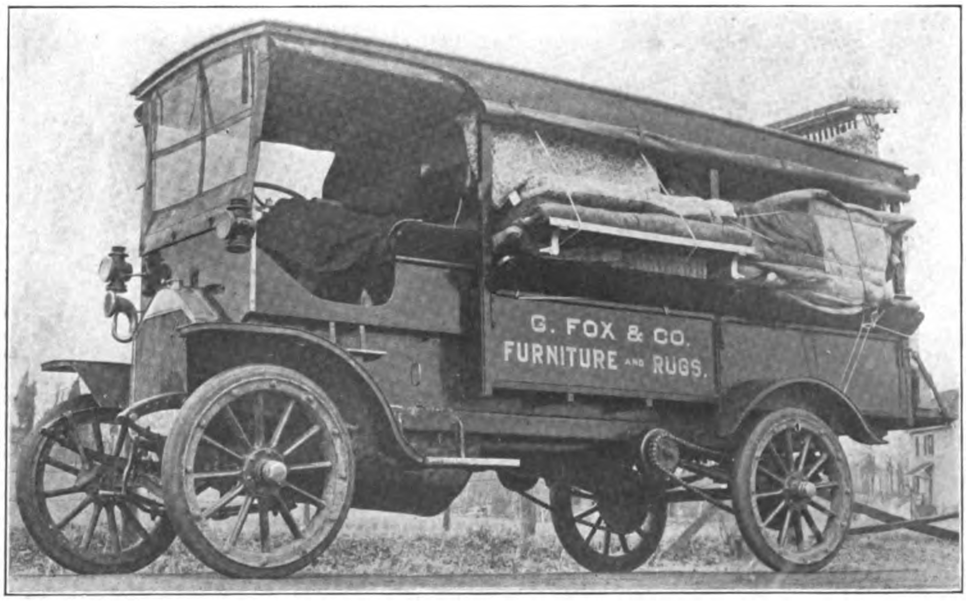
A field day will be enjoyed by the members of the Motor Truck Club of New York, Aug. 19, at the Marine & Field Club's grounds at Gravesend Bay, L. I., at which features will be field sports and a baseball game, and there will be a dinner, but without formalities. During the day the prizes offered in the membership contest now progressing will be awarded.

One of the features of the Labor Day observance in Milwaukee, Wis., will be the motor truck parade projected by the Milwaukee Automobile Club. A committee headed by Oscar Stegeman of the Stegeman Motor Car Company is working to make the event of large proportions.

DEPARTMENT STORE CONTRACT DELIVERY.

THE delivery by department stores is not always done with the equipment they own, and while it may be cheaper to own vehicles that can be constantly utilized, it is also a fact that the demands are so varying that great elasticity is necessary to meet them at all times. Most department stores endeavor to promote business when normally there would be a diminished volume, and as these sales attract purchasers from considerable distances, and sales are often of material proportions, delivery must be made. Under such circumstances recourse is generally made to those who make a specialty of haulage, and the prices are generally made on the basis of the work.

A Hartford, Conn., concern, G. Fox & Co., that has a department store of goodly size, does not own wagons or vehicles of any kind, but makes contract with different concerns to make its deliveries, these contracts providing for the regular and special work on the basis of a stated price for a day for a vehicle of a given size. In some instances owners of motor wagons contract to give precedence to the store's delivery, but are at liberty to undertake whatever work is practical and keep the contract.



The One-Ton Modern Wagon Making Contract Delivery for the G. Fox & Co.'s Department Store, Hartford, Conn.

Each owner of a vehicle having contract with the store is notified when he is wanted and arrangements are made so that he can be reached at different times during the day. An example of this service is found in a one-ton Modern wagon that is equipped with a body adapted for carrying furniture, and has a high top with side curtains. On the body is painted the name of the firm. This machine has been in use about eight months.

The wagon is used principally for furniture, rugs, carpets, etc., and it is utilized entirely for suburban delivery. The accompanying illustration was made while the machine was en route for New Britain, 11 miles distant from Hartford, and it carried the $200 load to its destination in 55 minutes. This load consisted of the full furnishings for a dining room, tables, buffet, chairs; the full furnishings for a bedroom, including a bedstead, spring mattress, mattress, chiffonier, folding couch, an extra table and a music cabinet. The following day the machine was sent out to Granby and climbed Talcott mountain with a heavy load. All of the towns in the vicinity of Hartford are covered, at least within a radius of 30 miles.

The owner of the truck says that the operating cost is about $7 a day, and that this will include all charges and with a good allowance for depreciation, maintenance and repairs. The driver has had a good deal of experience with other machines, and he is methodical in his driving and his care of the wagon. He insists that the body be clean and bright, and he is uneasy if the engine is not free from oil and dirt. Each morning he washes the chains with gasoline and greases them. He never races the engine and he is careful in engaging the clutch. He takes full care of the machine, making the adjustments minor repairs. He says that his work each day keeps the wagon in good running condition and saves no end of work at the end of each week. His care gives the owner a profitable investment and the department store has always at its service a thoroughly creditable vehicle.

From the viewpoint of the department store the contract method insures service that is practical and dependable and it has a sufficient elasticity to provide for any exigency that may arise, while there is elimination of the supervision and maintenance of equipment. G. Fox & Co. has given the contract service a consistent trial and has found that it is satisfactory. It is maintained that when a man drives and cares for his own machine he will take good care of it and will neither neglect nor abuse it, and that the responsibility that is lacking with the average hired driver is always established with the man who owns his vehicle.

The International Oil Industries Exhibition has been organized at London, Eng., for the purpose of holding an exposition of oils, greases and lubricants of all kinds at Earl's Court, London, March 24-April 4, 1914. In addition there will be a display of all kinds of lubricating devices, refining equipment, transportation facilities, fuel systems, motors, lighting and heating apparatus, and accessories. The show has been well promoted and it has the co-operation of different nations in which there are actively productive oil wells and refineries.

Municipal Service Equipment

DISCUSSES OPERATING EXPENSES.

Chief Engineer of National Board of Fire Underwriters Presents Interesting Comparative Figures.

Although he disclaims any attempt at a detailed consideration of motor fire apparatus in his report, nevertheless, George W. Booth, chief engineer of the committee of fire prevention of the National Board of Fire Underwriters, in his paper read at the recent annual convention of the National Fire Prevention Association, gave a more thorough, informing and authoritative resume of the entire subject than has hitherto been set forth in short space. He described at some length the types, uses and advantages of the various kinds of apparatus. He divided his subject into three classes, pumping engines, hose wagons and ladder trucks, also explaining numerous sub-divisions. Coming to the subject of service, he said:

The question of reliability under varying conditions has been much discussed by fire department officials. It is the general opinion that automobile apparatus, if properly cared for, is at least as free from break downs and delays as horse drawn. On bad roads there may be conditions of deep mud or sand or deep soft snow, where horses will struggle through and the automobile will fail because the wheels are not able to secure traction; but on the other hand, if there is any firm bottom which the driving wheels and chains can grip, the automobile will plough through stretches of bad going where horses would certainly become stalled.

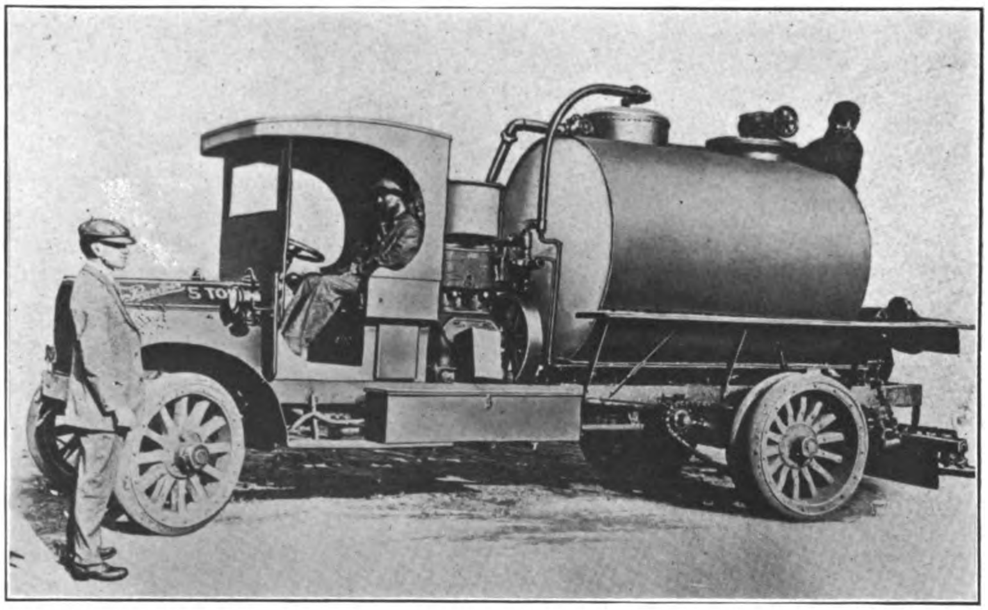
The reliability of the gasoline engine for driving pumps, as compared with the steam fire engine, has been questioned, although many chiefs who have used automobile pumping engines under trying conditions are ready to testify as to the effective results. As in any similar case where new problems are presented, considerable time and experimenting are required to develop a satisfactory machine; much progress has been made in the past year or two, although there is, of course, room for further improvement. The tests of pumping engines to be conducted at the convention of the International Association of Fire Engineers, in New York, in September next, which are to continue for a period of 12 hours, should go far towards establishing a fair comparison of performances.

The question of the relative economy of automobile and horse drawn apparatus is complicated by the uncertainty of such items as depreciation and repairs; automobile fire apparatus has not been in service long enough, at least in its present fairly well standardized form, to furnish reliable service records, nor are the records detailed and accurate enough in many cases to provide fair comparisons; consequently any estimates made now are subject to material revision. The following tabulations were compiled from study of records of over 20 cities, and what is considered a liberal allowance was made for the items of depreciation, repairs and operation, each one being three or four times as great per mile as the corresponding items for commercial trucks, as derived from carefully kept records for a number of years. The conditions governing the use of fire apparatus are such that the cost per mile of maintaining and operating it will be considerably greater than for commercial apparatus; the two main items of expense are for interest and depreciation, and any probable variation in the other items will not materially affect the result. As to depreciation, the commercial truck is expected to survive a mileage of 80,000 or 100,000 miles; of course, nothing like this mileage is to be expected from fire apparatus, since a yearly total of 500 miles is probably a high average, and a life of 25 years is assumed, not because the apparatus will be worn out at the end of this time, but because it is likely to be discarded for something better.

It will be noted that the yearly cost of apparatus for a horse drawn hose wagon is figured at $1800, as against $1420 for a tractor drawn steam engine and an automobile hose wagon, $1200 for an automobile pumping engine and an automobile hose wagon, and $780 for an automobile combination pumping engine and hose wagon. It is assumed that only two horses will be used on the steam engine; this is a common condition, but three horses are often used for large engines and where steep grades are encountered, and this will add about $260 to the yearly cost. It may be contended that 25 years is too long a life to expect for fire apparatus; however, the same life has been assumed for all classes of apparatus, so that the difference in cost of maintenance, whatever the life assumed, will be practically the same for all classes as noted here. The only item affected will be that of depreciation; if a life of 20 years is assumed instead of 25 years, $10 must be added to the depreciation item for each $1000 of the original cost. The cost of fuel for operating a pumping engine at a fire will be about $5 per hour for the steam engine, and $2.50 for the automobile.

For a ladder truck or water tower a tractor will show a slight saving over a two-horse hitch and about 40 per cent. saving over a three-horse hitch.

In this comparison no mention has been made of the number of men needed to operate apparatus. Although it is likely



Peerless Five-Ton Chassis Fitted with Specially Designed Tank for Transporting Heated Road Oiling Material.

that in many cases there will be no reduction in the number of men per company, the substitution of automobile apparatus for horse drawn will mean that one and often two more men will be available for active fire duty, and this is an important consideration in view of the tendency towards a weakening of the strength of companies through the granting of more time off.

COMPARATIVE FIRE APPARATUS FIGURES.

Hose Wagon—Horse Drawn.	Cost a Year
Cost, $2000.	
Interest at 4.5 per cent	$90
Depreciation, based on life of 25 years	45
Repairs and tires	30
Total	$165

Steam Fire Engines.	Cost a Year
Cost, $5500.	
Interest at 4.5 per cent	$247
Depreciation, based on life of 25 years	124
One new boiler and general overhauling costing $2000	84
Tires and repairs	70
Total yearly cost for engine	$525
Interest, depreciation and coal for heater	90
Total	$615

Two Horses.	Cost a Year
Cost, $600.	
Interest at 4.5 per cent	$27
Depreciation, based on life of 7 years	60
Shoeing	90
Veterinary	25
Harness	6
Forage	300
Total	$508

Two-Wheel Tractor.	Cost a Year
Cost, $4000.	
Interest at 4.5 per cent	$180
Depreciation, based on life of 25 years	90
Repairs, 9 cents a mile	45
Tires	40
Operation, 7 cents a mile	35
Total	$390

Automobile Hose Wagon.	Cost a Year
Cost, $5000.	
Interest at 4.5 per cent	$225
Depreciation, based on life of 25 years	112
Repairs, 9 cents a mile	45
Tires	60
Operating, 7 cents a mile	35
Total	$477

Automobile Combination Pumping Engine and Hose Wagon.	Cost a Year
Cost, $9000.	
Interest at 4.5 per cent	$405
Depreciation, based on life of 25 years	202
Tires	80
Repairs, 10 cents a mile	50
Operation, 8 cents a mile	40
Total	$777

Steam Fire Engine with Tractor.	Cost a Year
Cost, $9000.	
Interest at 4.5 per cent	$405
Depreciation, based on life of 25 years	202
New boiler, etc	84
Heater cost	90
Repairs and tires	125
Operation of tractor	35
Total	$941

Summary.	
Steam fire engine, horse drawn	$1125
Hose wagon, horse drawn	675
Total	$1800
Steam fire engine and tractor	$940
Automobile hose wagon	480
Total	$1420
Automobile combination pumping engine and hose wagon	$780
Automobile hose wagon	480
Total	$1260
Balance in favor of steam engine and tractor, over engine and horses, for year	$380
Balance in favor of combination pumping engine and hose wagon and automobile hose wagon, over horse vehicles, for year	$540

Cost of operating at fires would be as follows for a five-hour run, with two good streams:

Steam fire engine, 4 tons coal, at $5	$20
Gasoline engine, 60 gallons gasoline, at 17 cents	10

The main features of design of the various makes of apparatus have become fairly well established; there will undoubtedly come, after the period of experimentation is over, a standardization and simplification of details, which will reduce the cost of manufacture and facilitate repairs, and will be accompanied by a constantly increasing reliability.

PEERLESS IN ROAD OILING WORK.

Problem of Hauling Heated Material Long Distances Is Solved Effectually.

The problem of applying oil to the road surface at a distance of 20 miles or more from the starting point and to spread the material at a heat of 200 degrees or over, is one which has been solved effectually by the road commissioners of Los Angeles county, California, by the use of a Peerless five-ton truck, made by the Peerless Motor Car Company, Cleveland, O. As will be noted by the accompanying illustration the body has been especially designed for the purpose.

The chassis is fitted with a 1000-gallon oil tank, and the latter is covered with a coating of asbestos two inches thick. Oil is run into the tank at a temperature of 350 degrees, Fahrenheit, and thanks to the heat retaining quality of the asbestos protection and the speed at which the truck may be driven, it is possible to cover as many as 35 to 40 miles before the oil is too cold for use.

Air pressure of 60 pounds to the square inch is maintained inside the tank by an air compressor operated by the same mechanism as that used to actuate the dumping body for sand and gravel utilized with Peerless trucks. Heat from the motor exhaust is utilized to keep the oil spreader warm so that the material will not thicken and clog up at that point.

This machine covers an average of 50 miles a day, and the driver states that in 2000 miles of service only two involuntary stops were necessary on the road, both of these being caused by dirty gasoline stopping up the fuel line.

MOTOR PUMPING ENGINES.

Conditions Which Will Govern Tests During Fire Chief's Convention in New York City.

At the recent conference at New York City of the officers of the International Association of Fire Engineers, the New York sub-committee on tests and the leading manufacturers of fire appliances, the final regulations to govern the testing of apparatus were formulated. The statement of conditions governing automobile fire engines follows in part:

Exhibitors will be required to state in advance the rating they place on their pumping engines: That is, gallons discharged at 120 pounds net pressure, and at 250 pounds net pressure, or higher if the exhibitor elects; and exhibitors will be required to arrange for a preliminary test on Monday or Tuesday of convention week, or preferably during the preceding week, to verify these ratings. The preliminary test is expected to be sufficiently exhaustive to determine how much

water each engine can deliver at the various pressures before stated, but it is to be definitely understood that this delivery shall be no more than can be maintained for the full period of the final test.

An engine able to deliver, for example, 740 gallons at 120 pounds pressure, will be given a corresponding layout of hose and nozzles, unless the exhibitor desires a layout which will enable his engine to deliver its discharge at a higher net pressure. Ratings of engines will be considered as the next lower even 50 gallons than the quantity delivered at the preliminary test; for example, an engine delivering 740 gallons at 120 pounds net pressure will be rated at 700 gallons and one delivering 880 will be rated at 850 gallons.

The committee reserves the right, after the completion of the trials, to place any engine in another class than the one in which it is entered. The test will continue for a duration of 12 hours, but provision will be made for any exhibitor who so elects to continue for an additional period, delivering rated capacity at 120 pounds net pressure. The first 12-hour run will be as follows: Six hours delivering at 120 pounds net pressure the quantity determined by the preliminary test; three hours delivering at 200 pounds net pressure the quantity determined by the preliminary test; three hours delivering at 250 pounds the quantity determined by the first test. During any of the runs not more than two men at one time will be allowed to operate or care for the engine, and men may be relieved every four or six hours.

The dock on which engines will be tested is about eight feet above mean tide and the range in water level will not be more than about two feet above or below the mean. Gasoline of the same grade will be supplied for the use of all engines. Exhibitors may use any grade of lubricating oil desired. Records will be kept of the amount of each that is used.

Road tests of apparatus hauled by tractor, or for hook and ladder trucks with motors attached, will be over a one-mile course with an eight per cent. grade.

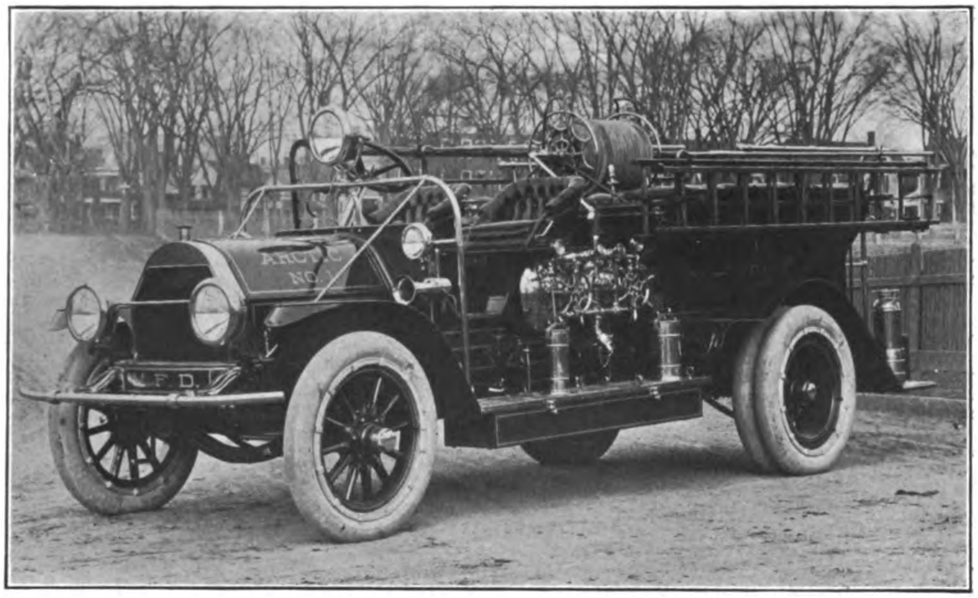
LATEST KNOX EQUIPMENT.

Double-Tank Chemical Car Now Utilizes Electric Lighting and Starting System.

An accompanying illustration shows the latest double-tank chemical wagon made by the Knox Automobile Company, Springfield, Mass., the principle feature of which is the use of electric lighting and starting, this being the first piece of fire apparatus made by this concern to be fitted in this manner. The outfit consists of the regular touring car design, made by the Esterline Company, Indianapolis, Ind. The lighting dynamo is mounted over the magneto on extension supports and is driven through silent chain. The starter has a direct drive on the flywheel through a small spur gear, and is put into operation by depressing a pedal midway of the floorboard. A storage battery of 120 ampere-hour capacity is furnished as an auxiliary.

The lighting equipment consists of Gray & Davis lamps throughout, two headlights, as well as two side and tail lamps, and a searchlight mounted on the centre of the dash. The car has a special handrail on the dash, strongly braced to enable the firemen to jump on the car while it is in motion. Another new fitting is a powerful bumper of a type similar to that which has been used with success on the Knox life saving cars in Springfield.

The Knox company also is meeting with decided



Knox Double-Tank Chemical Wagon, First Machine of This Type to Utilize Electric Lighting and Starting.

success in placing its Knox-Martin tractor with fire departments. The City of Springfield, which was the first to give this type of vehicle a trial on a water tower, has just purchased a second machine for use on a hook and ladder truck.

In the Market—Some of the cities in the market for motor apparatus are: Pendleton, Ore.; North Tarrytown, N. Y.; Milwaukee, Wis.; St. Paul, Minn.; Grand Rapids, Mich.; Concordia, Kan.; Edgewood, R. I.; Massillon, O.; Somerville, Mass.; Boston, Mass.; Lestershire, N. Y.; Brockton, Mass.; Joliet, Ill.; Rawlins, Wyo.; Pomona, Cal.; Albion, Mich.; Springfield, O.; Leavenworth, Kan.; West Springfield, Mass.; Des Moines, Ia.; Racine, Wis.; Butte, Mont.; Dallas, Tex.; Martins Ferry, O.; Jersey City, N. J.; Newark, N. J.; Middletown, O.; Northampton, Mass.; Laporte, Ind.; Fall River, Mass.; Fresno, Cal.; Lorain, O.; Tampa, Fla.; Kansas City, Mo.

New Commercial Car Accessories

Coes Screw Wrench.

The Coes screw wrench, produced by the Coes Wrench Company, Worcester, Mass., is a valuable addition to the repair shop equipment as well as to the tool box of the machine. It is constructed to withstand severe service and being all metal is not subject to broken handles, etc. The bar is of steel, fully hardened and cold swaged, while the jaw is made extra heavy, of semi-steel and hardened. The screw is steel, a one-piece construction, not a screw plus a moving dowel and a hidden spring, and is provided with a hardened and polished ball race. The handle is a semi-steel casting, internally supported and retained by cross riveting, and the extension of the bar through the handle is also riveted. The same grade of material and workmanship that has established this firm is notable in this product.

Pickup Pliers.

The Bremer-Wilson Manufacturing Company, 1421 Michigan avenue, Chicago, is marketing the Pickup pliers, which is an inexpensive tool as well as a handy instrument. It is an extension member, seven inches long when folded, but measuring 21 when extended. It is provided with a pair of jaws having milled teeth, enabling them to grip pieces of metal, such as nuts, bolts, etc., which may drop into the pan, transmission, crankcase or other place not easily accessible with the fingers. The tool may also be utilized for cleaning purposes by placing a piece of waste in the jaws and dipping it into gasoline. The pliers are constructed of high grade material, nickel plated and should prove decidedly practical.

Campbell Tell Tale.

The law requires that the tail light shall be lighted during certain periods and when the car is being operated as well as standing still. In some cities the ordinances are strictly enforced and no excuse is accepted if the driver is caught with the rear lamp unilluminated. The Campbell Manufacturing Company, 3715 Wentworth avenue, Chicago, has brought out a practical device for notifying the driver when the tail light is extinguished, and the device is made in three styles, namely: For kerosene or gas lamps, electric and combination. When utilized with kerosene or gas lamps the tell tale, as it is called, is inserted in the lamp is such manner that it is in proximity to the flame. The heat of the blaze expands the metal, thereby breaking contact between two points. If the light goes out, the metal becomes cold and contracts, contact being made between the two points mentioned, and an electrical circuit is made. Current is supplied by a single dry cell and when the connection is made by the points referred to, a buzzer is sounded, calling the attention of the driver to the lamp. The metal of the tell tale is very susceptible to heat or cold, insuring a warning in a few seconds if the flame of the lamp is extinguished. The wiring plan of the electrical unit is also illustrated and its simplicity is apparent. With either design the electric horn may be utilized in place of the buzzer if desired. The Campbell tell tale is moderately priced.

Durno Motor Starter.

The Durno Manufacturing Company, Rochester, N. Y., is marketing the Durno motor starter of the compressed air type. It differs from conventional design in that the pressure is utilized to actuate a mechanical device instead of being led to the cylinder of the motor. The mechanical member comprises a drum fitted to the front of the machine and carrying an auxiliary shaft engaging with that of the engine. The drum carries a chain attached to a rod and connected to a piston rod of a cylinder having a four-inch bore and 12.5-inch stroke. Air is admitted to the cylinder from a pressure tank which is supplied by a four-cylinder air pump operated by the motor. Pressing a lever on the footboard of the car allows air to flow to the cylinder member, forcing the piston backward and unwinding the chain on the drum. At the same time the auxiliary shaft is thrown into engagement with the motor shaft, spinning the latter, and it is held that energy is imparted slowly at first. The system is provided with a night valve for the purpose of preventing escape of air when the car is not in service. A tire inflator is part of the equipment, and includes suitable length of tubing and a gauge.

Agner Simplex Socket Wrench.

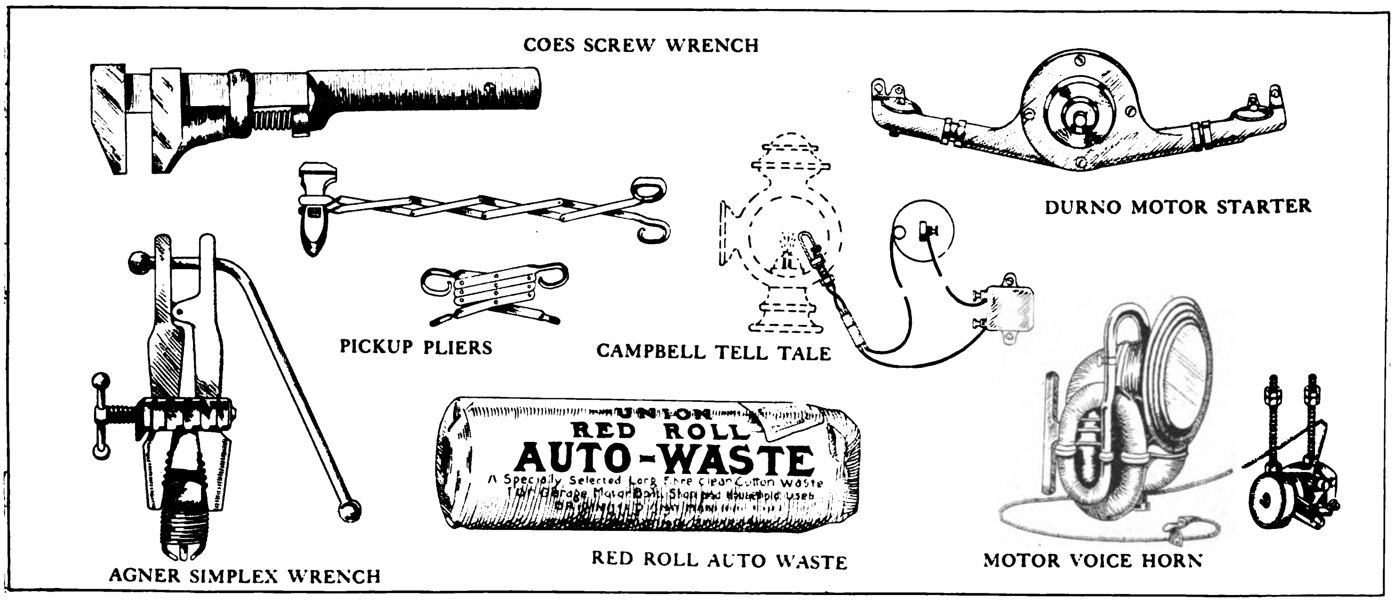
The Agner Simplex adjustable socket wrench, manufactured by the R. C. Agner Company, Burlington, Wis., presents interesting features in that it may be employed for a number of useful purposes. It is especially adapted for removing and replacing spark plugs from valve caps not easily accessible with ordinary tools, having as it does a pair of movable jaws which are locked by a small clamp. It may also be utilized on square or hexagonal nuts or bolts, or as a tap wrench. Another feature of the device is that it may be employed as a tap wrench. It is constructed of high grade material, nicely finished, and is very compact.

Motor Voice Horn.

The Motor Car Equipment Company, 55 Warren street, New York City, is marketing the Motor Voice horn, which differs from conventional signals in that energy is supplied by compressed air furnished by a small air motor. The latter is mounted on the frame of the chassis in such manner that a friction flywheel is brought into contact with the flywheel of the engine when desired. Connection between the air motor and the horn proper is by a flexible metallic tube. The air motor is actuated by a Bowden cable to which is secured a special clip mounted on the steering wheel. The horn is as easily operated as an electric and it is claimed that the tone is similar to a siren horn, as far reaching, but of a pleasing character. One of the advantages of the horn, and one that will be appreciated by the truck driver, is that it cannot be operated by the small boy when the car is standing still.

Union Red Roll Auto Waste.

The Union Wadding Company, Pawtucket, R. I., has originated a novel method of compressing into a single sturdy container, 12 separate handfuls of waste, each of which may be taken from the package without disturbing the others. The material is compressed into a compact roll sufficient for all ordinary requirements. The advantage of this packing is obvious. It keeps the waste clean, prevents tangling up in the tools, etc., when carried in the tool box; can be stored in a small space and is always handy for service. The package is but 12 by three inches, and the container is of sturdy construction. The waste is a specially selected long fibre.



Illustrating Some of the Latest Accessories Adaptable to the Commercial Vehicle, Garage and Repair Shop.

FOREIGN TRUCK NOTES OF INTEREST

LONDON MOTOR 'BUS SERVICE.

Some Factors in Their Operation Which Will Prove of Interest to American Cities.

The experience of London, England, the largest city in the world, with motor driven vehicles in public service, is of decided interest to people living in the large cities of the United States, where the traffic conditions are such that there is a constant problem of congestion. Self-propelled public service 'buses have not been adopted in America except on a small scale in isolated instances, but the matter is now attracting much attention in such cities as New York, Chicago, Philadelphia, Detroit, etc.

Since 1909 it has been amply demonstrated in London that the lower running cost a mile of the motor vehicle, its superior mobility and the greater frequency of service which is possible with the larger number of smaller units, are factors which have enabled the 34-seated motor 'bus seriously to compete with the 78-seated electric street car. The extent to which motor 'buses have developed in London may best be appreciated by the following table:

	Street Miles	No. Motor 'Buses
Dec. 31, 1909	114.8	1049
Dec. 31, 1910	121.4	1097
Dec. 31, 1911	174.1	1634
Nov. 30, 1912	336.6	2527

The fact that the noted increases in totals of motor 'buses have not led to undue congestion in London calls for special comment. The figures disclose an approximate average of 10 vehicles in service a mile of route worked, with a downward tendency in 1912, the average at the end of that year being barely eight a mile, indicating better and more careful distribution. Comparable data for the London County Council electric street cars show an average of 11.5 of the bigger vehicles a street-mile served.

The average speed of an electric car is at least two miles an hour less than that of a motor 'bus, which is able to travel an average of at least 20 miles more than street cars in a working day. Therefore, taking the smaller average number of motor 'buses a mile of street served, travelling at higher average speeds than the street cars, it is obvious that the congestion due to latter is greater. The ability of the independent vehicles to draw around obstacles, or to deviate temporarily from a disturbed route, and the absence of delays to the whole system when a failure of individual mechanism occurs, are contributory factors, the importance of which is becoming more and more realized by the proprietors, recognized by the police authorities and appreciated by the travelling public.

So profitable had the working of the motor 'buses become in 1912 and so serious a competitor had the road vehicles proved themselves to be with other forms of passenger conveyance, that Sir Edgar Speyer decided to acquire the property of the London General Omnibus Company, Ltd., the leading English motor 'bus concern, for the benefit of his electric railway undertakings. The $500 shares of the company, which stood at only $90 in December, 1909, had risen steadily to $2000 in June, 1912, and the residue of the minority, who opposed the sale, were, with the approval of the courts, bought out at $1375 for each $500 of stock a few months later.

AGRIMOTORS AND TRACTORS.

Some Foreign Tendencies as Revealed in Recent Exhibitions and Manoeuvres.

Details concerning the commercial vehicle display at Olympia, London, England, have not yet been received in this country, but it is anticipated that interest in the event will be considerably augmented by the very successful exhibition of motor equipment suitable for farm use at the Royal Agricultural Society's show in Bristol a few weeks earlier. A large section was devoted to what the British term agrimotors, or tractors designed to operate plows, hoes and other farming implements.

The Bristol display was much on the order of an old fashioned cattle show in this country. Cattle, horses and produce were exhibited in booths arranged for that purpose, and the motor vehicle section virtually was a part of the whole, being housed in sheds, etc., each more or less detached from the others. The plan offered opportunity for demonstrating the various products, thereby calling the fullest attention to their merits.

A particular feature of this year's display was the exhibition of a larger number of tractors and trailers for road haulage. This branch of the industry has received rather more attention abroad than in this country, as is evidenced by the part trailers have played in the annual military manoeuvres in Continental Europe. An accompanying illustration presents one of the Latil front-drive combinations in this year's French trials and indicates the importance which is attached to the matter of short turning radius.

Among the British products revealed recently is the six-ton Lacre chassis fitted with a new hoisting device. The motor is a four-cylinder unit rated at 40 horsepower. Drive is taken through a leather faced cone clutch of ample size by shaft to a gearbox affording four forward speeds and reverse. The gear-

box and universal form a unit, and final drive is by side chains. Fitted on the main drive between the clutch and transmission is what is termed a spring shock absorber, the object being to permit of some little elasticity between the gears and clutch when the latter is engaged.

Driven by dogs from the tail end of the gearbox, the drum shaft, which has a diameter of three inches, is carried through to the extreme rear of the chassis and runs in bearings of ample size. At the gearbox end the fingers of the clutch are double the usual length. When it is desired to transmit the drive to the road wheels, this clutch is entirely disengaged. When in position for operating the hoist, however, the dog clutch is partially engaged. When engaged to the limit the spur pinion for the hoist drive is brought forward by the sliding of the shaft, clear of the pinion, and a second dog clutch at the extreme rear end of the hoist drive is thus brought into engagement. This drives a 4.5 by 14-inch pulley direct, and provision is made for a pulley up to three feet six inches diameter.

The third position is for belt drive to threshing engines, machine tools, dynamo, etc. The shaft to the hoisting gear is controlled by a lever located at the side of the chassis frame, and a spring adjustment is provided, which enables the gear to be worked by one man. In case the dog clutches cannot be engaged owing to the position of the main clutch, the engine can be started up, and on the turn, when the dog clutches are in a position for engagement, the spring drives the gears home.

TRUCKS ON THE RUSSIAN STEPPES.

Mining Company Orders Two Commers to Replace Camel Transport Over the Barren Sands.

A feature of the development to which the commercial vehicle industry has attained is the manner in which exceptional methods of transport are being superseded by various makes of motor trucks. It is now announced that the Spassky Copper Mine, Ltd., a Russian mining company, has ordered a two-ton and a four-ton Commer for use on the steppes in place of its camel transport for the conveyance of material and supplies from the railroad terminal at Djoosale to the mines, located 250 miles distant across the bare and uncultivated steppes.

On the machines designed for the heavy work, steel tires were fitted to the wheels. As many miles of loose, shifting sand, in addition to rivers of varying depth, have to be crossed en route, the magneto, engine, coil and all parts of the transmission are adequately protected from water and sand, both as to type and position. Two drivers go with the machine on each trip, suitably provisioned for two weeks, which is the time occupied on the journey. Various appliances are fitted to the machines to extricate them from any difficulties encountered. On the rear of the truck is a winding cable, intended for service when the machine has sunk in a river bed or shifting sand. Suitable stakes and anchoring tackle are carried and the wagon hauls itself free by its own power. Roads are non-existant in that part of the world and the journey is one of the hardest tests to which a motor vehicle can be put.

Latil Front-Drive Tractor and Trailers in Recent French Manoeuvres, Indicating Short Turning Radius Provided.

ALL HORSES DISCARDED.

British Manufacturer of Cocoa and Chocolate Depends Entirely upon Motor Equipment.

One of the first British concerns to eliminate horses entirely from its delivery service is that of Cadbury Bros., Ltd., Bournville, near Birmingham, maker of cocoa and chocolate. At present it has seven vehicles, one one-ton and five 3000-pound Thornycrofts, and one 1000-pound Ford. All are worked constantly during the winter months, but during the summer it is found possible to release each machine in turn for overhaul, painting, etc.

Some of these cars cover an average of 500 miles

a week. The small are used generally in the delivery of express orders to caterers, places of entertainment and social functions, while the large deliver more important orders to customers at a distance. While no figures have been made public relative to the economy effected, the owner is convinced that deliveries are now made more cheaply than with horses. Concerning the advantages, a member of the firm is quoted as follows:

"They certainly do exist. A decided one is the speed with which delivery can now be made. It is very pleasing to a customer situated, say, 20 miles away, to receive delivery of his goods the same day on which his order reaches the works. Promptness of this kind would be impossible but for the motors, and this feature has, we are sure, brought us extended custom among local people. When comparing motor transport with railways, goods dispatched by rail need to be packed carefully in boxes, whereas, when delivery is by motor, this is unnecessary. This method of transportation offers decided advantages in the direction of promptness, advertising effect, cleanliness and general utility."

GENERAL NOTES FROM ABROAD.

Ford Wagon in Scotland—As a result of competitive bids recently opened by the Stirling County Council, Stirling, Scotland, the local agent for Ford cars, made by the Ford Motor Company, Detroit, has closed a sale for a two-seated runabout.

Opportunities in India—Many people in India are purchasing low priced automobiles for use in place of horse drawn vehicles for business purposes. American made cars are in large demand because of their price and thoroughly dependability.

Motor Trucks in Siam—Recent reports from Siam indicate the receipt of a large number of motor trucks during the past few months. The Siamese government has installed several vehicles of this type for the use of the army, and many of the merchants in Bangkok have decided to employ motor driven delivery wagons.

Electrics in Austrian Postal Service—The Austrian postal authorities have recently placed in service 30 electric motor mail vans for use in Vienna and suburbs. The vehicles are used mainly for the transportation of mails to and from the railroad stations. A new post-office garage, capable of housing 50 electrics, has been erected in Vienna.

Americans Win in Roumania—As a result of the recent competitive tests held at Ciulnitza, Roumania, under direction of the Sindicat Agricole of the Jalomitza, a co-operative agricultural institution, gold medals were awarded to two American houses, the Emerson-Brantingham Implement Company and the Pioneer-Lascelles. Three silver medals also were given to American machines. The cup of honor was awarded to the Lanz firm of Mannheim, Germany. The names of the winning American machines were not forwarded to this country.

Bread Delivery in Victoria—The advantages of motor delivery are being demonstrated in an effective manner in Eaglehawk, Victoria, southern Australia. An enterprising baker in that city recently installed a light van, with which he has been able to extend his delivery into the surrounding districts and thus materially increase his business.

Opportunities in Buenos Aires—An engineer residing in Buenos Aires, Argentina, is authority for the statement that there is a growing market for light delivery vans in several portions of the country. Regarding heavy duty vehicles, he suggests that special attention be paid to the matter of strength in the construction of machines, and that they be shod with solid rubber or steel.

Argyll Fire Apparatus—Several of the county councils in Scotland have been installing motor fire apparatus made by Argylls, Ltd., Alexandria, and that these have been giving excellent service is borne out by the testimony of the firemaster at Dundee, who reports that recently one of these machines attached to the local brigade worked continuously at a fire for 12 hours without any difficulty.

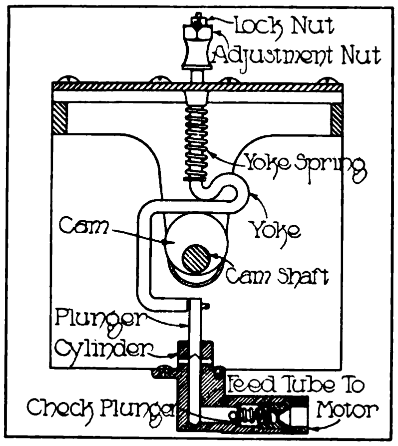
Paris Has Traffic Board—The Paris prefect of police has appointed a traffic board, which will meet on the first and third Thursdays of each month to consider all traffic problems. The president of the board will be an inspector-general of traffic, the other members being official representatives of the Cab Owners' Union, the Cab Drivers' Union, the Transport Workers' Union and the Transport Contractors' Union.

Conditions in South Africa—Recent reports from South Africa indicate that the average cost of running motor vehicles in that district is about 12 cents a mile. This is held to include use in towns and open country, although in the latter instance it is found that mere tracks exist in lieu of roads. The people are rapidly beginning to appreciate that the success of the mechanical transport depends very largely upon better highways, and a movement is under way to further good roads work in several localities.

Dennis Vehicles in Athens—The Greek government recently purchased two four-ton Dennis water tank wagons and a fire engine, made by Dennis Bros., Ltd., Guildford, England, which have been subjected to exacting tests at Castella, near Athens, under the direction of the city engineer of Athens. These are understood to be the first vehicles of these types to be used in the Greek capital, and if they prove a success, as now seems evident, it is expected that additional equipment will be purchased in the near future.

HINTS FOR PROPER MAINTENANCE.

THERE are times when the amount of oil fed to the motor should be increased or decreased. After an overhaul of the power plant and the bearings have been taken up, it is important that the lubricator be set to supply a larger amount of oil than normally. After the bearings have become worked in the amount may be cut down. Lubricators are adjusted easily if one understands the principle of operation. That shown in the accompanying illustration is of the mechanical type, a cam raising and lowering a plunger, which forces the oil past a check valve to the working parts. As the amount of lubricant forced depends upon the stroke of the plunger, this member is made adjustable.



Adjusting Mechanical Lubricator.

The variation of the stroke is accomplished by restricting or increasing the movement of the yoke member, and an adjusting nut secured by a lock nut is provided for this purpose. To decrease the amount of oil the adjusting nut is screwed down, diminishing the quantity of lubricant, while raising or lengthening the stroke increases the amount.

This type of oiler is very efficient and the only trouble likely to be experienced is through clogging of the feed pipes. This can be avoided, however, by using a clean oil, one free from foreign elements. A clogged pipe is indicated by the plunger remaining up or stationary. The obstructions can sometimes be removed by operating the plunger by hand. When the oiler is set temporarily to increase the amount of lubricant, in cutting down the quantity, care should be taken to make the adjustment so that the proper level will be maintained in the crankcase. This can be determined by a little experience.

REMETALLING BEARINGS.

The remetalling of bearings is a job which requires care if satisfactory results are to be obtained. In an accompanying illustration is presented a suggestion for a jig, which is said to prevent blow holes and to provide a smooth bearing surface. It comprises a stiff iron plate of suitable dimensions and drilled to receive the stud member. The clamp, which is shaped to leave a space for the pouring of the metal between the inner side of the bearing and the tube, is secured to the stud as shown.

Between the edges of the brasses are placed graphited tin strips secured by a clip. To prevent leakage of the molten metal from the bottom a piece of asbestos packing is utilized. This arrangement permits of metalling a pair of brasses at a time. If care be exercised in heating the brasses the old metal may be removed without injuring the tinned surfaces. It is important that there be a sufficient number of holes in the shell for securing the new lining in addition to the tinning.

LOCATING SMALL SCREWS.

Small screws, especially machine, are sometimes difficult to start, particularly when located in places not easily reached by the fingers. A small wire bent double at one end and slipped under the head of the screw will hold the latter steady while the threads are being caught. Another method is to cut a V slot in a small strip of tin. This plan is recommended because the device will take several sizes of screws. Still another suggestion is to take a piece of stiff paper and push the screw through it.

STRIPPING WIRES.

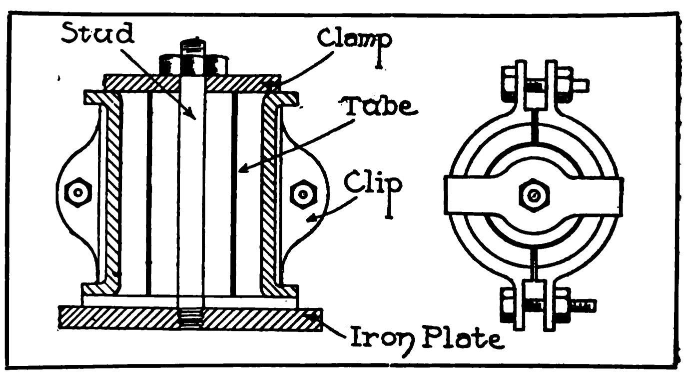
The usual practise in stripping insulation from ignition wires is to employ a knife. This results in more or less of the copper strands being cut, reducing their number. An excellent tool for this work is a clip, such as utilized for cutting the finger tails. One that has seen considerable service is best adapted for the purpose.

CARE OF OILY WASTE.

Oily waste and greasy cloths should not be allowed to accumulate in the garage unless stored in a suitable container, owing to the danger of spontaneous combustion.

HOME MADE PISTON CLAMP.

Replacing a piston in the cylinder requires care, as the rings are easily broken. While string may be utilized to compress the rings, a clamp made for this work is much superior and it also saves time and labor. A



Suggestion for a Jig for Metalling Brasses for Big End Bearings.

clamp may be made easily and at slight expense.

Assuming that the piston is 4.25 inches in diameter: Take a strip of band iron .125 inch thick, .5 inch wide and 16 long. Bend the metal into a circle and measure off 1.5 inches on each end, marking the distances. Place the ends in a vise and bend them over. This will provide extensions which may be gripped by the pliers when the clamp encircles the ring.

The band should be slightly less than 4.25 inches in diameter to compress the ring fully. To use the clamp, place it over the top ring and draw the ends of the band together with a pair of pliers while an assistant slips the cylinder over the head of the piston and ring. Upon the latter being caught the pliers may be released and the clamp used on the next ring and so on until the work is completed.

FEATURES OF KELLAWAY KEROSENE CARBURETOR.

A GASOLINE-KEROSENE carburetor of ingenious design, one permitting the use of either liquid or both together, is the Kellaway, a description of which appears in a recent issue of Motor Traction, an English print. Among the advantages noted in the Kellaway is that the butterfly throttle valve is eliminated, the throttle being placed on the atmospheric side of the vaporizer. Some authorities on heavy fuel carburetors hold that the desired finely sprayed fuel is not obtained with the butterfly throttle valve, particularly at low motor speeds; that it does not make for complete and effective pulverization of the fuel.

The Kellaway design, an elevation and sectional view of which are presented at Fig. 1, may be said to be of the rising air valve and fuel control needle type. When the air valve rises from its seat pure air can enter the motor, but when seated all air must pass through special ports up and down concentric tubes and past the fuel jet, which, being of special design, admits either unmixed or mixed fuels, according to the position of the taper needle valve. Details of the fuel valve, which is controlled from the seat, are presented in the illustrations and a little study should enable the reader to understand its action.

The main body of the vaporizer A has a domed cover, retained by wing nuts, making for accessibility. On the left is an extension of the body whereby the carburetor is connected by a suitable union to the intake pipe or manifold of the motor. Fitted into a recess in the body casting is B, a cylinder bored in two diameters, and sliding in this is a piston C, to which is secured by a lock nut the air control valve D. The method whereby a dash pot action is secured is illustrated in the drawings. From the upper end of the piston, conveniently secured by a spring and bayonet joint, as indicated, depends a rod E, at the lower end of which, attached by a tee joint, is F, the fuel control needle, which is parallel, and a sliding fit in the nozzle piece G. The last named has a recess H bored in it. J is the fuel inlet for gasoline and K for kerosene. It will be seen that the recess H communicates with the fuel inlet J, and that K conducts to a well L, into which dips the end of the fuel control needle, having at M a taper slot.

The general effect of this arrangement is that, while gasoline can pass from the inlet J through the ports indicated into the recess H, and upward around the helical channel indicated as cut around the fuel control needle F, and emerge at the jet nozzle N, the kerosene cannot make its way to the recess H until the air valve rises, taking with it the needle, and so allowing the heavy fuel to pass by the way of the taper slot M. A plug, as shown, closes the well.

Around the cylinder B are small drilled holes O, and above the lock nut that secures the air valve are, in the piston, larger taper holes P. Encircling the body casting is a sleeve type throttle valve Q, having specially shaped air holes R in it, and registering with similar holes in the body casting. Concentric tubes S and T surround the fuel control device, as shown in black in the drawings, the former fixed at its lowest end to the body casting, and the other, by its upper end, to the rising piston. It will be seen that air can pass through the holes R in the throttle valve, through

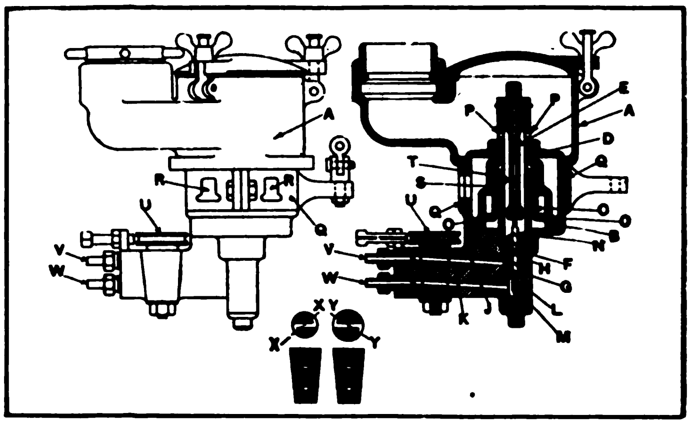


Fig. 1—Elevation and Sectional View of Kellaway Bi-Buel Carburetor in Which the Usual Butterfly Throttle Valve Is Replaced by a Sleeve Type and in the Atmospheric Body.

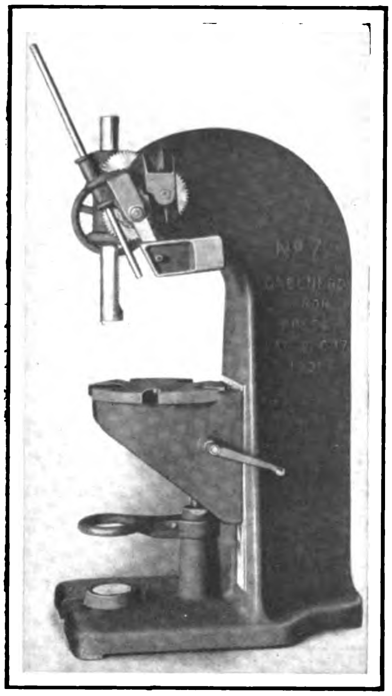
the holes O, up around the outside of the tube S, down between the two tubes and up past the jet nozzle, and finally out through holes P into the induction pipe. The space under the domed cover is practically the mixing chamber.

The conical valve V controls the liquid entering, as to gasoline by the connection V, and kerosene by the connection W. The valve is operated by a wire control passing around the grooved pulley and guides, the lead being conducted to a quadrant on the dash. Below the sectional drawing are shown two horizontal sections of the conical valve, with vertical sections respectively cutting on lines X X and Y Y. The holes, channels, etc., are so cut and arranged that by operating the valve either gasoline or kerosene or a mixture of the fuels may be utilized. The annular space between the lower end of the tube S and the jet nozzle forms a well that may be flooded with gasoline which is used for starting purposes.

GARAGE AND SERVICE STATION EQUIPMENT.

PORTABLE, mechanical tire pumps are a valuable addition to the garage and service station, as they may be utilized for cleaning purposes as well as for inflating tires. The Taylor Manufacturing Company, West 14th street and 48th avenue, Chicago, is marketing a compact electrical outfit which is shown in an accompanying illustration. The pump proper is driven by a .25 horsepower motor which is constructed either for direct or alternating current and for varying voltages.



No. 7 Greenerd Arbor Press, Taking a Diameter of 36 Inches and Providing a Pressure of 25 Tons.

The outfit is mounted on an oak base and may be moved easily about the garage, it rolling on four heavy steel casters. A looped steel handle is provided, making for convenience. The motor is mounted beside the pump and drive from the former is by means of steel pinions and cast iron gears. The equipment is very complete, including 15 feet of high grade flexible hose with connections and pressure gauge and 15 feet of electric wiring and socket.

The pump itself is known as the Noil, so named because its operation precludes all possibility of lubricant or oily vapors being carried into the inner tube with the air when inflating. The pump works on the plunger-diaphragm principle, and it is held that frictional heat is eliminated. It is 7.5 inches high, weighs 6.5 pounds and employs no leather cups, etc.

The crankcase is of aluminum, and gears and plunger of solid bronze. The plunger is specially constructed and it is held that it will withstand a pressure of 1000 pounds. Among the qualities claimed for the Noil are that it will deliver a steady flow of air and that it will supply from 90 to 150 pounds at low speeds.

NO. 7 GREENERD ARBOR PRESS.

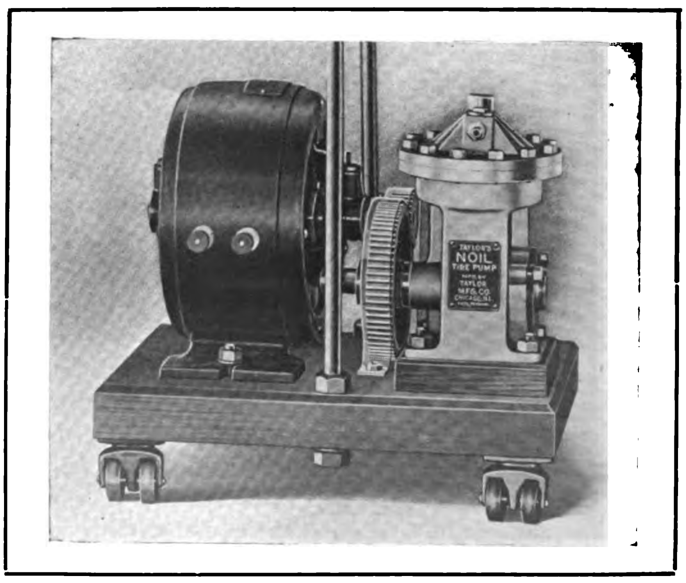
Arbor presses are utilized for a number of purposes in the repair shop and service station and included in the work these machines accomplish is the straightening of rear axles, etc. Edwin E. Bartlett, 330 A street, Boston, manufactures a wide variety of Greenerd arbor presses and in an accompanying illustration is shown the No. 7, one of the largest of this type produced by the concern. It takes a diameter of 36 inches and has a leverage of 250:1, and a pressure of 25 tons is obtained easily. No change in principle or design has been made from the well known No. 5 Greenerd machine except in size and capacity. When the lever is in the position indicated in the illustration, the rack or ram may easily be moved up or down by means of the hand wheel.

The knee is operated by the crank shown, revolving a screw through a pair of mitre gears. This screw runs in a nut in the base. The design is such that the knee can be lowered to its extreme position without the screw reaching the floor, making it possible to place the press in any position without cutting the floor for the screw. The knee is held to the frame by two studs and nuts, the nuts being adjusted and locked so that the knee can be moved easily. The pitch of the elevating screw is such that these nuts do not require tightening to hold the knee under heavy pressure.

The No. 15 Greenerd is especially adaptable to automobile repair shops and has advantages over the No. 3.5, 4 and 5 sizes in that the capacity is 36 inches between the uprights and the opening under the revolving plate is 10 inches. One man can obtain seven tons, while two can secure 10 tons pressure. The maker is issuing a circular on arbor presses giving complete details, which will be mailed upon request.

FISHER QUICK ACTING VISE.

Fisher & Norris, Trenton, N. J., is manufacturing what is known as the Fisher quick acting lever vise. It is constructed of gun metal with a solid bar and all parts are interchangeable. The work is inserted in the jaws and held securely by a forward movement



Taylor Noil Portable Garage Tire Pump, a Compact Unit Operated by Electricity.

of the lever. The part cannot be removed until the lever is pushed back. The jaws are faced with steel, file-cut and properly tempered.

CORRESPONDENCE WITH THE READER.

Motor Efficiency.

(38)—Having purchased and converted a pleasure car into a light truck, we find that it does not develop the power it should. A motor expert states that the valves are too small and should be enlarged, as well as a number of other conditions. Is there any method, and one not involving too much expense, whereby the valves could be improved? INFORMATION.
Lockport, N. Y., July 10.

The efficiency of some types of old motors may be increased by alterations, such as reboring, enlarging the valves, etc., but it is not advisable to undertake too many changes owing to the expense involved.

It is not always possible to fit larger valves, but alterations may be made to improve their efficiency. Herewith are presented suggestions of this nature, the sketch at A showing how an improvement may be made to the inlet member. The same size valve is retained, but the port area has been increased by cutting away a portion of the seating, the metal removed being denoted by the shaded sections. This reduces the obstruction to the incoming gas very materially.

At B is presented a sketch showing how the outline of an inlet may be improved and brought nearer the stream line shape. In order to give the incoming gas a flow as easy as possible, a part of the underside of the inlet valve is removed. This portion of the valve requires the most treatment, leaving only a conical face for the proper seating. The exhaust valve could be treated similarly by cutting away the metal as shown at A and enlarging the port area.

Suggested Oil Gauge.

(39)—I am bothered by my model T Ford motor smoking excessively, although the instructions of the agent are followed carefully. Although the engine is equipped with an oil gauge of the type sold for this purpose, it is difficult to note the level of the oil unless you stoop under the fenders, and many times the glass is so covered with dirt that the oil cannot be seen. Is there any gauge made to show the height of the oil without these annoyances? A. W. D.
Indianapolis, Ind., July 5.

The A. C. Danver Company, Providence, R. I., is marketing a special oiler for the car mentioned which is said to eliminate undue smoking and which has a gauge so mounted and located that it is an easy matter to note the height of the lubricant in the crankcase.

Adjusting Schebler Carburetor.

(40)—Can you give me any information as to the cause of my not being able to set a Schebler carburetor so as to obtain a smooth running motor, when throttled down, and power at high speeds? If the carburetor is set so as to start easy and throttle, the mixture is too rich at a high speed. I have changed the position of the arm on the dial, also the air valve and the needles, but do not get results. A. K. S.
Worcester, Mass., July 21.

The failure to obtain the desired results or flexibility at all motor speeds would indicate the presence of auxiliary air, as the mixture is too rich when the throttle is opened. It should be remembered that the needle valve is lifted by a cam, increasing the supply of fuel. The writer recalls a similar instance where the trouble was found to be worn valve stems. The space was such that considerable air was admitted at low speed, compelling the use of more fuel than could be successfully vaporized at higher speeds. The effect of auxiliary air is more pronounced at slow motor speeds than at high when there is greater or steadier suction. Examine the valve stems, intake manifold and connection between the latter and the carburetor.

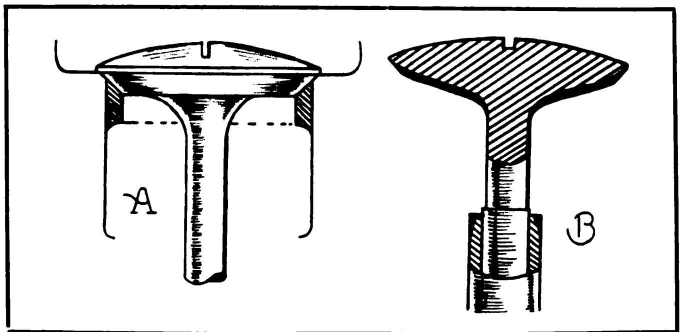
Bi-Fuel Carburetors.

(41)—What is the meaning of bi-fuel? I note reference made to it in a motoring print. Is it a combination of two fuels in a carburetor, and if so how is it brought about? DRIVER.
Toledo, O., July 3.

By bi-fuel is meant two fuels. In a number of carburetors designed to utilize heavy fuels, provision is made for the use of gasoline for starting, after which kerosene is utilized. Some types can use either gasoline or kerosene independently or together. Elsewhere in this issue will be found an article on heavy fuel carburetors which explains their action.

Gear Shifting Troubles.

(42)—We have a converted pleasure vehicle with a cone clutch which we utilize in our business and the driver complains he has trouble in changing from one speed to another. We have had to renew some gears in the transmission presumably because of the trouble, although the gears were worn when we purchased the machine. What causes the trouble and how may it be overcome? SUBSCRIBER.
Utica, N. Y., July 19.



Increasing Efficiency of Motor: A, Showing How Valve Port Area May Be Increased by Cutting Away a Portion of the Seating; B, Improving Outline of Inlet Valve, the Solid Black Portions Representing the Metal Eliminated.

It is evident that the inertia of the flywheel is not overcome; that is, the clutch shaft spins after releasing the clutch, making it difficult to mesh the gears. The trouble may be overcome by fitting a clutch stop or brake. This is secured to a cross member or transmission casing and when the male portion of the clutch is withdrawn it comes in contact with the stop, checking the rotation of the wheel. The method of constructing and fitting clutch stops was described in a recent issue of MOTOR TRUCK.

A. F. Mais has resigned as consulting engineer of the Studebaker Corporation and will take a rest before associating himself with another well known concern. Mr. Mais designed two Studebaker trucks, which were exhibited at New York last winter and which have been thoroughly tested and developed. These machines have not been produced commercially because of the need of all the factory facilities for producing passenger cars. They were of the internal gear driven type. Mr. Mais also designed the Mais truck, built by the Mais Motor Truck Company, Indianapolis, Ind.

THE A B C OF MOTOR TRUCK IGNITION.

Part XII---Explaining the Method of Collecting Current Obtained with the Magneto and Its Distribution to the Spark Plugs---Construction of Distributor Components and How the Spark Is Timed.

By C. P. Shattuck.

HAVING explained the generation of the primary current and its interruption by the mechanism of the circuit breaker, the transformation of the low

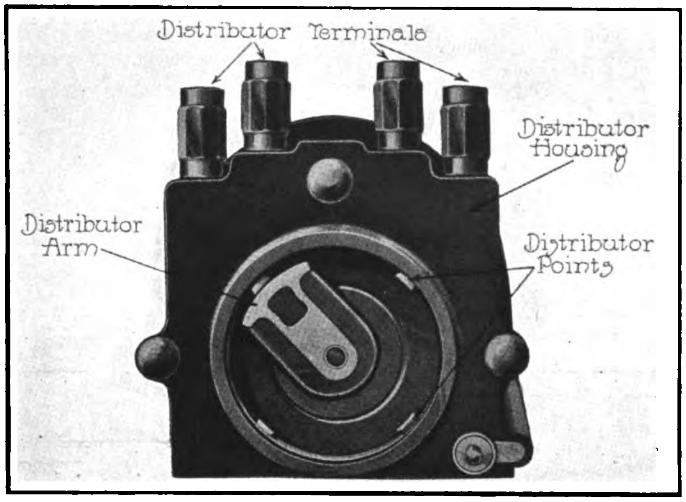


Fig. 60—Components Utilized in Distributing the High-Tension Current in the Remy Inductor Type of Magneto.

voltage current into high and its distribution to the spark plugs of the motor cylinders is next in order. While the construction of magnetos will vary in some respects, in that in some the winding is stationary, while in others it rotates, the method of current production may be said to be practically the same.

Before discussing the collection and distribution of the current generated the different types of magnetos will be defined. The term high-tension is generally utilized and is somewhat misleading to the novice. Although a high-tension current is obtained ultimately in some types, it is secured through the utilization of a transformer coil, while with others the building-up of the primary circuit is by means of a secondary winding contained within the instrument itself.

Magnetos Defined.

With the latter, or true high-tension type, the coil is eliminated, also a number of wires necessary with the other system. That the true high-tension instrument makes for simplicity is apparent when it is considered that in addition to the leads to the spark plugs, it requires only one other wire, that employed to ground the primary current, or in other words, to cut out the secondary current. This connection from the breaker box to the switch, thence to ground, differs from the battery and coil ignition in that the circuit is open when the use of the magneto is desired, while with the other system the circuit must be closed or completed to obtain operation. The open and closed types of switches utilized with the various magnetos will be explained in logical sequence.

With the low-tension magneto, so designated in this discussion to prevent confusing the reader, the primary current is collected and led to a transformer coil, where it is built up or strengthened, returning to the magneto, where it is distributed to the proper spark plug. The makers of both types advance able arguments in behalf of their product and their claims will be presented in the discussions of the different designs.

Magnetos utilized for ignition may also be classified in two groups, according to the basic principles employed in the magnetic field to produce the primary current, these being known as the armature and the inductor types. The armature type may be subdivided into two classes, simple and compound, the former including those designs which utilize a transformer coil, and the latter a double winding, or the true high-tension instrument. With the armature type the wire is wound around the core, and as the construction rotates between the pole pieces of the magnets the electrical impulses are set up within the winding. The primary current is collected from the armature by collector rings, brushes, etc.

The inductor type of magneto differs very materially. With this design the winding is held stationary between the pole pieces, on either side of which revolves a steel inductor. The construction eliminates brushes, collector rings, etc., and the manufacturer lays great emphasis on the design, pointing out that it is not only rugged, but makes for simplicity as well. With the inductor type of magneto it is possible

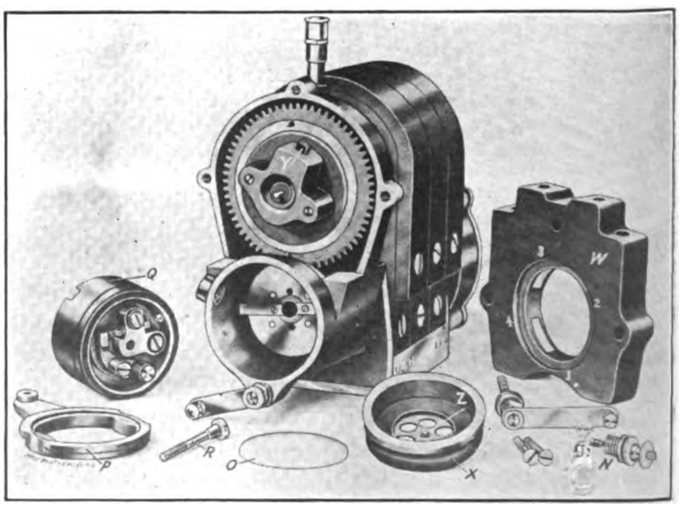

Fig. 61—Distributor End of U & H Magneto with Distributor Housing Removed to Illustrate Method of Assembly.

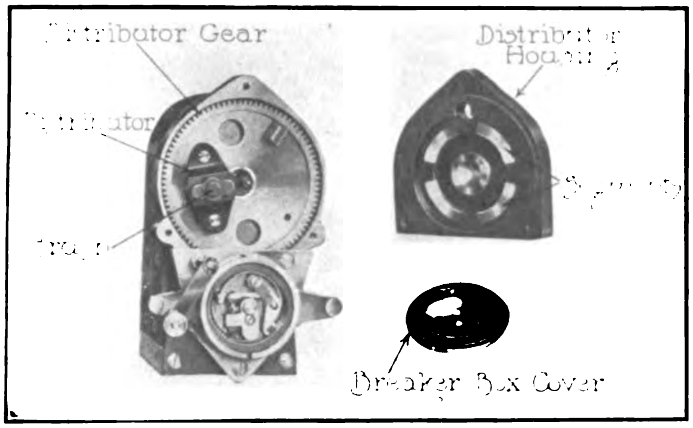

Fig. 62—Conventional Type of Magneto Employing a Wipe Contact—The Distributor Housing Is Displaced to Show the Segments.

to incorporate the secondary winding and obtain the same results as with the true high-tension instrument; in fact, when so arranged, it is a true high-tension.

Function of the Condenser.

Reference has been made to the condenser, a wiring plan of which was shown at Fig. 56 B. As previously explained, when an electric current flows through a wire it induces a current in any wire parallel to it. This is true in the case of two separate windings, as in the double windings of an armature, and it also applies to the various turns of the same winding. The action is termed self-induction, which has been previously discussed, taking place approximately when the primary circuit is broken by the make and break mechanism, and upon the current attaining its maximum value, or when the greatest number of lines of force is cut. Upon the separation of the contact points there is what may be termed an extra current over and above the initial impulse, and caused by self-induction. As a high electrical pressure exists when the contact points separate, considerable heat is present and the high temperature would soon burn away the platinum were it not for the condenser, the object of which is to prevent burning or to absorb the surplus energy of the spark.

Operation of Condenser.

It consists of two sets of tinfoil sheets, each insulated from the next, but connected to each alternate one. This places in compact form two large sheets of tinfoil separated from each other by a sheet of mica. One set of sheets is connected to one end of the primary and the second is fastened to the other end, the wires being continued to the make and break mechanism as shown at Fig. 56 B. This construction is termed parallel. When contact of the platinum points is broken, the current flows toward the gap, but as there is less resistance existing in its passage to and in the condenser, it is absorbed in this device. The energy is not lost, however, for when contact is re-established at the platinum points the current flows from the condenser, joining the newly generated electricity in the primary winding and adding to its strength. The principle of the condenser is similar to that of the induction coil which is utilized with the battery system of ignition.

The Distributor.

Irrespective of the method utilized to collect the current generated by the magneto, it is highly important that the transformed or induced electricity be properly distributed; that is, that the spark be produced at the gap of the spark plug when the piston of the cylinder has compressed the gas and is ready to begin the firing or impulse stroke. It has been pointed out that with a four-cycle, single-cylinder motor the points in the breaker box of a magneto separate only once in a complete revolution of the armature shaft. Consequently but one spark is obtained. With a four-cycle, four or six-cylinder engine it is essential that means be provided whereby the high-tension current will be distributed to the various plugs in the proper order.

The four-cylinder motor, for example, requires one spark for each cylinder for every two revolutions of the crankshaft, a total of four sparks. With the magneto, that is, the armature shaft, driven at crankshaft speed and with two interruptions of the primary circuit by the circuit breaker mechanism, it is obvious that only two sparks are obtained each revolution. As the crankshaft of the motor makes two complete revolutions, as does the armature of the magneto, it will be seen that it is necessary to utilize some means for obtaining a proper reduction between the armature shaft and the driven distributor, else the spark would not occur at the proper instant. This will readily be

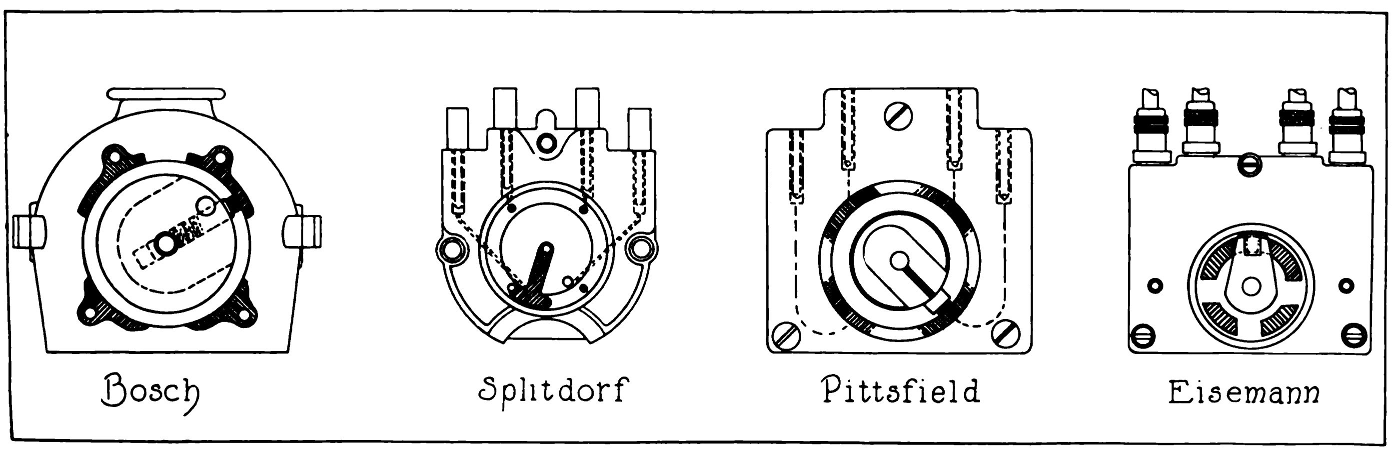

Fig. 63—Distributor Components of Conventional Types of Magnetos, also Connections Between Segments and Terminals.

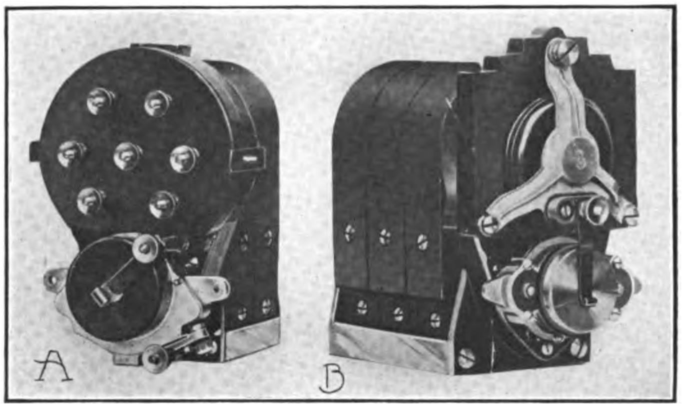

Fig. 64—Types of Bosch Magnetos: A, Six-Cylinder Unit with Terminals on Face of Distributor Housing; B, Four-Cylinder Instrument.

understood when the strokes of a four-cycle motor are taken into consideration.

The function of the distributor and its driving gears is that of properly distributing the high-tension impulses. While there are different forms, the principle involved is similar. By referring to Fig. 61, which shows the U & H magneto, with its distributor housing removed, it will be noted that there is incorporated a large gear, which meshes with a similar member secured on the armature shaft. These gears are in the ratio 2:1, or in other words, the large gear makes one complete revolution to two of the smaller member. Therefore, if the armature shaft makes two complete revolutions, the large gear will make but one. It is this arrangement that obtains the proper distribution of the high-tension current. Similar distributor gearing is employed with two, three and six-cylinder motors. The ratio of drive between the engine and the magneto, however, differs in two-cycle motors. As the relation of the speed of the crankshaft to that of the armature shaft has been explained, further comment is unnecessary.

The large distributor gear is of metal, usually brass or bronze, and attached to and revolving with it is the distributor arm, having a brush or similar construction, which makes contact with segments in the distributor housing. The number of segments corresponds to the number of cylinders, there being four for a four-cylinder motor, six for a six-cylinder, etc. The plate carrying the distributor gear is composed of hard rubber or compositions, non-conductors of electricity, to prevent the high-tension current from passing to any metal part of the magneto other than the segments. Particular attention is paid to the plate, etc., as the tendency of the secondary current is to flow where the least resistance is encountered.

Included in the distributor mechanism is the distributor housing, which is also a non-conductor of electricity. This housing is so made that it may be removed, the construction varying somewhat, but the principle being similar. It is secured to the body of the magneto by screws, clips or clamps, and imbedded in it are the metal segments of a circle. Secured to each of these is a wire or cable, which is led to a recess in which the distributor terminal is inserted. The connections between the segments and the terminals are shown at Fig. 63, the drawings also showing conventional types of distributors, distributor arms and bushes.

The construction of the distributor proper varies. In the U & H magneto shown at Fig. 61 the distributor arm is a brush, which makes contact with the metal segments imbedded in the member W. The Simms instrument illustrated at Fig. 62 utilizes a different arrangement, while the Remy, presented at Fig. 60, does not employ a wipe or brush contact. With this instrument the distributor arm is a triangular piece of brass molded in a material called Bakelite, a special composition noted for its high dielectric strength and non-hygroscopic qualities. The arm in revolving does not touch the small brass points in the housing, and it is pointed out that the construction increases the intensity of the spark, as well as eliminates opportunity for short circuits.

When contact is made between the brush of the distributor arm and a segment, or in the case of the Remy instrument, when the arm is opposite the brass point in the housing, the high-tension current flows through the metal and connection to the terminal, thence to the spark plug. It will be noted that the segments of the distributor are placed equidistant or 90 degrees apart with the four-cylinder unit and 60 degrees with the six, the number employed corresponding to cylinders of the motor. The different forms of distributor housings and methods of retention are shown in accompanying illustrations. Some of the improved types are presented, such as the Bosch at Fig. 66. In the perfection of the magneto the manufacturer has incorporated improved terminals and water and dust proof features, which will be discussed with the presentation of each type.

Safety Spark Gap.

With some types of magneto the true high-tension, for example, a device known as the safety gap is incorporated. It may be compared to the safety valve utilized with steam installations, which provides for the release of a portion of the steam when the pressure exceeds a predetermined amount. Owing to the char-

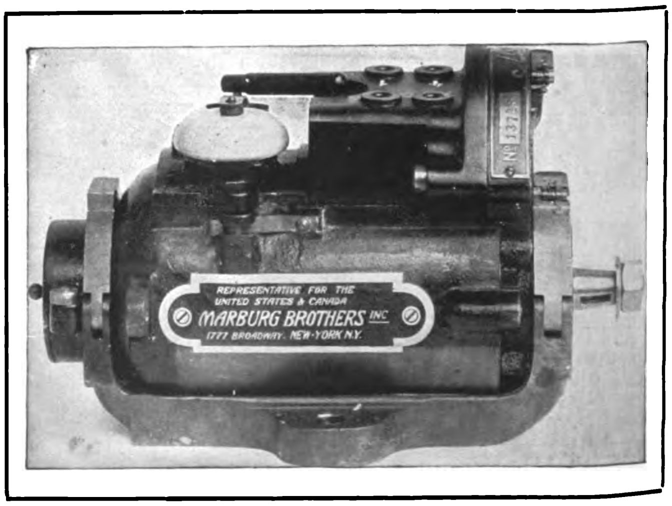

Fig. 65—Location of the Distributor Terminals of the Mea, Utilizing Bell Shaped Magnets.

acter of the high-tension or secondary current, if by chance a wire leading to a spark plug should become broken, the pressure of the electricity in the windings would be sufficient to break down the insulation in seeking a short path to ground.

The safety gap is employed to guard against damage from this cause, and as the name implies, comprises a space in a connection between the high-tension collecting brush and the ground represented by the metal housing of the magneto. As long as a current can pass over a gap having less resistance than that of the air space between the safety spark gap points, as in normal operation, the spark gap is inoperative. Should a wire become broken or disconnected at a plug, etc., and sufficient current be generated to damage the windings, the pressure is high enough to allow the energy to overcome the resistance of the air gap and pass to the ground. In order to prevent the ignition of any gasoline vapors that might be present in proximity to the magneto, the safety spark gap is enclosed in a small cage of wire gauze and is covered with a porcelain cap.

(To Be Continued.)

Ed. Note—The next installment will deal with the inductor type of magneto, outlining its components and operation, also presenting wiring diagrams.

REOS TRANSPORT NITROGLYCERINE.

Fleet of 12 Equipped with Specially Designed Bodies Readily Convertible When Desired.

The Independent Torpedo Company, Findlay, O., has placed in commission 12 Reo roadsters, made by the Reo Motor Car Company, Detroit, each of 20 horsepower, for delivering nitroglycerine. The explosive is carried in a detachable open body specially designed by the torpedo company for this specific purpose so as to admit of the machine being easily converted into a light and speedy car for their salesmen or official staff.

The fleet will cover Ohio, Indiana, Illinois, Kansas and Oklahoma, with possibly two or three other states adjoining this field. A large two-ton Reo motor truck is used an an auxiliary for hauling nitroglycerine from one factory to another.

HAULAGE COST 66.7 CENTS A TON.

Expense for Operating a Three-Ton KisselKar Truck in Packing House Service.

The Plankinton Packing Company, Milwaukee, Wis., has in its service a three-ton KisselKar truck, and a statement of the cost of operating it for the year ending June 10, 1913, shows that during that period the haulage expense was 66.7 cents a ton, figuring depreciation at 15 per cent. This estimates the life of the truck to be six years and eight months, or practically 20 months longer than the generally accepted term that a truck will be serviceable. Much, of course, depends upon the care and attention given.

In considering this statement it will be noted that the truck was worked 305 days out of 312 possible; that it was driven 7393 miles and carried 6,574,474 pounds, or approximately 3287 tons. The cost for labor, fuel, oil and supplies was 34.5 cents a ton; for repairs (including tires and the daily washing required by the government regulations), 11.2 cents a ton, and for interest, insurance and depreciation, 21 cents a ton. The truck carried each ton an average of 2.25 miles, and the average price of operation was 29 cents a mile. The subjoined statement is worthy of careful scrutiny:

Total number of possible days				312
Actual days worked				305
Miles				7,393
Weight handled, pounds				6,574,474
Power (fuel)	192.07		0.058	
	Total		A Ton	
Labor	$863.34		$0.263	
Power (fuel)	192.07		0.058	
Oil	50.06		0.015	
Supplies	28.09		0.009	
Total		$1133.56		$0.345
Engine repairs	$0.85		$0.000	
Transmission	2.50		0.001	
Tire repairs	214.08		0.065	
Other repairs	150.46		0.046	
Total		$367.89		$0.112
Interest and insurance	$239.72		$0.073	
Depreciation (15 per cent.)	449.80		0.137	
Total		$689.52		$0.210
Grand total		$2190.97		$0.667
Total number of hours				3044.75
Number of stops				4543
Pounds a stop				1447
Total number gallons fuel				1622.50
Miles a gallon				4.56
Cost a mile				$0.29
Total cost a day				$7.18
Miles a ton				2.25
Total number trips				1193

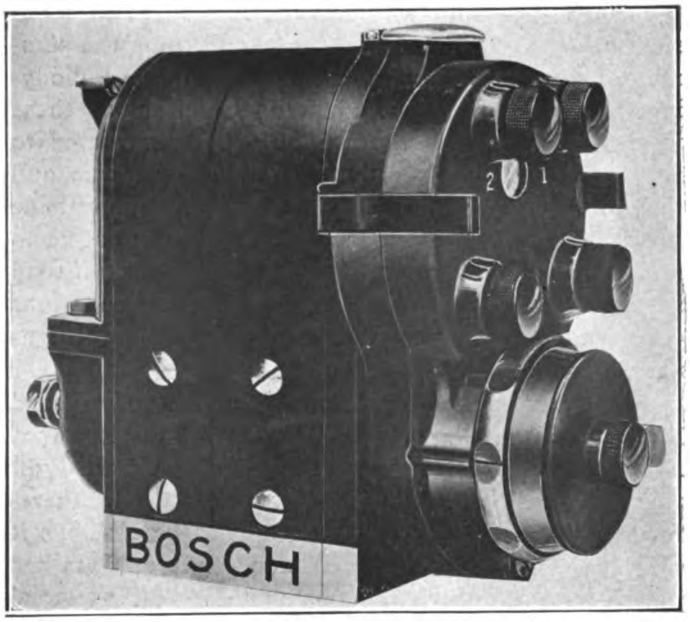

Fig. 66—Method of Retaining Distributor Housing of Bosch Having a Timing Window.

The item above under "other repairs" includes daily washing of truck required by government regulations at a cost of 35 cents a day.

INTERNATIONAL ROAD CONGRESS RESULTS.

MUCH time was devoted to subjects intimately connected with the use of motor vehicles at the third international road congress, which convened recently in London, England. The keynote may be said to have been sounded by Lloyd George of England in his speech of welcome, in which he referred to the revolution which has come about in the use of roads through the development of motor traffic. He did not think this a matter to be deplored, for the more communication was improved the less was spent on distribution, and the more was available for production. Bad roads, he declared, meant a horse taken away from the plow and attached to a cart.

Accredited delegates were present from 39 governments, representing practically every civilized country in the world. As is usual with such gatherings much of the business was transacted in sections and by subcommittees.

The first section was devoted largely to the consideration of reports from nations concerning the planning of new roads and streets, and resolutions embodying the suggestions were adopted. Chief among these were that new main roads should be constructed to pass outside rather than through cities and towns, and that the planning of main road communication outside towns should be undertaken at once, the initiative to rest with a central state authority. The subject of road surfacing also was taken up and recommendations covering wood block paving, and asphalt for bridges and easy gradients, were adopted.

The second section took up the matter of road lighting. It was decided that it was quite clear that as country villages and urban districts could not light the roads in a way adequate for modern traffic, therefore the user must carry his light with him. Thus it will be seen that the international road congress has placed its seal of approval on the subject of universal lighting, so-called. It also was decided that motor lights should be proportionate to the speed and should enable the driver to see an obstruction at least twice as far off as the distance in which his brakes could pull him up. Resolutions were adopted that in inhabited places the headlight should be limited to the illuminating power of an ordinary lamp, and that one color should be adopted as a danger signal.

The third section took up the question of highway administration. The reports from the different nations showed a greater tendency toward larger centralization. It was decided that the task of constructing roads should be placed in the hands of larger units than the local authority. A Belgian delegate advocated the state control of all roads, but the conclusion reached was that it was difficult to make one rule which would apply to all countries.

The business of the congress naturally covered a wide range, and it would prove impractical to review the entire proceedings here, were it possible to condense all the various reports and papers presented. The general principle of the following conclusions was approved:

1—The expenditure on the maintenance and improvement of (a) the roads which serve as main routes of communication between important places in any country or (b) the roads which are used mainly by long distance traffic, unless such expenditure is borne wholly out of national revenues under a system of state administration of roads (which system is practicable and suitable in the case of some roads in some countries), should be mainly paid out of the national revenues, whether or not such roads are locally administered and maintained, subject, where local administration prevails, to the supervision of a central government authority both as to efficiency and expenditure.

2—It is desirable to abolish, so far as possible, all tolls on public roads, but it is equitable that the owners of vehicles which, on account of their weight or weight combined with speed or any other exceptional circumstances connected with either the vehicle or the use of the road, cause special damage to roads beyond the wear and tear of the ordinary traffic of any district should be subject to special taxation, the proceeds of which should be earmarked for expenditure on roads.

3—Borrowing money for new road construction and for the periodic renewal of the surface coating of a road is consistent with sound financial principles, provided that the loan period in the case of loans for renewals is kept well within the life of the surface coating.

Another important point discussed was that dealing with the construction of macadam ways bound with tarry, bituminous or asphalted materials. This occupied much time and brought out many interesting details. The main decision reached was that it was important, both in the interests of the duration of the road and the comfort of the users, that repairs should be made immediately a defect showed itself. Concerning the main proposition, a Russian delegate suggested that a committee be appointed to investigate the various methods used in different parts of the world and report at the next congress.

In the matter of traffic regulations the following conclusions, as prepared by Lord Montagu of England, editor of The Car and an international motorist of note, were adopted after long discussion:

1—That all regulations for the control of road traffic should be based on the principle of allowing the speed practicable for each different kind of vehicle consistent with public safety, general convenience and the normal wear of the roads.

2—That regulations for the conduct of fast and slow traffic should be as few and simple as possible, and should be such as can and ought to be universally adhered to and enforced.

3—That in large cities there should be a traffic authority on whom should be charged the duty of studying and dealing with street traffic problems, the powers of such authority and the co-ordination of such powers with those of other public authorities being matters of detail which must be settled by public authorities on consideration of the circumstances and conditions of each large city.

4—That there should be ample provision of traffic controllers (such as the police in London) with adequate powers to regulate the traffic, not only at congested points, but throughout the course of crowded streets.

5—That having regard to the increased danger which is necessarily created by the conditions of modern traffic, it is important that drivers should be carefully and systematically trained, and that children should be specially taught how to provide against the dangers of the road.

6—That except where local circumstances render it absolutely necessary, no obstructions, such as lamp posts, tramway standards, etc., should be placed in the centre of the road, except necessary refuges for pedestrian crossing.

7—No obstruction of the public highway should be permitted either by vehicles standing unreasonably, or by things placed on the highway. Exception must, however, be made for depots required for the work of maintenance or repair of the road, and for work being carried out by duly authorized and competent authorities, but in every case all necessary steps must be taken to insure the safety of traffic.

8—That regulations for roads and traffic must aim at defining the rights, duties and responsibilities for each kind of traffic in order to avoid the causes of accidents and damage, and to insure the maximum of order and liberty.

MOTOR TRUCKS IN CONTRACTORS' USE.

High Efficiency of Machines Used by Hugh Nawn Construction Company in Building New Boston Subways—With Large Estimates for Operating, Economy Is Shown.

THE largest and most important work now in progress in Boston, and probably in New England, is the building of the four sections of the subway from Park street to the convergence of Beacon street and Commonwealth avenue, and the two sections of the Dorchester subway, which is projected from Summer street to Andrews square, the Hugh Nawn Construction Company having contracts for the six different jobs. The subways are additions to the system now utilized for rapid transit by electric railways, and are in every sense municipal work. The subways are authorized by legislation, and the engineering is done under the direction of the commissions having supervision of construction. The expense is borne by the city, and the subways, when completed, will be leased for long periods to the Boston Elevated Railroad Company, which now has leases of the other sections of the Boston subway system.

The Hugh Nawn Construction Company, and prior to the organization of that company the business conducted by Hugh Nawn, has been known to Bostonians for more than a generation, and the headquarters are at Maple street, Roxbury. This concern is a specialist in excavation and foundation work, and this may mean anything from the construction of a sea wall to the bed on which a skyscraper may be supported. The company has built but one structure, the Cambridge car house of the Boston Elevated Railroad, but all of its work aside from this has been practically on or beneath the surface of the ground. Very frequently the company will have contract to make excavation and put in the foundation up to or about the level of the grade, and from this point the work will be taken up by other contractors.

Seven-Ton Mack Truck Used by the Hugh Nawn Construction Company, Boston, Mass., in the Haulage of Crushed Stone and Sand.

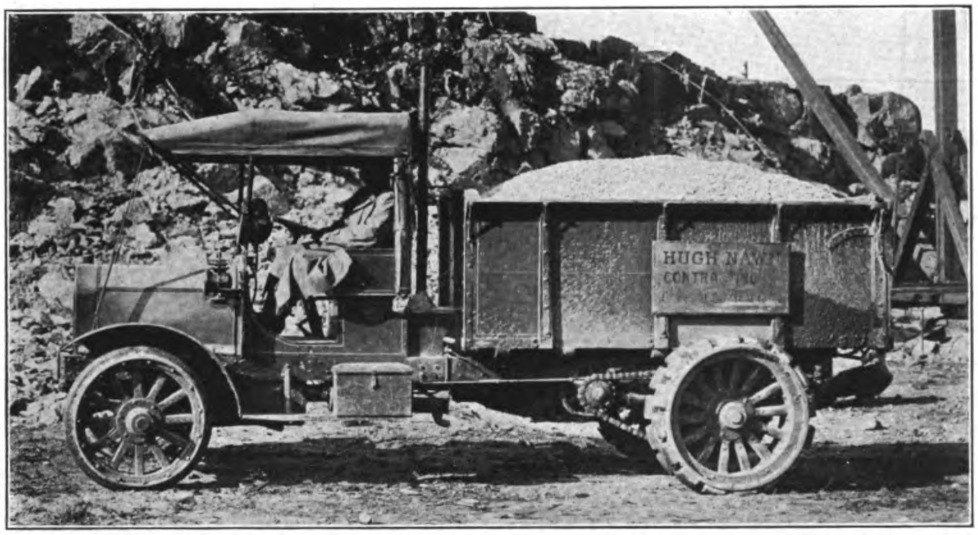
Emphasis is made of the character of work because it is essential that the company have transportation equipment of unusual capacity. The excavated rock and soil must be removed, even though a part of it is to be used later for filling, and all of the heavy stone and metal and the different materials utilized must be brought to the job. The company has need of large quantities of crushed stone for making concrete, which is very generally used in construction, and it has two stone crushers, the one at Dorchester and the other at Jamaica Plain, as well as a large gravel bank at Sharon Heights, Mass., about 15 miles from Boston, on the main line of the New Haven railroad. The resources are mentioned to demonstrate the proportions of the company. Just now it has about 400 men working on the two subway sections.

The subways are opened from the street, and the big trenches are sunk to the levels specified in the contracts, being dug to such depths as will insure solid foundation. That the traffic may not be impeded unnecessarily in the streets that are opened the trenches are bridged with timber of such strength as will support two-horse vehicles and loads, and the walls are protected from caving in by sheathing braced by timber. The subway structure itself is laid in the trench in the form of concrete that is made of crushed stone, sand and cement, and it is formed in molds, the sections being locked together at the joints by what may be described as dovetailing. When the structure has been completed the trench is filled to the level of the street grade, the earth consolidated and the paving relaid. This work is less expensive than tunnelling, and for the Boston subway system it gives every required result.

From the above brief description it will be understood that the amount of haulage necessary in connection with such a contract is very large. The Boylston street subway as projected is approximately 8000 feet long, and the Dorchester subway about 13,500 feet in length, or about 1.5 and 2.5 miles, respectively. All of the excavated rock and soil cannot be placed in the street and must be removed, the timber for the sheathing and bracing must be hauled, the materials for the concrete for the structure itself must be drawn and, after mixing, distributed along the work, and later the filling and paving is similarly transported. Were the

different contracts held by different concerns, work on all sections would be in progress simultaneously, and finally each would be joined, but as one company has the contract, so great a section of the city is not affected, for, incidentally, a great deal of temporary building has been necessary to provide for the street railways as well as the protection of the sewers, water mains, telephone and electric light conduits, and the like.

The little plaza at Copley square between Huntington avenue and Boylston and Dartmouth streets has been given over by the city to the company for use as a construction yard, and at this point has been erected a number of portable buildings, as well as a pair of mixing machines, by which the concrete for use in both subways is mixed. The work begins in Boylston street at 8 Monday morning and is continued without interruption until 5 Saturday afternoon, while in the Dorchester subway it never ceases. The two mixing machines, driven by portable steam engines, are whirling practically all the the time save from Saturday night until Monday morning, and every 24 hours approximately 500 tons of concrete is made and hauled.



Five-Ton Peerless Truck Loaded at the Stone-Crushing Plant of the Hugh Nawn Construction Company, Dorchester.

The stone is brought from the crushers and the sand from Dorchester, where it is received in cars from the Sharon sand bank, while the cement is brought in by the carload and is hauled to the yard. The company now has in service five trucks, four that it owns and one that it has hired, with the services of the man who owns it, and 25 two-horse teams and carts hauling stone, sand and cement, and it has other two-horse teams and carts and Watson dumping wagons hauling the cement and the excavated material.

The company has owned five trucks, the first being a three-ton White machine that was worked for 16 months and then sold because it did not have the capacity desired, and about a year ago three Mack trucks, one five-ton and the others seven tons, were bought. Eight months ago a five-ton Peerless machine was purchased, and these four are now in use. The hired truck is a five-ton Pierce-Arrow, which is driven by the owner.

The trucks were bought for two reasons, the one being that they could be used in the subway construction, and that the company does a considerable business in crushed stone which must be delivered. This is outside of its contracts. It was expected that the machines could be used to excellent advantage for stone haulage aside from work actually done on the subways, and while the purchase was impelled by the contracts they were bought with a view to service after these were completed. All of the machines are fitted with bodies that will hold approximately the capacity load of either sand or stone, and these have power hoists for quick discharging.

The round trip from the Dorchester crusher and the siding where the sand is received by railroad car to the Copley square yard is approximately nine miles, and it is about seven miles to the Jamaica Plain crusher and return. The trucks have averaged during the time they have been in service about 58 miles each day, carrying capacity loads half the distance.

All of these trucks are equipped with steel bodies, and as the loading and unloading is by gravity, comparatively little time is wasted at either end. This may be learned by analyzing the figures, which show that working 10 hours daily without stops the machines must make 5.8 miles an hour, and with an hour's allowance for loading and unloading this would give 6.44 miles an hour all of the nine hours they are on the road. Considering the hour specified, this would give three or four minutes at the yard and the crusher each trip, not unreasonable when it is understood that the horse wagons must be loaded and unloaded and congestion cannot be avoided, no matter how carefully the work is planned.

There are times, however, when the machines are worked from 14 to 15 hours each day, which would not be possible with any other form of transportation, and then the mileage accumulates very rapidly. Each of the seven-ton trucks makes in the ordinary day's work 58 miles, 29 miles loaded with seven tons, this being 203 ton-miles daily. This is an average of 7.25 miles to the round trip, or 3.62 miles loaded to the trip, or 25.375 ton-miles for the seven-ton trucks. The five-ton truck is driven the same distance and shows 145 ton-miles daily, this making 18.125 ton-miles for each trip.

It will be understood that the larger ton-mileage of the seven-ton machines shows striking proportions, in the aggregate, but this is to be expected

though the smaller truck is worked to its capacity constantly. Its work is stated as an average, and not with a purpose to make an unusual showing, yet in three weeks last November the Peerless truck was driven 1124 miles, an average of 63 daily, during which time it delivered from the crushers to the Copley square yard 1,590,010 pounds of stone, an average of 88,333 pounds a day. The working time for the day was nine hours and 30 minutes and the average speed was 6.66 miles an hour, including stops.

In arriving at cost figures it may be explained that Harry Nawn, who has charge of the transportation for the company, states that he has placed his estimates for truck expense high. He maintains that $20 a day assumed for the company's equipment is a not unreasonable cost for a seven-ton truck, and he has applied this to both the seven and the five-ton machines. He figures depreciation at 20 per cent. of the cost price annually, so that five years wipes out the entire investment. He estimates that the five-ton truck is equal to three pairs of horses, and the seven-ton truck equal to more than three pairs of animals.

Taking $20 as the daily cost and the average of 203 ton-miles for the seven-ton machine, it will be seen that the cost is 9.82 cents a ton-mile, and taking the five-ton machine on the same basis, the cost is 13.76 cents a ton-mile. But it is exceedingly probable that these figures will be somewhat reduced by a careful consideration of the factors.

Mr. Nawn says that his horses cost him, for a two-horse team, cart and driver, $4.92 a day, which is apparently a very low figure, but this can be attributed to the fact that the overhead is exceedingly small, the matter of appearance is not thought of, and the equipment is relatively large. The horses are generally first-rate animals, always large, and are kept in condition to do hard work, but they are not worked the entire year round as a rule, and have opportunity to recuperate during the winter months, from January until April there being comparatively little done in outdoor construction. The stables are located where the cost is relatively small, the administration and maintenance charges are minimized, and the expenses generally are low. It will be seen that with an allowance of $2 a day for a driver, $2 a day for stabling, feed, bedding, shoeing, veterinary service, supplies, etc., this leaves 92 cents for depreciation, insurance, taxes, repairs, administration and other expenses that may be incurred.

The prevailing price for a hired two-horse team, cart and the services of a driver in Boston and vicinity is $6 a day, and as this is expected to cover all expense and leave a reasonable margin of profit for the owner it will be seen that the difference of $1.08 between that and the cost to the Nawn company is 21.95 per cent., which is not large.

Relative to the cost of $20 a day for a machine, this is approximately 33 per cent. more than is fixed by general acceptance, and while it may be maintained that this is excessive and does not fairly represent the productiveness of the machine, it will also be admitted that with this as a basis of judgment there is no probability of any expense not being provided for. Mr. Nawn makes the statement that there is comparatively little difference between the cost of the five and the seven-ton machines, but this is seemingly paradoxical, for there will be variance with reference to investment, depreciation, interest, insurance, taxes, fuel, oil and tire cost, as well as garage and maintenance expense. It is true that the wages of the drivers will vary but little, and relatively the smaller vehicle ought not to be as productive as the larger, but this ought to be somewhat equalized by the greater speed of the machine. In the three weeks' work instanced it will be seen that the five-ton truck made an average of 63 miles daily, and it carried 44 tons daily, this during a working day of 9.5 hours. Placing this against the average, it will be seen that the cost a ton haulage was considerably reduced.

The Pierce-Arrow Five-Ton Truck Rented by the Hugh Nawn Company and Used for the Cartage of Cement—This Machine Has Carried 120 Tons .75 Mile in Less Than 10 Hours.

The round trip to the Dorchester crusher is nine miles, and to the Jamaica Plain crusher seven, and two round trips are practically as much as a team of horses can do. Taking a horse load as five tons, which is probably more than the average, two trips to Jamaica Plain would be 14 miles, one trip to each yard would be 16 miles, and two trips to Dorchester would be 18 miles. First taking the horse teams and allowing them five-ton loads, the cost for hauling two Jamaica Plain trips would be at $4.92 daily 70.3 cents a mile, loaded, or 35.14 cents a mile for the round trip for 14 miles a day. Making one trip to each of the crushers would cost 61.5 cents a mile loaded, or 30.75

cents for the round trip of 16 miles, and making two trips to Dorchester would cost 54.6 cents a mile loaded, or 27.33 cents a mile for the round trip of 18 miles.

The trucks make eight trips a day, which is assumedly to Jamaica Plain, and allowing the cost to be $20 a day for each machine, this gives a mileage expense of 68.9 cents a mile loaded, or 34.48 cents for the round trip of 14 miles. Taking the three seven-ton trucks, however, it will be seen that the actual cost of hauling a load is 24.62 cents a mile, considering the greater capacity. In other words, where the trucks are rated as having the same cost and both sizes can haul a full load for 68.9 cents a mile, the actual expense, based on the cost of the five-ton machine, is materially less for the seven-ton vehicles, as their load is 40 per cent. more. That is to say, that with a cost of 68.9 cents a mile for 29 miles a day, carrying a load of seven tons, the ton-mile expense for the larger trucks is 9.82 cents, and carrying a load of five tons the ton-mile expense for the small truck is 13.76 cents. Taking the teams with the hauls of seven, eight and nine miles loaded the cost is, respectively, 14.06, 12.30 and 10.93 cents a ton-mile. The figures as to mileage, however, show that trucks each are driven practically four times the mileage of the horse teams, and seemingly each does work equal to four teams, at least so far as mileage is concerned, with at least equal tonnage. On this basis the estimate of expense would appear to be four times the cost of a horse team, which is $19.68. The capacity of four teams, however, in this work, is 40 tons of sand or stone a day, which is equalled by the small truck, and exceeded by 16 tons, or 40 per cent., by the larger trucks. Regarded from this angle it would appear there is an element of economy that is not apparent from the bald statement of $20 a day cost, and being equal to three pairs of horses. Incidentally it may be stated that no valuation is placed on the reserve capacity of the trucks, which might in the event of need be worked constantly with changes of drivers.

The company has its own garage, which was built for storing the machines, and it is well equipped and has the conveniences and facilities that are essential to good attention. When the trucks were purchased a mechanic was employed to do all mechanical work necessary on them, including adjustments, replacements and repairs, to generally maintain them and keep them in condition for service, but this was not regarded as satisfactory, so a change was made. Instead of having the drivers simply qualified for driving the trucks, men who have had mechanical experience are hired, it being understood that their duty is to drive the number of hours the machines are worked, and after working hours they are expected to do whatever minor mechanical work may be necessary. That is, these men do practically all the ordinary work, making adjustments, ordinary replacements, as well as keeping the machines cleaned, oiled, greased, and replenishing the fuel, water and lubricant. One of these men is more experienced than the others and he is required to supervise whatever work is performed on the machines.

These men work evenings and Sundays on the trucks, receiving pay for whatever time is given over to maintenance work, while once a week the machines are thoroughly inspected by experts from the service departments of the makers of the trucks. By this system the trucks are kept in excellent condition and their efficiency is assured. In the event of work being needed that cannot be done by the drivers, the machines are sent to the service stations of the builders and there whatever is necessary is done by men familiar with them, who can be regarded as experts.

The company, besides its own work, supplies customers with crushed stone and sand within a radius of approximately six miles, although under some circumstances delivery might be made a greater distance. The company, by operating its own crushers, makes the profit that would be made by a stone dealer did it purchase its material, and the surplus, after its own needs are supplies, is distributed. It is used for construction, road building and landscape work, and its use is becoming more general every day. For this delivery the trucks have distinct advantage over horses, especially where the needs are urgent, and can afford much better service. In this respect they are a convenience and serve a decidedly useful purpose, eliminating the element of expense entirely.

The hired Pierce-Arrow truck in the service of the Hugh Nawn Construction Company has a crew of two men, and this is used exclusively to haul cement in bags from a railroad yard to the construction yard at Copley square, a distance of .75 mile. The crew load the truck at the railroad yard, but it is unloaded by a gang of helpers at the end of the trip. The truck has a platform body and quick loading and unloading is not possible; that is, gravity handling. As the cement must be taken from the cars and piled on the truck, and it is removed from the truck and stacked in sheds in the construction yard, time is required at either end of the trip. In the event of rain more time is required, as the cement must be protected from water. An example of the efficiency of this machine may be seen in the work of one day, when 24 loads of 100 bags, each bag weighing 100 pounds, were carried from the railroad yard to Copley square, this being a total of 120 tons. The time required was 10 hours, and the mileage was 36. Allowing approximately seven minutes for the run in either direction and seven minutes for loading and four minutes for unloading, this will account for every minute of the 10 hours of a day. The speed stated would be approximately 6.66 miles an hour which is probably about correct.

The owner of this machine keeps it in a public garage and gives it his own attention, so that it is not only well cared for, but it is not out of service. He has had a wide experience with trucks, and he drives, and insists upon those who are employed by him driving, with care. With him the machine is an investment, and upon its serviceability depends entirely his busi-

ness. He has owned other trucks and has learned by experience the better method of insuring productiveness.

Relative to tires, it should be stated that the trucks of the Nawn company are large size, seven-inch band tires being used on the forward wheels of the seven-ton trucks and seven-inch dual block tires on the rear wheels. These tires are guaranteed for 8000 miles, and they are giving very close to that mileage, generally somewhat in excess, with the rear shoes, while the forward tires will ordinarily yield considerably more than the guarantee. The fact that the tires are larger than are customarily used on such machines is the reason why satisfaction is given, while the machines are seldom, if ever, overloaded.

It may be pointed out in connection with this work that as the hauls are comparatively long, both horses and trucks each relatively make good showings, and as the loading and unloading is by gravity that the only advantage of the machines is their superior speed, greater reserve and larger capacity.

MAKING NITROGLYCERINE SAFE.

Special Equipment Fitted to White Wagon for Use in Oklahoma Oil Fields.

Handling high explosives is always dangerous, and transporting them by road vehicle may be regarded as being as great a risk for the driver as for the workmen using them, so when the Eastern Torpedo Company, Battlesville, Okla., decided to purchase a 1500-pound White wagon for delivery purposes it was necessary that the machine be specially adapted for the work. The company distributes nitroglycerine within a radius of 50 miles in the Oklahoma oil fields and the roads in many instances are to almost inaccessible places. There is very little of the highways that would be regarded as good, and the greater part can be very reasonably classed as rough cart paths.

The chassis was fitted with "soft" springs that are intended to be particularly easy in action and absorb the road shock, and pneumatic tires. The body is a special construction throughout. Crosswise and lengthwise of the frame are sills of heavy, long-leaf yellow pine that cover the entire loading space, and on this is built the compartment. First is a floor and then a layer of asbestos covered with a solid floor of pine. On this floor is a rubber mat, and on the mat is a copper pan with sides five inches in height. The asbestos is to prevent heat from the engine, exhaust pipe or muffler reaching the load, the rubber mat minimizes the shocks, and the copper pan is to retain the fluid and prevent its escape to the chassis should a can leak. The compartment is divided into 30 spaces seven inches square and 17 inches deep by poplar boards dovetailed together, and these are covered by a top in two sections, hinged at the front and rear, that can be locked at the centre. The body is 47.5 inches length, and back of this is a deck on which can be carried the reels for lowering the cans into the wells.

The loading and unloading may be done by the driver alone, and to facilitate handling by one man the right rear fender immediately above the wheel is made a step and running board on which the cans of explosive may be placed so that the driver may jump off unincumbered and without danger of jarring the can.

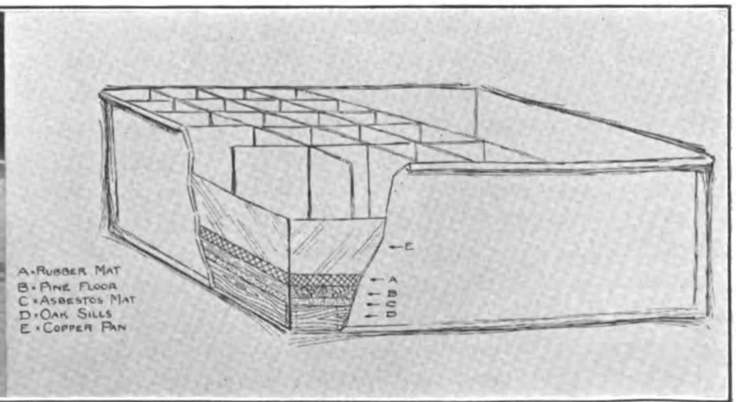
PACKARD AS STORE 'BUS.

Detroit Department Store Inaugurates New Service for Benefit of Its Patrons.

An innovation in progressive department store management in Detroit has been inaugurated by the Elliott-Taylor-Woolfenden Company of that city, which has established a free motor 'bus line from the Campus Martius, the main traffic centre of the city, to the store, half a mile distant, for the benefit of its patrons. Round trips are made on 15-minute schedule during shopping hours.

The vehicle consists of a Packard two-ton truck chassis equipped with a special 'bus body. Two rows of seats with a centre passageway provide for 22 persons. The interior finish is mahogany with dark green leather upholstered seats. The special equipment includes interior electric lights and cushion tires.

The 1500-Pound White Wagons in the Service of the Eastern Torpedo Company, Bartlesville, Okla.



The Special Body Designed for Use in Transporting Nitroglycerine in the Oil Fields of Oklahoma.

COAL DELIVERY BY MOTOR TRUCKS.

Careful Experiment Now Making by Metropolitan Coal Company of Boston, Largest Concern of the Kind in New England, to Determine Economy of Machines.

MUCH interest is manifested in the use the Metropolitan Coal Company, which is the largest coal dealer in Boston, and probably in New England, is making with electric vehicles in its delivery service in Boston. This concern was established many years ago and its business has developed with a view to serving the people more generally than does any other company, there being yards located in different sections of the city. Some of these yards are at the water front, for practically all of the coal is received by water shipments, often by barge or vessel load, and the distribution is made from these yards by wagon. The company has necessarily a very large equipment, this including about 600 horses and many wagons and carts, the greater part of the vehicles being of the two-horse team type, which have a normal capacity of from 3.5 to four tons, and some single-horse wagons that have a capacity of about two tons.

The delivery outfit of the company represents a very large amount of money, for good horses, such as

One of the Five-Ton Eldridge Front-Wheel Driven Carts Used by the Metropolitan Coal Company, Boston, Mass.

are used for heavy haulage, cannot be purchased for less than $350 each, and each pair, with cart and harness, is worth an average of $1000. Estimating the value of the single outfits on the same basis, although they will cost somewhat more, the total investment represented is not far from $300,000, to say nothing of the property value of the stables, and the other equipment incidental to the use of horses. Considering the entire delivery service of the company, it is not unreasonable to assume that it has an actual valuation of $400,000. As this capital does not produce anything, and no revenue can be credited to the company, it will be understood that it is desirable to keep the delivery expense to the lowest figure possible.

The business of the company is very large and the tonnage handled, including both anthracite and bituminous coal, will probably considerably exceed 1,000,000 tons annually. The company does both wholesale and retail selling, and the statement made relates to what may be regarded as local deliveries only. The yards were located with reference to economizing and conveniencing delivery, for distribution from one central point would necessitate longer haulage and greater cost than from the different places in the city. But water front locations are essential because of the receipts by vessel and the larger the cargoes the more advantageous the transportation charges.

With the enormous distribution and the need of supplying the customers promptly the value of equipment that will be economical and dependable can be understood. Having used horses for transportation for years, the company decided to make experiment with motor vehicles, and after careful consideration of the possibilities of mechanical wagons a Couple-Gear four-wheel driven truck of five tons capacity was purchased, delivery being taken in March, 1911. No change was made in the machine, but it was equipped with a body with the customary form of hand-operated hoist, such as are generally used on horse carts.

The intention was to experiment extensively with this machine, with a view of determining the cost of operating it in varied service, and to make comparison with the expense of making delivery with horses. The truck is a standard Couple-Gear construction, which is ordinarily equipped with a single battery, and has a capacity of approximately 35 miles, half the distance loaded. As the intention was to work it in what might be regarded as long hauls a second battery was ordered, which practically doubled the mileage of the machine when the conditions were such the battery could be changed.

As might be assumed, the introduction of the truck necessitated the keeping of records that would, it was believed, afford accurate information, but because of the rather unfavorable conditions, the comparison of a machine operated by men practically inexperienced with work accomplished by a large and highly efficient organization, it was not found possible to determine facts that could be accepted without question. As a matter of fact, considerable time was required to gain such knowledge of the truck as would make possible a full realization of its productiveness.

The machine was stationed at the Southampton street yard, which is at the north end of the Dorchester district of the city, from which deliveries are made a considerable distance. A garage was extemporized and a charging panel installed to charge the batteries, and a man detailed to supervise the charging and to give the other attention necessary. In this connection it should be understood that the cost of caring for the truck was, and is now, comparatively high, for one

man can attend a dozen machines without difficulty during a night, and this would minimize the proportionate expense. The truck was utilized for long hauls generally, but occasional experiments were made in delivering single and divided loads, so a very good idea was obtained of the possibilities with it.

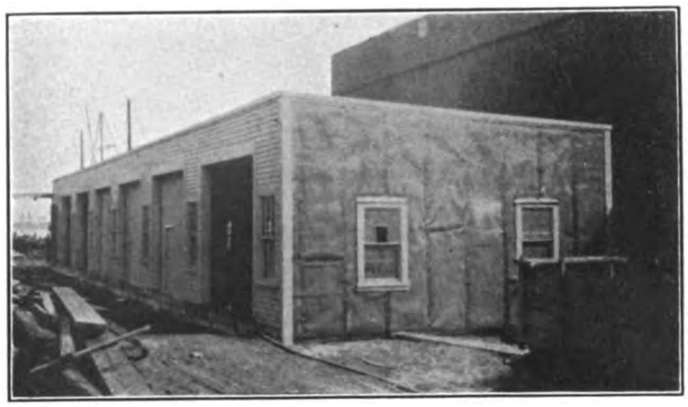
It was found that the truck could be worked to capacity the entire time it was in service each day, and that it had with a change of batteries a radius of movement that was equal to every requirement, and that during the severest winter weather the machine climbed every grade with full load and never failed, no matter how deep the snow or what the condition of streets. The results were such that the company decided to make further experiment, this time with the Eldridge front-wheel driven carts, these being so constructed that it was regarded as possible to utilize the horse carts. These machines are built with a forebody carrying the battery, driver's seat, controller, dash and footboards mounted on springs carried on an axle, which has two Couple-Gear wheels. To this is connected a body and rear wheels shod with steel tires. The battery capacity is rated as 25 to 30 miles, according to the character of the streets, and the maximum load is five tons.

From the viewpoint of the company, if this equipment was found practicable it would be possible to utilize the bodies, rear wheels and axles of a large number of the coal carts then in use, this being a very large saving when the value of the carts is considered, while the steel tires, if found practically serviceable, would mean a very large economy in operating expense when compared with the cost and the comparatively short life of rubber. These machines have not the mileage capacity of the four-wheel trucks without a change of batteries, but with spare battery equipment they may be worked so long as changes are made.

The first of these carts was received in January, 1912, and during the spring, summer and autumn five others were delivered, making a total of six now in service. In working these it was realized that it would be necessary to have facilities for storing and charging them, though until late in the summer the carts were kept at the Atlantic Avenue Electric Garage. At that time the company erected a garage building on its Summer street wharf, a wooden structure that is designed to allow further expansion, in which the machines are now housed, but the four-wheel driven truck is still stationed at and operated from the Southampton street yard.

The service given at the Atlantic Avenue Electric Garage was in every way satisfactory, for it is conducted by a committee representing the Electric Motor Car Club of Boston, and it was established to demonstrate the possibilities of such garages as private enterprises, but it was decided by the company that when it had six machines it was justified in establishing its own service station. The principal purpose to be accomplished was economy. The garage was equipped with a 50 horsepower 30 kilowatt motor generator, and a mechanic was engaged who has charge of the plant, charging the batteries at night, while during the noon hour the batteries are usually "boosted," this insuring the desired mileage.

The garage is a long, single-story structure that has a series of wide doors along the front side, and by opening these doors the machines may be backed into the bays or spaces for them, while they may be as readily driven out. The form of the building minimizes the work, eliminates the possibility of accident and obviates turning or moving a machine, either in the building or in the yard in front of it, and making it possible for any driver to take his machine into or from the garage without loss of time. There is sufficient room in the structure so that each cart may be worked upon without inconvenience, and there is abundant light. The charging installation will charge the six batteries at one time, and it is instantly available whenever current is needed. The equipment includes such tools as might be ordinarily needed in work on the carts, and it is possible to have special jobs done quickly in the event of emergency. A



The Garage for the Five-Ton Electric Eldridge Front-Wheel Driven Carts of the Metropolitan Coal Company, Summer Street Wharf, Boston, Mass.

stock of such parts as are required for replacements because of wear is carried, and a spare wheel and motor will permit repair of any wheel in comparatively short time.

The fore-wheel drive was adopted with a view of utilizing the bodies and rear wheels and axles of the horse carts, but while these have thus far been utilized, the experience of the company has not been favorable to such adaptation. This is due to the fact that the carts are driven at about twice the speed of horses, and the horse carts were not built heavy enough to withstand the extreme stresses of constant use on paving at the rate of five or six miles an hour. The construction of the carts is massive, but the components should be much heavier to endure the pounding they are subjected to with steel tires. While it is practical to use the horse carts for a time they cannot be sufficiently strengthened to be regarded as permanent equipment, and after they have been in service a short time it is necessary to repair them. Thereafter the maintenance expense is quite certain to be consider-

able. With bodies and wheels and axles specially built there is no reason to believe there will be any unusual cost of upkeep, but the use of horse equipment, while at first a saving, becomes an expense of considerable proportions eventually.

The company uses the carts principally for the haulage of bituminous coal, and very generally from the Summer street yard within a radius of two miles. The carts have a capacity of five tons and a mileage of 20 miles or better is made daily. The speed of the carts is approximately double that of horses, and it is practical to regard that each does the work of two two-horse carts, one man doing the work ordinarily done by two drivers. The work done by the machines is that for which horse carts would ordinarily be used, and there are no special hauls made in which they might be the most economical. In fact, it would appear that the machine would, in view of the experiences of others with them, be most productive in hauls of from two to four miles, but this character of work has not been chosen.

So far the electrics have given a very good measure of satisfaction, aside from the use of horse cart bodies, wheels and axles, and when it is realized that the efficiency increases with experience and the practical knowledge of the machines it may be understood that even more satisfactory results can be expected. The company may be said to be experimenting on what may appear to be a large scale, and while the immediate purchase of others is not contemplated, endeavor is being made to determine exact operating costs. Because of the fact that the company did not have its own garage until less than a year ago, and a considerable time must elapse before its organization is systematized and obtaining dependable figures, no definite figures are available. There are other factors, which have been stated, that must also be considered.

One of the problems given careful attention is the care and maintenance of the batteries. Because of the character of work for which the machines are used, and the presence of more or less dust, considerable difficulty is experienced in keeping the batteries clean, but it is expected that this can be largely overcome by better housing them and preventing foreign matter entering the boxes. Not only this, with the greater experience better results from them in longevity and capacity are naturally anticipated. The company has given considerable attention to tires. The cost of tires is a considerable item of expense, and while but two are used on a vehicle, the desire is to minimize this cost so far as possible. Originally the machines were equipped with block tires on the traction wheels, and later band shoes were used, but now block tires are being placed on the wheels whenever renewals are necessary. The belief is that block tires are giving the better mileage and traction, and for this reason the change is being made. The mileage from each type of tire is not less than can be reasonably expected, but the block form appears to afford the larger.

Of course, the greater experience has been with the four-wheel driven machine, and there is no doubt of the work that can be done with this, and yet the conditions under which it is used will not yield figures as favorable as were a number in service. At the Southampton street station a Mack five-ton truck has been used about a year, also on an experimental basis, and this has been used for practically the same work as the four-wheel driven truck. Of course the radius of movement of this machine is comparatively large, but this is of no special advantage because the company does not care for business that requires extremely long hauls, as the cost of delivery is prohibitive. This machine has a very large reserve, but as a rule this is not utilized. Normally neither machine is used longer than the regular working hours.

As to figures that will make possible the actual comparison of operating costs, the head of the transportation department says frankly that it takes a long time to ascertain the data that will allow exact determination, and there are variables that can only be learned by careful observation and averaged, a process that requires time. As a whole, the company is very favorably impressed with the results that have been thus far obtained. It purposes to economize its delivery and when sufficient facts have been obtained so that a decision can be made with certainty, there is no question that it will adopt the equipment that is known will best serve. With the capital invested in delivery equipment a transition is a problem of large moment, and there is no intention of making a mistake.

VETERINARIES AND BLACKSMITHS.

KisselKar Man Estimates This Income in America at $60,262,000 a Year.

Frank J. Edwards of the Kissel Motor Car Company, Hartford, Wis., maker of KisselKar trucks, has given some interesting facts relative to the transportation problems which are rarely considered by prospective purchasers of motor trucks. According to the census takers of the United States, there are 6567 veterinary surgeons and 23,554 owners of blacksmith shops, and Mr. Edwards maintains that it is conservative to assume that these 30,131 people average a gross income of $2000 a year, or in the aggregate, $60,262,000, derived principally from treating ill and disabled horses, shoeing them and repairing wagons.

"So it will be seen," says Mr. Edwards, "that there is quite something to consider in horse maintenance besides the consumption of food. We seldom have much trouble in proving the superior reliability and efficiency of the motor truck over horses, and in a large majority of cases the economy argument would be just as convincing if business men would keep more accurate records of horse hauling costs. Feeding, stabling, grooming, drivers' wages—those are about all the items of horse maintenance and operation that are generally submitted by the prospective truck buyer who wants comparative figures."

HAULAGE OF BUILDING MATERIALS.

Motor Trucks Economical in Delivery of Crushed Stone by Large Companies in Boston's Suburbs, as Shown by Comparative Work with Animal Equipment.

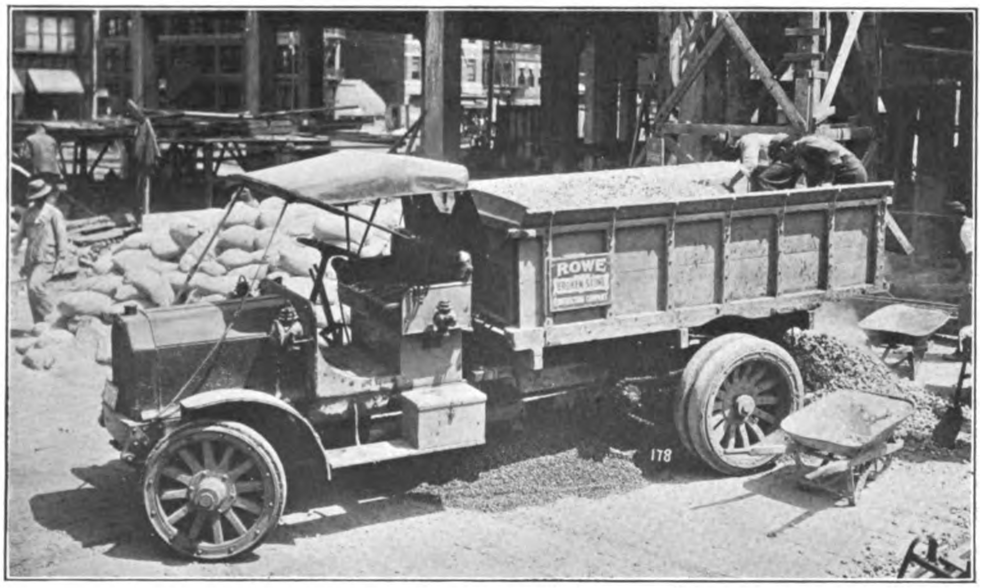
THE use of concrete for construction has become very general, one of the factors being the comparatively low cost, and another of equal importance is the fact that a structure of concrete may be made well nigh fireproof. This material is practical for every form of work and, when reinforced with metal, has remarkable strength. One of the three ingredients is crushed stone, which is superior to gravel from the fact that the rough surfaces insure unity with the cement, and a considerably larger proportion of stone can be used than when gravel is utilized.

There are certain qualities of stone that are desirable for crushing. While in cement a comparatively soft rock will perhaps serve satisfactorily, those who deal in crushed stone usually select a trap that will endure pulverizing influences, for this can be used for highway construction with excellent results, and it is equally serviceable for all other purposes.

In large cities where much construction is in progress the greater part of the year, and where street and road improvement is demanded, crushed stone is becoming more and more a necessity. In fact, it is quite as necessary as any other building material, and it is used in larger quantities each year. This demand has impelled the establishment of quarries and stone crushing plants as commercial necessities, and some of these are operated on a large scale. Stone may appear plentiful, but the desired quality is not always available, and when a satisfactory rock is found it is evident that the profit is proportionate to the production. That is, the larger the tonnage turned out the less the cost a ton. Some plants are so located that the stone may be shipped by railroad, but the majority of them are where the stone must be hauled by road vehicle.

While the demand may be large, it is apparent that transportation costs money, and each additional mile the cost increases, so that within a comparatively short distance the price will be so much increased that it will be prohibitive or will at least stimulate competition. That is to say, that were there a uniform price for crushed stone delivered at the crusher, and the expense of haulage added, the cost would be doubled with a haul of more than 7.5 miles, and, under some circumstances, in a lesser distance. In other words, the value of the stone is so small that it is unprofitable to haul it under the most favorable conditions, on good highways and without delays, for the prices that can be obtained.

It will be understood that where large quantities of stone are used, especially for highway purposes, municipal stone crushers are generally established, and in state work crushers are moved from time to time to meet the requirements of the work, the stone being hauled to them. These plants, however, do not always afford the quality of stone that is desired. It is not practical to make comparison of the cost of stone crushed under such circumstances, for the haulage must be added to the expense of production, a charge that is minimized or covered by handling with the quarry crusher.



Five-Ton Peerless Truck, One of a Fleet of Six Machines Used by the Rowe Construction Company at Its Crushers at Brighton.

Viewed by the highway contractor or builder the portable or movable crusher has advantages, but often the quality of the stone is inferior. If stone can be procured near it the price may be comparatively low, but to pay for haulage for material and for delivery rapidly increases the expense. The highway builder may have a roadside crusher and buy stone hauled by those who find the sale of rock an incentive to clear land, but it is hardly probable that it would be economy to establish a plant for crushing stone for structural purposes. In any event there would be the initial investment, and the haulage of stone would be so costly that it would be impossible to successfully compete with those who make the crushing of stone a business.

These statements have been made because the factors dealt with have important bearing on the sale of crushed stone. Summarized, it may be said that con-

Five-Ton White Truck, One of a Fleet of Three Machines Used by the New England Crushed Stone Company at Its Dorchester Quarry.

stone is delivered to the city of Boston for street construction, some is taken by contractors, and some is purchased for landscape work. The orders may vary from a few to many thousand tons and the hauls may be from a few hundred yards to six miles, and occasionally that distance may be exceeded to convenience a customer. This concern has a delivery equipment which includes 80 horses, about 40 carts and wagons, and six motor trucks, of which three are Packard three-ton machines, two are five-ton Alcos and one four-ton Peerless. The trucks and carts are equipped with quick discharging bodies, and at the plants all are loaded by gravity by chutes from the stone pockets. Thus it will be seen that, as practically all deliveries are made by dumping, there is no advantage obtaining in the trucks save in the greater capacity and the increased speed.

ditions that cannot be controlled limit the productive market to a radius of 7.5 miles from a plant, and this area cannot be extended save in the shipment of large tonnage by railroad or by tractor and trailer trains. It is practical, where the orders are of considerable size, to use tractors and trailers, for such equipment would be productive for about half the mileage, and the ton-mile expense of haulage would be proportionately reduced, but when the deliveries are of small quantities the trailers would not be practicable. In states where the size of the vehicle and the load are limited by law, as in Massachusetts, whether or not a tractor and trailers would be prohibited is a question not yet determined, but there is no certainty they could be used. Theoretically the laws specify vehicles of given weights and carrying definite loads, and there could seemingly be no application to trains of wagons or carts drawn by a tractor, each unit of which would be within the prescribed limits, but what might be decided by a legal or judicial mind is quite uncertain.

The Rowe Construction Company, which operates two stone-crushing plants in the Brighton district of Boston, and another in the city of Malden, is one of the largest enterprises of the kind in New England that does not ship stone by railroad. All of the production of 600 to 700 tons a day is delivered to customers within a radius of approximately six miles of the crusher, and this means that with a working year of about nine months, and approximately 230 business days, about 150,000 tons of stone are distributed.

A considerable part of this

The company purchased its trucks about the same time, taking delivery about the first of June, 1911, and it has operated them since then, a period of 26 months. Strangely enough, the company has, since it bought the machines, nearly trebled its horses, this being due to the increase in its business. That no more trucks were purchased was from the fact that the company desires to get accurate information relative to horse and motor truck cost, and has sought to do this by comparisons of the service records. The data must necessarily cover a considerable period and the machines must be given a thorough trial under all conditions of operation.

In making definite statement of results the com-

Five-Ton Mack Truck, One of Fleet of Three Machines in the Service of the West Roxbury Trap Company.

pany roughly makes comparison that the three-ton trucks are equal to two two-horse carts, and the four and five-ton trucks are equal to or better than four two-horse carts. But this may be qualified by the fact that the company does not generally use the machines for a lesser distance than three miles, and so they are ordinarily used for delivery in the longest hauls. The trucks are worked from the Brighton quarries, as at Malden the roads about the plant are exceedingly rough and the strain and stresses are unusually severe when the machines are driven upon them. In fact, the company believes that it is not economical to use them here in view of the possibilities of damage.

The trucks are driven an average of about 55 miles daily, and while it is not possible to average the tonnage because of the variance in the hauls, it is said by the company that the Peerless machine does nearly as much work as the five-ton trucks, for it is faster, and this is a factor of much importance in long hauls. The cost of operation may be best judged from the estimate of the value of the trucks when compared with horses, and a two-horse cart and driver may be hired for $6 a day, this being the prevailing price. If animal carts are profitable at this cost, then a truck that will cost $12 a day that will do the work of two such outfits is equally remunerative. And judging from the same basis a truck that will cost comparatively less and yet do the work of four carts or more, is a still better proposition. But with horses the company has found its haulage cost of stone to be about 13 cents a ton-mile. That is, to deliver a load of four tons three miles will cost with its own equipment $1.55, which is seemingly very low. On the basis of 13 cents a mile and an average of 55 miles a day for each machine, half the distance loaded to capacity, the five-ton trucks would earn $17.87, the four-ton trucks $14.30 and the three-ton trucks $10.72. There is this advantage with the trucks, however, that during the period of the year they are not used the cost is confined to interest on the investment and insurance.

The company has a garage at one of its yards, where the machines are stored, and this is in charge of a mechanic, who is required to give the trucks whatever attention is necessary and maintain them in operative condition. The overhauls and large repairs beyond the facilities of the garage are made at the service stations of the company. This concern has found the machines productive in that they are a decided economy in the manner they are worked, but were they used for short as well as long hauls, there would be better information available as to their productiveness in comparison with horse work of all kinds.

The New England Crushed Stone Company has its plant close to Franklin Park, in Jamaica Plain, and this is a quarry of trap rock and a crusher that has a capacity of several hundred tons daily. This company has a ready sale for its production, and it is to be compared with the Rowe Construction Company, so far as limitations for delivery through the cost of haulage. This company has three five-ton trucks in regular use, two Whites and one Mack, and these deliver the greater part of the rock crushed, there being a comparatively small part hauled by those who purchase it at the quarry. The company bought its trucks last season and has used them during the entire period the crusher was operated, the work being both short and long hauls. Prior to the use of trucks the company had horse equipment. The company is not inclined to make statements relative to the work that is accomplished with machines other than to state that they

Five-Ton White Truck Loading at the Stone Crusher of the West Roxbury Trap Rock Company, Boston, Mass.

are driven generally 50 and sometimes as much as 60 miles a day, and that they have given satisfactory service.

The company has a garage at the quarry in which the machines are kept, and this is in charge of a mechanic, who is responsible for the operation of the trucks. He is required to maintain them in a serviceable condition, and has the usual hand tools and equipment for making ordinary replacements and adjustments. In the event of extensive work the machines are sent to the service stations of the manufacturers.

The West Roxbury Trap Rock Company, which has a quarry and stone crusher near Walnut street, West Roxbury, not far from the Dedham line, is operated by Thomas F. Welch, a contractor, and besides supplying his own needs he has developed a considerable business in that section of Boston from Forest Hills to Dedham. The rock is delivered within a radius of about six miles, and as there is a great deal

of development and construction work in progress in that part of Boston, besides street and highway building, the plant is worked to its capacity practically all of the time. The stone was delivered by horses until about a year ago, when a White five-ton truck was purchased, and later a Mack and a Garford truck of the same capacity were bought. These machines are worked constantly and there is no idle time for them during the business part of the year. One of them is driven by the son of the owner, and his knowledge of driving and mechanics has been very serviceable, as he oversees the work of the other men and sees to it that the trucks receive the care and attention they should have. The machines are kept in a small garage at the quarry, and they are cared for by the drivers unless a repair of considerable importance, or requiring special facilities, is necessary. The mileage will run from 50 to 60 miles daily and the trucks are regarded as being at least equal to three two-horse teams and carts for stone delivery. The lack of records prevents a more definite statement or a very accurate idea of operating cost. There is no doubt, however, of the productive mileage driven daily, and the fact that the machines are practically all the time in service.

GOOD TIME FOR BUICK WAGON.

Covers 715 Miles Between San Francisco and Portland, Ore., in Practically 61 Hours.

A Buick delivery wagon of 1500 pounds capacity, has established a record between San Francisco, Cal., and Portland, Ore., that closely rivals that made by pleasure cars. The machine, which was manned by Claude McGee and Fred Gross of the Howard Automobile Company, San Francisco, Buick distributor, was loaded with exactly 1500 pounds of hardware, in addition to the baggage of the two men, and started for the northern city.

The actual elapsed time for the trip was 61 hours and five minutes. The distance is 715 miles and the time made comes within three hours of the pleasure car mark. In the report of the pilots it is stated that the entire run was made without the least mechanical difficulty and that the Goodyear tires used hardly showed a scratch as a result of the hard grind over the northern roads. Heavy grades were encountered in the Cascade and Sierra ranges.

RECORD BOSTON-NEW YORK TRIP.

Two Kelly Trucks Transport Furniture Over the Road on an Economical Basis.

Two one-ton Kelly trucks, made by the Kelly-Springfield Motor Truck Company, Springfield, O., and owned by Hersum & Co., Boston, Mass., recently made a record run from Boston to New York City and return. They carried two capacity loads of high grade furniture on the first half of the long run and delivered it in New York in perfect condition. The distance between the two cities is 242 miles, and the Kelly machines covered it in 22 hours and 50 minutes. The return trip was made without a load and took just 19 hours. The average speed loaded was 10.6 miles an hour, and returning, 12.7 miles.

The best record made was the economy in the consumption of gasoline and lubricating oil, both trucks using 90 gallons of gasoline, the average being 10.8 miles a gallon. Ten quarts of lubricating oil were used for the remarkable average of 96.8 miles a quart. The entire trip was made without an adjustment of any kind, and the two Kellys went through from start to finish without a hitch.

TO COMPETE WITH RAILROADS.

Motor Truck Club of Los Angeles to Operate Freight Line Over Special Highway.

An illustration of how firmly the mechanical transport has become established in this country is given in the action taken recently by the Motor Truck Club of Los Angeles, Cal. The club has announced that it will compete with the railroads running from that city to the harbor of San Pedro, about 20 miles distant, by operating a fleet of motor trucks over a specially constructed road. The members are going to back their belief in the economy and efficiency of the truck to the extent of over $350,000, which the road will cost.

The highway will be especially adapted to the use of heavy trucks, and every kind of merchandise will be transported from San Pedro, where it is laid down by ocean steamers, to the wholesale and retail districts of Los Angeles. The work is now being done by steam and electric railways, but there has long been general dissatisfaction against the slow, expensive service merchants have been getting. With commercial vehicles it is estimated that better service can be given at a minimum cost.

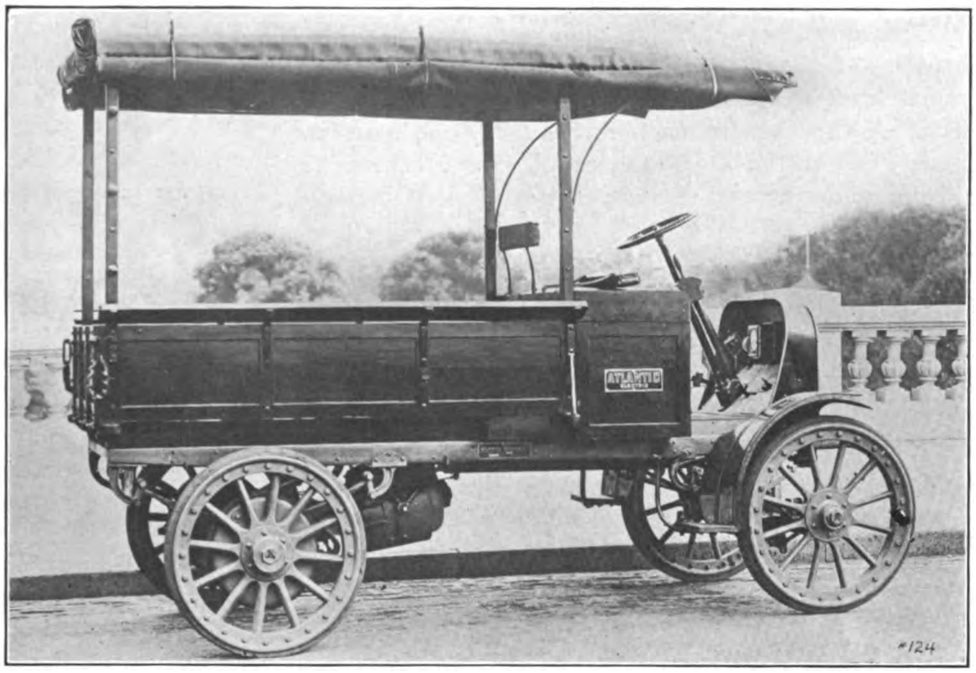
Detailed statistics of the carriage and wagon industry of the nation for the year of 1909, shortly to be issued by the census bureau of the Department of Commerce, show that there were in that year 5492 establishments that gave employment to an average of 82,944 persons, of whom 69,928 were wage earners, who were paid $45,555,126 in salaries and wages. The total cost of material used was $81,951,288 and the total value of the products was $159,892,547. The total capital invested was $175,473,728. The total number of vehicles manufactured was 1,519,782, as compared with 1,711,529 in 1904, this decrease being attributed to the manufacture of automobiles and motor trucks, and a considerable number of the concerns reported in censuses prior to 1909 as manufacturing wagons and carriages have since turned wholly or in part to the manufacture of automobiles and are now represented in the automobile classification. Ohio was the leading state in value of production.

NEW ATLANTIC 1000-POUND WAGON.

THE Atlantic Vehicle Company, with offices and salesrooms at 1600 Broadway, New York City, and factory at Newark, N. J., builder of the "long distance" Atlantic electric wagons and trucks, has begun the production of a 1000-pound wagon designed for general delivery purposes. The experimental and development work has extended over a considerable period, and the building of the machines commercially has been begun, the initial orders including an ambulance and a bank wagon for the Bethlehem Steel Company, Bethlehem, Penn., and an ambulance for the Didier-March Company, South Bethlehem, Penn.

The wagon is designed for the delivery of light loads at comparatively fast speed, the normal capacity permitting operation at 15 miles an hour, while it is maintained that it can be driven 65 miles on a single battery charge. It is unusual in that the motor is coupled directly to the rear axle housing, and the drive is through reduction gears to the full floating rear axle. The weight of the chassis is 2700 pounds. The chassis length is 140.5 inches and the wheelbase 102, and the machine can be turned in a radius of 25 feet, a very important factor in congested traffic or in narrow thoroughfares.

The chassis frame is heavily constructed of pressed steel, and it may be designed for either an underslung battery or a battery installed under the driver's seat. The accompanying illustration shows the last-mentioned type of chassis. Either type is produced at option of the purchaser.



The New Model Shaft-Driven 1000-Pound Atlantic Delivery Wagon, with Battery Under the Seat, Produced by the Atlantic Vehicle Company.

The motor is a standard production of the General Electric Company, 85 volts, 35 amperes, with maximum capacity at 800 revolutions a minute. The motor is enclosed in a water and dust tight steel frame, and as installed it is encircled with a heavy strap carrying trunnions at either side. These trunnions are mounted in stout brackets carried on two chassis frame cross members, so that the motor may be swung freely on them. Bolted to the motor frame at the pinion end is a cast steel housing, that encloses the short driving shaft, and two large pressed steel channels that serve as struts, the housing and the channels being in turn bolted to the rear axle housing. The rear axle is a full floating type, housed in a pressed steel shell, and this contains the differential gears and the driving shafts, the gear reduction being 5:1. Both the rear and the front axle are standard Timken productions, being of designs to have great endurance and fitted with Timken roller bearings for the wheel spindles and the steering pivots.

The chassis frame is mounted on semi-elliptic springs forward and rear, made from Krupp silico-manganese steel, the forward ends of the front springs being fixed in the spring horns, and the other ends being carried by large shackles. The spring hangers are steel castings, fitted with bronze bushings, and the springs are secured by self-lubricating bolts. This construction makes for long endurance and comparative ease of renewals of bushings when wear necessitates. The steering gear is a Ross construction of the irreversible type, with a hand wheel 16 inches diameter. The steering linkage is composed of steel forgings of ample size to insure satisfactory endurance. When the chassis is fitted with underslung battery the cradle is of substantial construction and the box is side loading, the doors closing tightly to afford the desired protection from dust and water. When the battery box forms the seat for the driver it is well covered and protected.

The wheels are of the regular artillery type, 12 spokes to a wheel, and are fitted with 34 or 36 by three-inch solid tires, these being the Goodrich demountable tires, made from a special compound that is intended to have high resiliency and long endurance. The brakes are both operated by pedals with direct linkage, one set internal expanding in and the other set external contracting on large steel drums attached to the rear wheels.

The controller is the General Electric Company's type S-103, form B, having four speeds forward and two reverse, the controller and the running and charging switch mounted as a single unit under the toe-

board. The controller is operated by a handle located conveniently under the steering wheel by a simple and positive linkage, and the lighting switch is also installed on the controller case on the steering column, where it can be easily reached. The running or main switch is a part of the control unit and it is operated by a removable key that projects through a slot in the toeboard, where it may be moved by the foot when desired. It is removable only in the neutral and charging positions. This may be used as an emergency switch in the event of need, such as the failure of the controller while the machine is moving. Then a kick will move the switch and cut off the current. The charging receptacle is dead at all times, save when the key is in a position for charging.

The dash is straight, with a short metal cowl for the protection of the indicating instruments and the lamps, and the regular equipment includes a Sangame ampere-hour motor, a Veeder hub cap odometer, two electric dash lamps, tail lamp, horn or bell, tail lamp and license bracket, charging plug and cable, and kit of tools. The body is optional with the purchaser, the normal loading space being 83 inches length and 40 inches width. As the machine has the same battery capacity as the 2000-pound wagon, its exceptional mileage under average operating conditions is understood.

FEDERAL AS STAGE COACH.

One Vehicle Replaces 32 Horses in Making Daily Trips Through Wyoming.

Many Federal motor trucks, made by the Federal Motor Truck Company, Detroit, are seeing service in the Far West, one of the latest being that sold to the Wamsutter-Slater Stage & Expressing Company in Wyoming. It is being used to cover a route hitherto travelled by stage coach and it passes through one of the most desolate sections of the country. To deliver the machine at Wamsutter it was driven from Denver, Col., and one stretch of 75 miles was encountered between Laramie and Medicine Bow, Wyoming, in which there was not a house, fence, post or telegraph pole.

The distance between Baggs and Wamsutter, the route over which the truck is used, is 50 miles. Formerly it required two changes of horses a day, or 24 horses for the round trip. The company also held eight horses in reserve for emergency use, so that the lone Federal has replaced 32 horses. The vehicle carries about 2700 pounds on its daily trip.

The Star-Tribune Motor Sales Company, Detroit, has placed in the market a delivery wagon with capacity of 1200 pounds. Small consumption of fuel is one of the qualities claimed for this machine, and it is maintained that an average of 24 miles to the gallon can be made on ordinary roads.

MARTIN TRACTOR COMPANY.

Organization with Capital of $300,000 to Manufacture Under Martin Patents.

The Martin Tractor Company has been organized at Springfield, Mass., with capital of $350,000, and it is purposed to begin the manufacture of tractors commercially under the patents issued to Charles H. Martin, to which it has exclusive right, save for the Knox Automobile Company, with the privilege of licensing the building of the machines by other manufacturers. Up to the present time the Martin tractors have been produced only by the Knox company. The demand for these machines has so greatly increased, and the prospect is so promising, that the company has been formed for production in such numbers as will meet the requirements of the market.

The officers of the company are: President, Harry G. Fisk; vice president and general manager, Charles H. Martin; treasurer, E. O. Sutton; secretary, C. E. Beckwith. One of the largest stockholders of the company is S. S. Eveland of Philadelphia, Penn.

NEW BOSCH BRANCH IN NEW YORK.

Field of Operations Will Include Eastern States and Afford Better Service.

The Bosch Magneto Company has relieved the executive officers and the staff of the New York office of the service work under their supervision by the organization of a separate department that will be known as the New York City branch, and which will operate in the eastern territory, which will include all the states east of the Ohio and the Mississippi rivers. The purpose is to give undivided attention to users of Bosch magnetos in that section of the country. The branch is located in the Bosch building, 223 West 46th street, New York, where it will remain until its growth or the demands of the other departments shall necessitate removal. The branch is in charge of Alfred J. Poole, formerly assistant chief engineer, who has an adequate corps of assistants.

A line of motor 'buses has been opened by W. W. Thompson to be operated over the old Albany post road between Tarrytown and Hastings, N. Y. The installation at present consists of two 40 horsepower Kelly-Springfield motor chassis, on which are mounted two 30-passenger, side entrance 'bus bodies. The machines leave Tarrytown hourly and arrive at Hastings 40 minutes later, passing through Irvington, Sleepy Hollow and Dobbs Ferry. Standard trolley car seats of two-passenger cross type with centre aisle are arranged, all facing forward. Electric push buttons are installed to signal when one desires to leave the vehicles, and clusters of electric lights in the centre of the roof light the vehicles at night.

CASE TRACTORS WIN IN WINNIPEG.

WHILE there were more classes in the sixth annual agricultural motor trials, held in conjunction with the Canadian Industrial Exhibition in Winnipeg, Manitoba, Canada, in July this year, than was true in 1912, and consequently a greater number of prize winners, an analysis of the official score sheets for the two years indicates somewhat less interest on the part of manufacturers. This year there were 10 classes, in which 19 machines of three different makes competed. Last year there were seven classes and 25 machines, representing 10 different makes. At the other hand there were two classes last year in which there was but one entrant each, while this year there was but one.

The Sawyer-Massey Steam Tractor and Trailer, Only Canadian Make to Compete in Trials.

The first prize winners were as follows: Division 1, class A, gasoline tractors with piston displacement of 300 cubic inches a minute or less, Case; class B, gasoline tractors with piston displacement of 300-500 cubic inches a minute, Case; class C, gasoline tractors with piston displacement of over 500 cubic inches a minute, Sawyer-Massey. Division 2, class A, kerosene tractors with piston displacement of 300 cubic inches a minute or less, Avery (no competition); class B, kerosene tractors with piston displacement of 300-500 cubic inches a minute, Case; class C, kerosene tractors with piston displacement of over 500 cubic inches a minute, Case. Division 3, class A, steam tractors with piston area in square feet times 200 times .8 equalling 60 or less, Case; class B, steam tractors with piston area, etc., equalling 60-100, Case; class C, steam tractors with piston area, etc., equalling over 100, Case.

A comparison of the general averages for the trials of 1911, 1912 and 1913 undoubtedly will prove of interest. It should be borne in mind that the price of gasoline has changed very materially during the past year, and in computing this year's results gasoline was figured at 27 cents a gallon of seven pounds, as compared with 19.5 cents in 1912. The price for 1911 was half a cent less than in 1912—hardly enough to affect the final result very materially, but worthy of being kept in mind during the consideration of these comparisons.

There was no class A for gasoline machines in 1912. This year, the score sheet shows an average fuel cost a brake horsepower of 2.81 cents in this class. Reducing this to the same price as in 1912, as a further basis of comparison, the result is 2.067. In class B, the average for 1911 was 1.648 cents, and for 1912, 1.787 cents. This year the average was 2.28 cents, or when reduced to 19.5 cents a gallon, 1.647. The average for class C in 1911 was 1.944 cents, and in 1912, 1.961. This year the average in this class was 2.87 on the face of the returns, or 2.072, when reduced to the same cost figures as last year. The average for all kerosene machines was: In 1911, 1.274 cents; 1912, 1.603; 1913, 1.625.

Of course, the averages based upon the cost of gasoline at 19.5 cents a gallon have no value this year in arriving at the relative economy of gasoline and kerosene machines. These figures only serve as a basis of comparison as to general efficiency and economy between this year's models and those of 1911 and 1912. The best score in this respect this year was made by the Case winner in the gasoline class B, this being 2.26 cents on the basis of 27 cents a gallon for

A Corner of the Exhibition Grounds at Winnipeg Industrial Exposition, Showing Some of the Machines Which Did Not Compete in the Trials.

A Gasoline Member of the Winning Case Team, Engaged in Plowing Test.

fuel, or 1.632 on the basis of 19.5 cents a gallon. The average for all gasoline machines in 1912 was 1.834, and the best score, 1.509, made by a Canadian Aultman & Taylor.

The relative economy of gasoline and kerosene machines was in favor of the latter both years. The best kerosene score in 1912 was 1.295 for a Rumely Oil-Pull, while the best showing this year was 1.41, made by a Case. The comparative figures for 1912 were, therefore, 1.509 for gasoline, as against 1.295 for kerosene (best scores), and for 1913, 2.26 for gasoline as against 1.41 for kerosene. The averages show 1.603 for kerosene machines in 1912 as against 1.834 for gasoline tractors, and for 1913, 1.625 for kerosene as against 2.71 for gasoline. It should be remembered that the price of kerosene was the same both years, 14.5 cents for a gallon of 7.9 pounds. In this consideration of the proposition gasoline is rated 27 cents a gallon this year, of course.

Coming now to the question of plowing, the figures given being the cost of fuel an acre plowed: In the gasoline class A, the average was 63.5 cents, or 45.8 cents when computed on the basis of 19.5 cents a gallon. There was no class A in 1912. In class B, the average for 1913 was 69.75 cents (50.37 at 19.5 cents a gallon), as against 54.03 for 1912. In class C the figures are 57.6 (41.6) in 1913, 49.15 in 1912 and 47.28 in 1911. These show a better relative economy between the models for the three years, when compared on the same basis of fuel cost. Insofar as class C is concerned, there appears to have been a decided improvement over 1911, there having been a loss of efficiency in this respect in 1912 over the previous year.

In the kerosene classes, the figures for 1913 show an average cost an acre plowed of 53.4 cents, 53.2 and 47.35, in classes A, B and C, respectively. There were no corresponding classes in 1911 or 1912. However, in 1912 the figures were: Class D, 52.6 cents, and class E, 45.1. The averages for all kerosene machines in the three years were: In 1911, 37.17 cents; 1912, 48.36; 1913, 50.9. The average for all gasoline machines in 1912 was 49.56 cents, and in 1913, 62.11.

The individual scores on the more important points, and the finals, are presented in the following table:

No.	Make.	H. P.	Cost B. H. P. Cents.	Cost Acre Cents.	Final Score.
	Division 1, Class A, Gasoline.				
1	Case	15	2.97	69.6	325.60
19	Avery	12	2.66	57.4	238.95
	Division 1, Class B, Gasoline.				
3	Case	20	2.26	57.6	352.00
2	Avery	20	2.30	81.9	316.75
	Division 1, Class C, Gasoline.				
4	Sawyer-Massey	25	2.66	56.6	359.05
5	Case	40	2.30	59.9	355.55
7	Avery	30	3.71	46.5	290.05
6	Case	40	2.81	67.4	154.05
	Division 2, Class A, Kerosene.				
8	Avery	12	1.90	53.4	193.10
	Division 2, Class B, Kerosene.

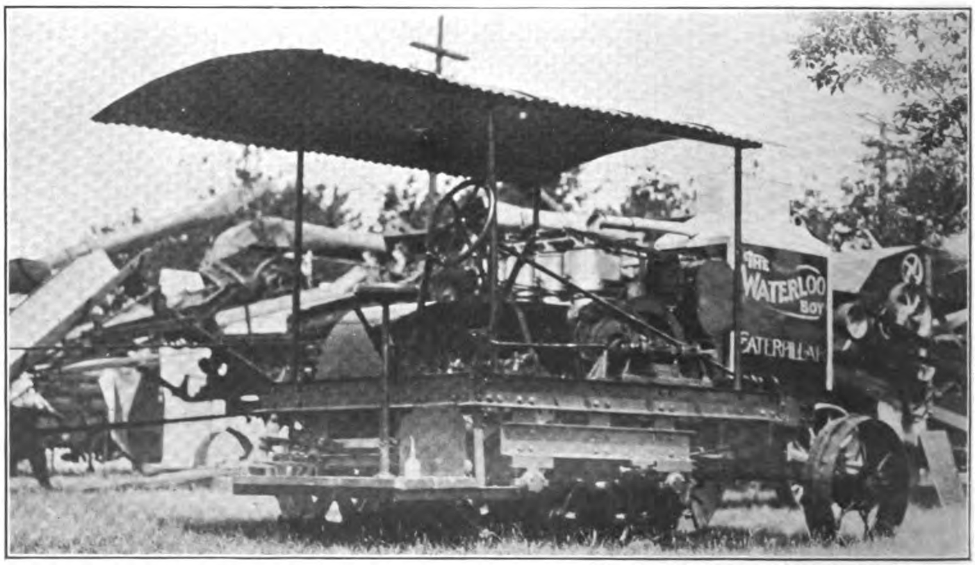
16	Sawyer-Massey	25	1.67	55.9	322.55
	Division 3, Class C, Steam.				
17	Case	..	1.06	37.0	437.30
18	Sawyer-Massey	35	1.67	49.5	349.80



Another View of the Exhibition Grounds, with the Caterpillar Tractor in the Foreground.

BRIEF NEWS OF MANUFACTURER AND THE TRADE

The A. O. Smith Company, Milwaukee, Wis., maker of Smith-Milwaukee trucks, announces that because of the necessity for additional space for its frames and other pressed steel parts, the manufacture of the Smith multiple disc clutch will be transferred to the Universal Machinery Company, Milwaukee, which will hereafter make the clutch under the supervision of the Smith company.

The E. V. Stratton Company, Albany, N. Y., which has done a splendid business in Hudson cars and Stewart trucks, has had its territory extended to include all of New York State west to and including Montgomery and Franklin counties, and south to part of Ulster and Duchess; five counties in Vermont and three in Massachusetts, including the city of Springfield. John S. Harrington, formerly of Worcester and Boston, has been secured by the Stratton company to handle Hudson cars and Stewart trucks in the Springfield district.

The Alma Motor Truck Company, maker of Alma trucks, has established its general sales office at 870 Woodward avenue, Detroit, with W. M. Hogle, general sales manager, in charge. The factories, as in the past, are located at Alma, Mich.

The Brodesser Manufacturing Company, Milwaukee, Wis., which has been making a delivery truck for the past two years, has been incorporated for $20,000 by P. H. Brodesser, Roman Brodessor and Harry Soulen. The new capital is to be used to enlarge the business.

The Brown Commercial Car Company, Peru, Ind., was the only exclusive truck manufacturer represented in the recent Indiana-Pacific tour of the Indiana Automobile Manufacturers' Association. The excellent performance of this internal gear-driven machine, carrying a supply of tires for the pleasure vehicles in the party, was such as to excite favorable comment throughout the journey. When it is remembered that the route selected included some of the worst roads in the country, as well as several mountain passes with exceptionally high altitudes, it readily will be seen that the test to which the truck was subjected was entirely out of the ordinary. The accompanying illustration shows the crew on the road near Jonesburg, Mo.

F. C. Brown, formerly branch manager at Albany, N. Y., for the Diamond Rubber Company, Akron, O., maker of Diamond tires, has been appointed New England district manager for the Chase Motor Truck Company, Syracuse, N. Y., maker of Chase air-cooled trucks, with headquarters in Boston.

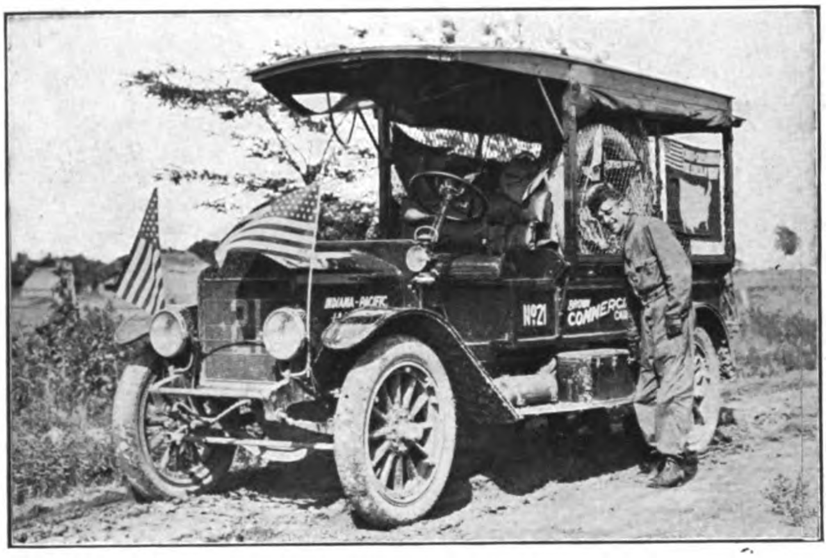
The property of the General Fire Extinguisher Company, in West Exchange, Bradford and Cedar streets, Providence, R. I., vacated by that company for a larger plant at South Auburn, R. I., is suited for manufacturing purposes, or it may be made a mammoth garage for motor trucks for comparatively trifling expense. The buildings are five in number, four of them directly connected, and the fifth connected by overhead passages, having a floor area of approximately 78,000 square feet. Buildings Nos. 1 and 3 are of brick, with three stories and high basements, and the other three structures are of brick and frame, or brick and stone construction. The buildings are piped for steam heat and for the Grinnell sprinkler system, the latter insuring minimum insurance rates. The location is convenient to the business section of Providence and is ideal for a garage and service station. The property, which has a total area of 84,644.46 square feet, can be purchased as a unit, or it may be divided into nine parts for the purpose of sale, the five buildings and four parts of unoccupied land. Full information may be obtained from G. L. & H. J. Gross, managers of estates, 170 Westminster street, Providence, R. I.

President Thomas L. Robinson of the Republic Rubber Company, Youngstown, O., maker of Republic tires, recently had as his guests at the Youngstown Country Club, branch managers, officials and department heads to the number of about 40. Dinner was served, after which speeches of a business nature were given. The list of guests included H. K. Wick, John C. Wick, Youngstown; M. E. Murray, San Francisco; C. W. Hardin, New York City; J. W. Maguire, Chicago; B. C. Swinehart, Philadelphia; B. F. Morris, Buffalo; W. S. Carleton, Boston; J. C. Kearns, Detroit; W. R. Goudie, F. G. Hill, H. W. Pratt, New York City; G. A. Sohl, Atlanta; J. Palmer, Chicago; F. W. Osmun, Minneapolis; G. M. Hoffman, St. Louis; G. N. Talcott, Cleveland; T. L. Robinson, president, Republic Rubber Company; L. T. Peterson, first vice president; J. H. Kelly, second vice president and general sales manager; A. H. Harris, superintendent; W. D. Morris, assistant general superintendent; C. F. Garrison, secretary; M. I. Arms, 2nd, treasurer; H. W. Bixler, assistant sales manager; Web Brown, advertising manager; N. W. Sayles, purchasing agent; G. L. Stansbury, auditor; O. M. Norby, manager, credit department; E. B. Frase, manager, hose department; Thomas Matchett, manager, belting department; T. J. Mell, inventor, Staggard tread; W. D. Norris, shipping clerk; C. A. Rice, M. E., E. E.; W. Dunn, paymaster.

H. S. Firestone, president of the Firestone Tire & Rubber Company, Akron, O., maker of Firestone tires, is touring abroad with his family. The party is motoring through France, Italy, Germany and Switzerland, and expects to return to Akron about Sept. 1.

Norman H. Halliday has been appointed by the International Motor Company, New York City, maker of Mack, Saurer and Hewitt trucks, as manager of its New England branch at Boston. Mr. Halliday is well known to the New England trade through his former connections with the Packard and Thomas companies.

H. C. Whitney, for several years general southern representative of the American Locomotive Company, New York City, maker of Alco trucks, and more recently connected with the Atlanta branch of the Locomobile Company of America, Bridgeport, Conn., maker of Locomobile trucks and pleasure cars, has taken the position of southern district manager of the Lozier Motor Company, Detroit, maker of Lozier cars.



The Brown 3000-Pound Internal Gear-Driven Wagon That Carried the Tires for the Competitors in the Indiana-Pacific Tour.

W. D. Clisbe of Detroit and J. W. Lucas of Benton Harbor, Mich., have secured the patents, patent drawings and trucks of a motor truck concern organized some time ago at Benton Harbor. It is planned to eventually employ between 2000 and 4000 men.

The Church Motor Car Company, Chicago, has been incorporated for $1,000,000 by A. G. Lattner, W. J. Maloney and N. P. Coffin. The company will build pleasure cars and trucks employing the Church automatic motor. Efforts are being made to secure a factory in Detroit and the permanent plant will be located in that city.

The Peerless Motor Car Company of New York, factory branch of the Peerless Motor Car Company, Cleveland, O., maker of Peerless trucks and pleasure cars, has appointed Fred H. Cozzens manager of the motor truck department.

The White Company, Cleveland, O., maker of White pleasure and commercial vehicles, recently opened a new salesroom and service station at 216-218 North Broad street, Philadelphia. As is true of all the branch houses of the White company, provision is made to take care of every need of White users in the entire district served by Philadelphia.

The Lauth-Juergens Motor Car Company, Fremont, O., maker of Lauth-Juergens trucks, has elected the following directors: J. Lauth and P. Lauth of Chicago; L. C. Worst, J. W. Worst, J. W. Forsyth, W. A. Lucas, L. W. Overmeyer and A. E. Culbert.

Thomas J. Holland, designer and patentee of a new style of flexible wheel for motor cars and trucks, has organized a company at Antigo, Wis., to manufacture and market the wheel. The corporate name of the concern is Holland Flexible Auto Wheel Company, and the capital stock is $10,000. Associated with Mr. Holland are James L. Donahue and John E. McKenna.

Henry O. Stenzel, president of the Milwaukee Tire & Supply Company, 457-459 Milwaukee street, Milwaukee, Wis., has organized the White Automobile Company to take the district agency for White cars and trucks, made by the White Company, Cleveland, O. Temporary quarters are in the Tire & Supply building on Milwaukee street and a garage and salesroom will be leased or erected this year.

W. J. Carter, late of the Oldsmobile St. Louis branch, is vice president of the Velie Motor Company of Missouri, St. Louis, Mo., incorporated recently to handle the Velie motor cars and trucks. Other officers are: President, J. A. Level; treasurer, J. R. Level; secretary, C. F. Swartz. Plans are being drawn for a three-story fireproof concrete salesroom and garage at Lake and Delmar avenues.

The Kissel Motor Car Company, Hartford, Wis., announces the following agents for KisselKar trucks and pleasure vehicles: J. T. Gentry, San Bernardino, Cal.; Blenn A. Calkins, Riverside, Cal.; Fred Duville, Pomona, Cal.; George Gilmore, El Centro, Cal.; Joseph S. Peoples, Petaluma, Cal.; Benjamin L. Brundage, Bakersfield, Cal.; P. J. Weisel & Co., Anaheim, Cal.; J. C. Phelan, Fresno, Cal.; Pacific KisselKar branch, Oakland, Cal.; West End garage, Santa Ana, Cal.; E. B. Jones, Hornell, N. Y.; Empire garage, Middletown, N. Y.; Flato & Allen, Kingsville, Tex.; Oliver-Nussbaum-Scharf Company, Grosbeck, Tex.; W. S. Mattox, Greenville, Tex.; Lyscio & Walker, Joplin, Mo.; Nemic & Biscenius, St. Cloud, Minn.; J. W. Bush, Oakes, N. D.; New Island City garage, Galveston, Tex.; Reno Nevada Company, Reno, Nev.; William Daly, Paterson, N. J.; Thomas Plimley, Victoria, B. C.; Kentucky KisselKar Sales Company, Lexington, Ky.; Waterloo KisselKar Company, Waterloo, Ia.; Douglass Motor Car Company, Douglass, Ariz.

The New Factory of the Electric Auto-Light Company at Toledo, O., Which Has Greatly Increased the Production of That Concern.

The Lewis Electric Welding & Manufacturing Company, West Toledo, O., is to build a new gray iron foundry to supply castings used in the construction of motor parts made by the concern.

The Transit Motor Truck Company is the new name of the Transit Motor Car Company, Louisville, Ky., maker of Transit trucks.

The Dayton Chainless Trucks, formerly made at Dayton, O., by A. E. Ausman, are to be built at Chattanooga, Tenn., according to a report recently issued. The vehicles will be known under the name Chattanooga.

The Huselton Motor Company, Butler, Penn., is a new truck concern which has begun the manufacture of vehicles of 1500 pounds capacity.

H. C. Mayo, one of the most popular salesmen in Boston, and for many years associated with the Peerless branch of that city, has joined the sales organization of the J. W. Maguire Company, agent for Pierce-Arrow pleasure vehicles and trucks. Mr. Mayo will travel through New Hampshire and Vermont.

Herbert P. Choate has become sales manager of the Star Motor Car Company, Ann Arbor, Mich., maker of Star trucks. He was formerly connected with the Empire Tire Company, Trenton, N. J. He has made arrangements with George C. Hupp and J. E. Hannon, the latter formerly secretary of the Michigan state fair, to act as Michigan distributor for the Star trucks. They have formed the Star-Tribune Motor Sales Company with headquarters at 815 Woodward avenue, Detroit, where Mr. Choate will be located. Mr. Hupp announces that he is still connected with the R-C-H Corporation, having resigned as an officer to become connected with the manufacture of the Tribune car, a new machine on the market.

Chanslor & Lyon, Los Angeles, Cal., distributor of Stromberg carburetors, made by the Stromberg Motor Devices Company, Chicago, has recently established a series of service stations throughout the Pacific Coast district for the accommodation of Stromberg users.

Harvey M. Briggs has succeeded Otto R. Bieler as chief engineer of the Lord Baltimore Motor Car Company, Baltimore, Md., maker of Lord Baltimore trucks.

H. S. Dunlevy has succeded L. C. Long as sales manager of the Chicago branch of the Federal Motor Truck Company, Detroit, maker of Federal trucks.

The Wood-Van de Verg Auto Company, 432-434 West Pico street, Los Angeles, Cal., has taken the agency for Krebs trucks, made by the Krebs Commercial Car Company, Clyde, O.

The Reliance Automobile Company, San Francisco, Cal., has taken the agency for Dart commercial vehicles, made by the Dart Manufacturing Company, Waterloo, Ia.

The Whitney Bros. Company, Santa Cruz, Cal., has taken the agency for Velie and Alco trucks.

The Stewart Motor Corporation, Buffalo, N. Y., has appointed the following distributors of Stewart delivery wagons: Charles L. Papworth, Lockport, N. Y.; Seacoast Garage Company, Asbury Park, N. J.; Edgewood Garage, Providence, R. I.; Van's Garage, Kingston, N. Y.; William Petry Garage, Hudson, N. Y.; Payne Automobile Company, Troy, N. Y.

The Electric Auto-Light Company, Toledo, O., maker of starting, lighting and ignition systems, has by the erection of the building shown by the accompanying illustration, increased the floor space of its plant more than 25,000 square feet. More than 100 additional workmen have been employed. The building has been equipped with high-grade automatic machinery. The company now has a capacity of 100 complete systems a day, but it is believed that it will be necessary to still further increase the production departments before the end of the year.

Fred A. Law, until recently superintendent of the Selden Motor Vehicle Company, Rochester, N. Y., maker of Selden trucks, has returned to Boston, where he is conducting a general supply agency. He was formerly identified with the Electric Vehicle Company, later the Columbia Motor Car Company, Hartford, Conn., having designed the first four-cylinder gasoline motor ever made by it.

E. George Walker, formerly connected with the sales forces of the Oldsmobile and Garford companies, has joined the Hartford Auto Parts Company, Hartford, Conn., as sales manager and service engineer.

Salt Lake Automobile Company, Salt Lake City, Utah, has established a truck service department in charge of a truck expert.

R. W. Kerns, formerly general superintendent of the Brecht-Butcher Supply Company, St. Louis, Mo., has joined the sales force of the Missouri Motor Car Company, and is now in charge of the truck department.

R. E. Frye, who has been identified with the Williams-Frye Sash & Door Company, St. Louis, Mo., where he is well known in business circles, is now general manager and an officer in the Lindsey Motor Car Company of that city.

The Holtzer-Cabot Electric Company, Brookline, Mass., is issuing a new booklet on Reacto horns, which the company manufactures.

The Adams Bros. Company, Findlay, O., manufacturer of Adams trucks, at its recent annual meeting elected the following officers for the coming year: President, Joseph W. Kwis; vice president, C. H. Bigelow; secretary, L. J. Adams; treasurer, B. B. Bigelow; general manager, W. D. McCaughey; purchasing agent, D. B. Adams.

W. S. Bashaw, owner of the Detroit Electric Car Company, has opened business at 108 Brady street, Davenport, Ia., and will handle the Detroit electric line, made by the Anderson Electric Car Company, Detroit.

The Auto Drive & Parts Company, Indianapolis, Ind., has been incorporated with a capital of $100,000. It will establish a factory at Indianapolis to manufacture drives and differentials invented by W. H. Harris.

The MOTOR TRUCK
Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., SEPTEMBER, 1913 No. 9

NATIONAL TESTS OF FIRE APPARATUS.

Gasoline Pumping Engine Trials, Under Exacting Conditions of Underwriters, Demonstrate Endurance and Capacity in Connection with International Convention of Chiefs' Association and Exhibition of Improved Equipment.

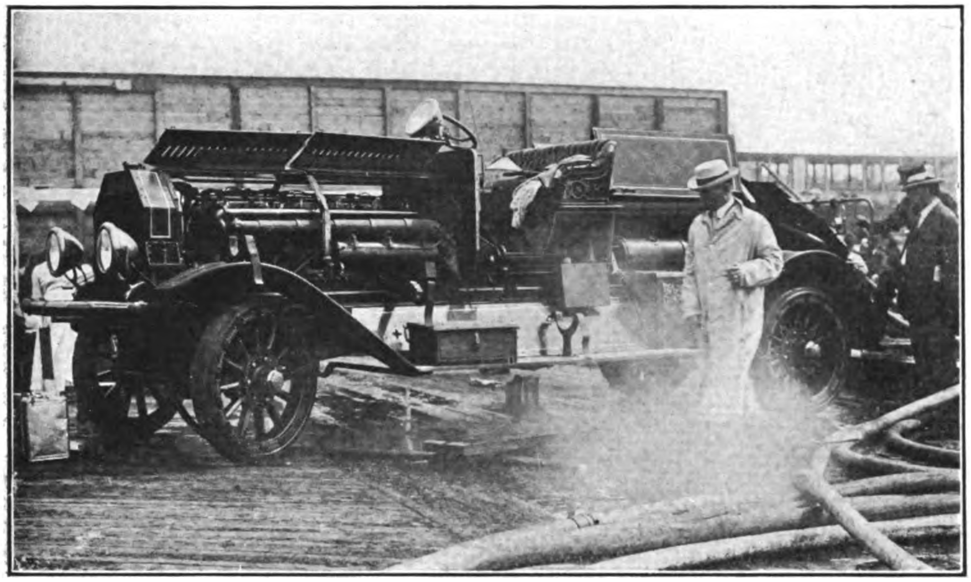
THE 41st annual convention of the International Association of Fire Engineers, held in New York City, Sept. 1-6, inclusive, was given over very largely to the consideration of motor propelled and motor pumping department equipment and maintenance, and in connection with the convention was an exhibition of motor apparatus by the makers, and a series of apparatus tests conducted under the direction of the National Board of Fire Underwriters. There were many other features in which the fire engineers were greatly interested, but these were foreign to the papers, the exhibition and the trials, and will not be considered in this article. Included in the exhibition were numerous displays of equipment for fire departments, accessories for departmental apparatus, differing forms of fire protection, protective and life-saving devices, and parts that are designed purposely for fire apparatus construction.

Observers Taking the Reading of the Nozzle Pressure, a Record That Was Made Every Five Minutes, and from Which the Actual Work Was Computed.

The convention was attended by more than 1200 chief engineers of fire departments from all parts of the United States, from Europe and from Egypt, and many thousands of firemen, municipal and fire department committees, and while those who attended the convention proceedings were comparatively few in number, it is true that the exhibition was visited by a very large number, while the trials were witnessed by practically all the chief engineers and committees. In connection with the exhibit numerous street and pumping demonstrations were made by the representatives of apparatus builders.

The convention has taken place three times in New York in the history of the association and during the meeting the visitors were entertained in a manner that was typical of New York, only more so than ever before. The weather was favorable, but the temperature was exceedingly high for four days, and then the visitors were privileged to witness one of the most severe electrical storms ever known in New York. The last two days of the sojourn in New York the temperature was lower and rain fell intermittently.

Father Knickerbocker has never been known to stint at entertainment, and the fire fighters were royally welcomed and their stay made memorable in many ways, for besides the convention, the exhibition and the trials, there were dinners, banquets, visitations to Coney Island and its attractions, while there were innumerable pleasures that were incidental to the formalities. In many of the places of amusement the engineers were given entre during their stay. Open house was kept by the New York firemen. Mayor



Chief John Kenlon Observing the 1000-Gallon Seagrave Pump Amid a Shower of Spray from a Leaky Coupling—This Machine Worked the Full 12 Hours of the Trial.

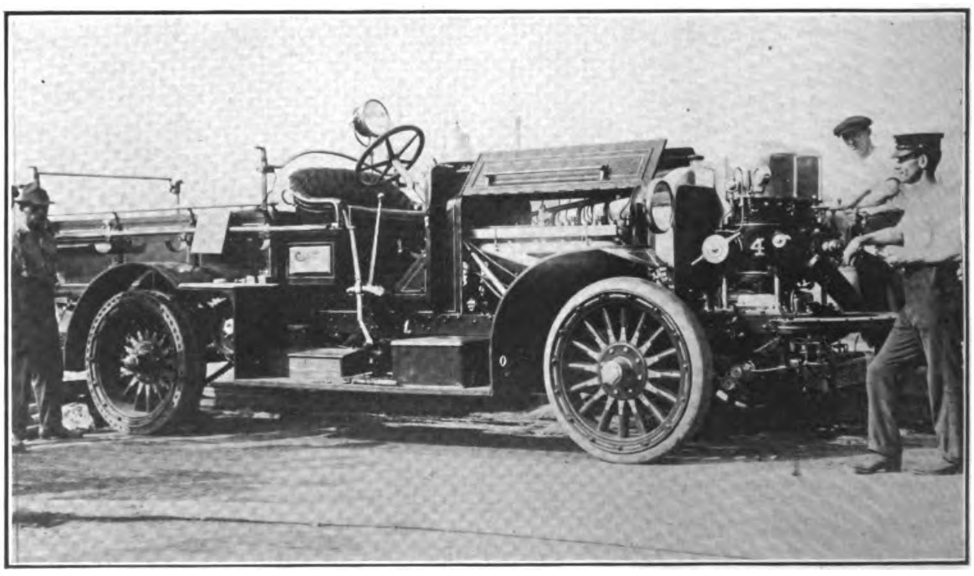
William J. Gaynor, Fire Commissioner Johnson, Chief John Kenlon and their subordinates, to say nothing of the 4500 men of the department, constituted an entertainment committee, and the municipal protective organization contributed an exhibition by the fire boats at the Battery, a boxing match by two skilled amateurs (both active firemen), and there was a battle to a finish between ball teams representing the police and fire departments. One of the features of the week was the unveiling of the Firemen's Memorial Monument at Riverside Drive and 100th street, in connection with which was a parade in which the New York department, all the visiting firemen, and numerous fire companies from New York and New Jersey were participants. The volunteer fire companies with their "parade" apparatus, were a distinct attraction, and in the line was seen everything from the antiquated hand pump to the latest constructions and many of the machines on exhibition. The finale was a banquet at the Hotel Astor the evening of Saturday, Sept. 6.

Such in brief outlines the events that continued through the six days and which will no doubt be memorable in the minds of all who were concerned in or had their attention directed toward the activities and pleasures of the occasion. Every minute of the time was taken up with convention duties, sightseeing and amusement, and the firemen certainly had strenuous lives for several days. But one day was devoted to honoring the dead of the New York fire department, there being a magnificent memorial dedicated by representative citizens with the assistance of the visitors and innumerable thousands of New Yorkers.

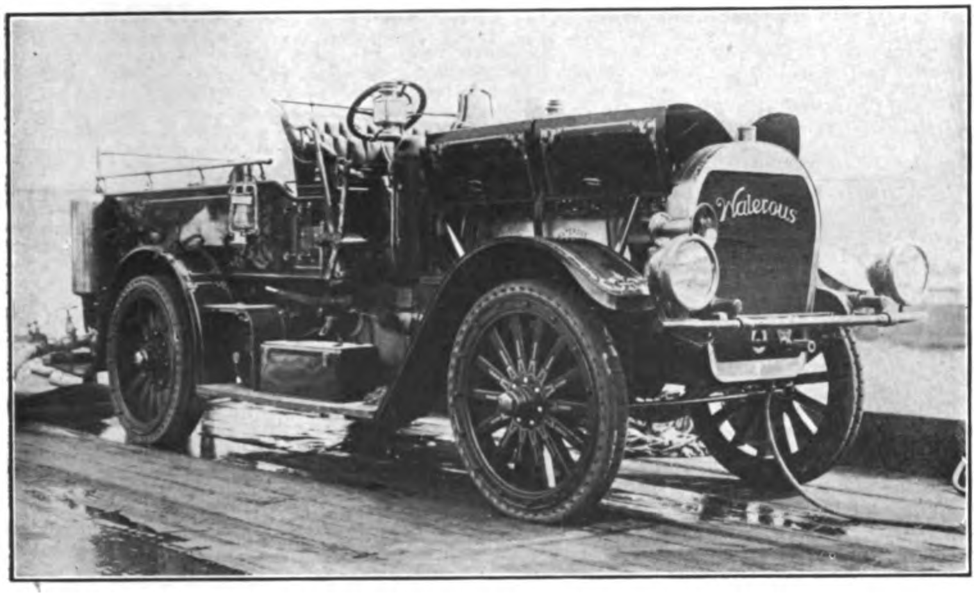
The convention itself was a notable gathering, there being in attendance men from all parts of the United States and Canada, while Chief M. J. Meier of the Amsterdam, Holland, fire department; Arthur Reginald Dyer, divisional officer of the London, England, fire brigade, and Major E. C. Walker, superintendent of the Alexandria, Egypt, fire brigade, were three of the notable engineers at the sessions. Chief Meier is president of the International Fire Service Council and is very well known and prominent in Europe.

So far as the sessions of the convention were concerned they were especially interesting to those having interest in motor propelled and motor operated apparatus. In all seven subjects were considered, and of these three dealt wholly with motorized equipment and its use. Two of these were papers read at the first session of the convention, and one was presented by Arthur R. Dyer, who described the London fire brigade's apparatus and the development of it from the hand or horse types to the motor vans, pumps and ladders. The third was an analysis of maintenance requirements for motor apparatus and was prepared with a very thorough knowledge of conditions by the head of the repair division of the New York fire department.

If there is any criticism of the convention it should be in the fact that the fire chiefs did not discuss the papers to the length that would appear desirable, for the discussions were written after careful study and observation and the conclusions were reached after mature deliberation and reflection.



Ahrens-Fox 700-Gallon Six-Cylinder Pump That Went Through the Three Successive Pumping Periods with a Perfect Score, Exceeding at All Times Its Rating.



Waterous Six-Cylinder 700-Gallon Pump That Worked Continuously 12 Hours with a Pumpage That Was Very Close to Its Rated Capacity.

There was one thing evident—that there was no interest whatever in horse apparatus. The heads of the city organizations had probably expressed themselves so definitely that there was not in the exhibition a horse equipment, unless it were a converted ladder truck that was originally intended to be drawn by hand and had been modernized by the substitution of a tractor for the original tongue. This could be used with horses, but these only when the runs were long.

The convention delegates without exception thought and talked motor apparatus. All of the spare time of the engineers was given over to the examination of the equipment displayed, but because of street demonstrations and the trials, official and to committees, some of the machines were absent from the Grand Central Palace a considerable part of the time. So far as the public was concerned there was incidental interest, and there was abundant opportunity for those who cared to do so to examine the exhibits.

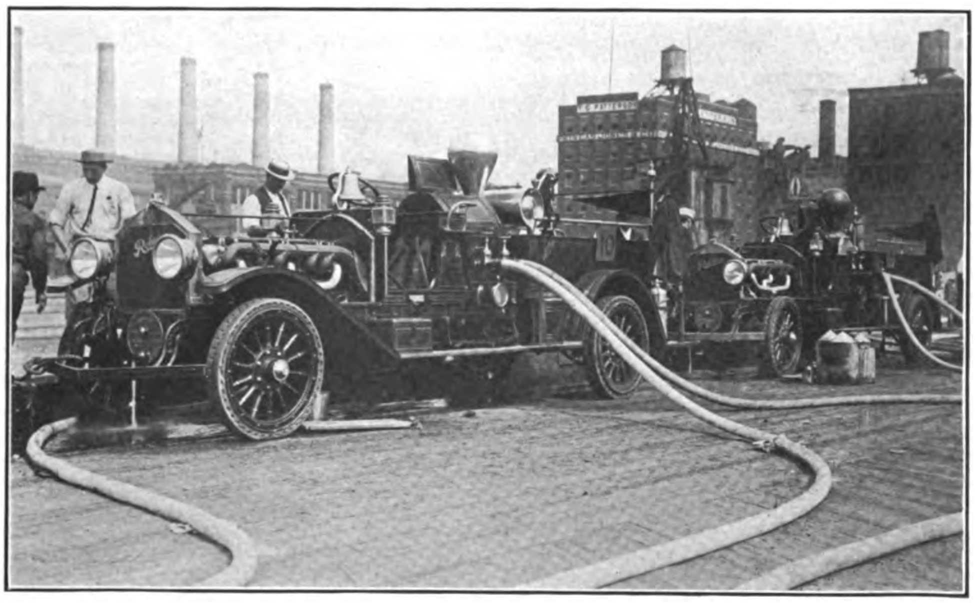
The convention was convened at noon, Labor Day, when President H. F. Magee of Dallas, Tex., called the delegates to order. Following invocation by Chaplain Handel of the New York fire department, Chief John Kenlon of New York City introduced Fire Commissioner Joseph Johnson of New York, who welcomed the firemen, and response was made by Chief Charles H. Henderson of Bradford, Penn. There were short addresses by Chief Kenlon, Chief M. J. Meier, Arthur R. Dyer and Major E. C. Walker, these three gentlemen being made honorary members of the association. W. H. Johnson, former chief of the Philadelphia, Penn., department, who is one of the two survivors of the founders of the association, was introduced to the delegates at the afternoon session, and a letter was ordered sent to Thomas B. Rowland of Norfolk, Va., who shared with Mr. Johnson the honor of being a founder. At this session the first paper was read by Chief A. V. Bennett of Birmingham, Ala., on "Motor Apparatus, Its Durability, Efficiency and Economy of Operation," which was generally in advocacy of self-propelled equipment, emphasizing the greater efficiency and economy through its use, and making comparative statements of possibilities.

Chief Bennett's Address.

"The world does not evolve or revolve backwards," said Helen Kellar, the blind and deaf genius. We who have eyes to see and ears to hear are forced to appreciate the wisdom of this observation. For, at the present time, in this "Twentieth Century," we stand in the midst of a very maelstrom of action and progress. Our every word, our every thought and action should mean a step forward. The world, which for ages has been the slave of ignorance and superstition, is at last being freed by the dissemination of knowledge. The nations have been awakened from their sleep, and the sun rays of truth are piercing the innermost nooks and corners of our world.

This awakening, this realization of things undreamed of 50 years ago, is in a great part due to the advancement of science. Where 100 years ago stretched the unbroken wilderness and the long silence, only now and then broken by the battle cry of the savage, or the voices of the forest, there now rise cities of such magnitude, of such grandeur, that even Aladdin with his magic lamp could not conceive. The ocean, formerly a place of mythical monsters and unknown dangers, has now become the pathway of men, and giant greyhounds, with all the luxury and pomp of a metropolis, sail the main and well nigh unite the shores of two worlds.

The mountain fastnesses of the Rockies and the Andes have been penetrated by creeping, shining bands of steel, and the highest promontories of the Alps now resound with the footsteps of men. The forces of nature are being harnessed and the very elements themselvs drawn upon for power. The rushing waters of the cataract, the dormant power of oil, are being utilized to work for men. Every nook and cranny of the earth



Two Robinson Six-Cylinder Pumps, the 900-Gallon Monarch in Front and the 750-Gallon Jumbo in the Rear, During the Second Period of the Test.

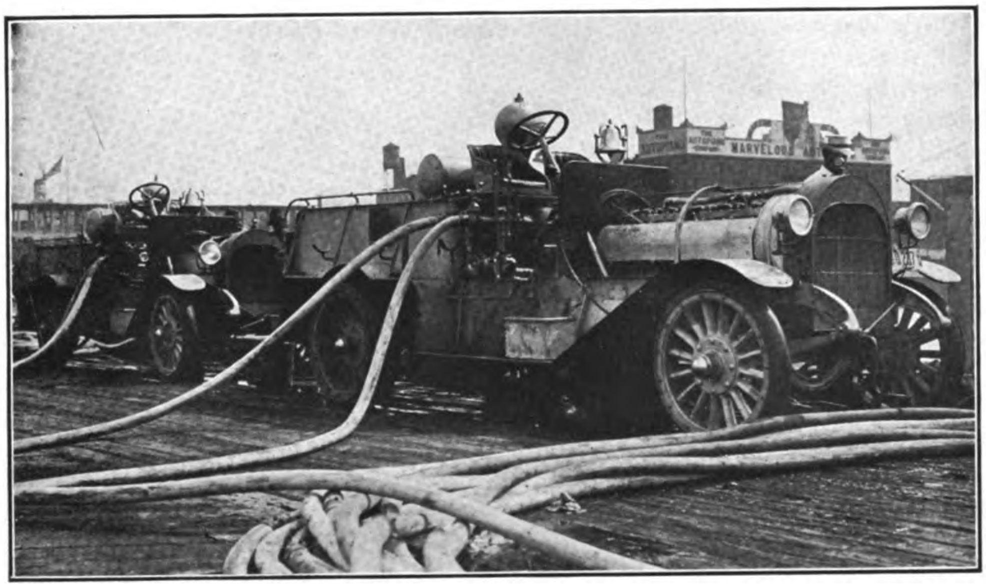
has responded in sweet harmony when the sympathetic chord of "mother nature's" heart was sounded by the instrument of knowledge. Not only in the progressive countries of America; not only in the old civilization of Europe; but even in the Orient, where legend and mystery still haunt the air; even on the trackless deserts of the Sahara, with lonely caravans travelling to the lands of the "rising sun" has the light of advancement penetrated.

Through sublime self-sacrifice and heroism, through bitter pain and struggles, the relentless ambition of man has carried him forward to the furthermost ends of the earth; crossing the barriers of snow and plowing through the mountains of everlasting ice, man has advanced to the very poles themselves.

With this wonderful progress of science, it is not at all surprising that man should be confronted by new difficulties, and by new problems of living. For many years the trend of population has been toward the city, and, as a result, there now arise skyscrapers, which are veritable beehives of human habitation. Giant commercial and manufacturing establishments, tenements and apartment houses are representatives of the new order of construction.

In the old days, when three or four stories were considered the limit, as far as height was concerned, when the houses were built farther apart, when congestion was not so acute, fire fighting was a far different problem from that of today. Progress brought about these new conditions, and it devolved on the same forces to bring the fire department up to the standard by which it would be able to meet the added difficulties. Just as the problems of streets, sanitation and water were met, so did the inventive genius of the times find a solution for the fire fighter, which is evidenced by the aerial ladder, by the water tower, by the powerful high pressure streams, and the various other devices with which we are all entirely familiar.

The desperate rivalry existing between our cities and their mad race to excel their neighbor in population has prompted the extension of the corporate limits from time to time so as to include vast tracts of sparsely settled territory. This, together with the automobile and the trolley car, has introduced a new condition and developed new difficulties for those who were charged with the duty of furnishing fire protection.



Two Nott Pumps, the Six-Cylinder 800-Gallon Machine in the Foreground and the Four-Cylinder 600-Gallon Engine in the Background.

The automobile has enabled the man of wealth to establish a home in the outlying districts, where he may enjoy the comforts of country life and still be near the scene of his daily activity. The trolley car has made it possible for the man of moderate means to establish himself in the suburbs, where he and his family can live in surroundings that would cost him twice as much were his home in the heart of the city.

The country and suburban movements have grown to tremendous proportions during the past few years, and at the present time we are experiencing the heyday of their popularity. The people who have become commuters and still reside in the city, are as much entitled to fire protection as those who reside in the heart of the congested district. In an effort to meet these new conditions, even those municipalities that were erecting new fire stations, and providing additional men and equipment each year, still found themselves confronted with vast expanses of territory that was too far to be reached in time to render efficient service with the horse drawn machine.

To provide means of transporting men and appliances over larger areas fast enough to do successful fire fighting; to provide efficient fire protection for vast stretches of sparsely settled territory, was a problem that again called into service the inventive genius, who, after years of earnest effort, hardship and disappointment, and the expenditure of huge sums of money by the manufacturer, has at last succeeded in giving us the modern, efficient and reliable self-propelled fire apparatus.

The motorizing of a fire department, however, like all radical changes from an established custom, is fraught with many difficulties, and means far more than merely consigning the faithful fire horse to green pastures, and substituting the tireless machine to perform his duty. One of the first, and perhaps the greatest problems with which you are confronted, is the proper training of men to operate the machines successfully. This is especially true of cities that are too small, or for other reasons, are unable to establish and maintain regular training schools.

To the average citizen who sees our streets thronged with automobiles driven by women and children and irresponsible men, the driving of a piece of motor fire apparatus to a fire is an act of small consequence, and requiring little ability or training. Such, however, is not the case, as is evidenced by the many accidents, fatal and otherwise, that have occurred throughout our country since the introduction of the motor machine.

In the first place, your motor fire apparatus driver is a fireman, animated by all the enthusiasm that permeates the profession. This prompts the desire to reach the scene of fire at the earliest possible moment, that he and his company may give the best account of themselves in the fight which is to be made. This enthusiasm, which, of course, must not be destroyed, has a tendency to recklessness, and the reckless driving of a heavy piece of motor fire apparatus through crowded streets is dangerous to the public and ruinous to the machine, and sooner or later results disastrously.

After you have succeeded in training a member of your department to be a careful and successful driver of your motor machine, you have taught him a new trade, and his services are immediately in demand by owners of commercial vehicles, who are in position to pay better salaries or to offer shorter hours, with the result that your best men are often lost to your department when their services are most valuable.

The useless racing of the engine while the car is standing; the engaging of the clutch with the engine racing in starting the car, causing extreme and unnecessary strain on every part of the apparatus, even to twisting the frame work; the engaging of the transmission gears before the clutch has ceased to revolve, and the engaging of the reverse gear while the car is in forward motion; the too rapid driving of machine to the immediate scene of the fire, or to quarters on returning, necessitating the too rigid application of brakes, subjecting the car to useless strain and costly repairs to wheels and tires; the reckless driving of the machine around street corners, causing unnecessary strain on all the parts, inducing skidding and resulting in many unnecessary accidents; fast driving over cobblestones, grade crossings and rough streets, which tends to crystallize axles, steering knuckles, etc., are a few of the things that your inexperienced driver is apt to do. In the motorizing of your fire department, many other problems are to be solved, but the durability, efficiency and economy of operation of your machine depend almost entirely on the care, judgment and skill of the driver in the handling of the car.

The durability of the motor machine, if properly handled, should be almost indefinite, since its radius of action is comparatively small, and its mileage a year in many instances less than 100 miles, and in very few cases exceeding 500 miles. In the majority of alarms answered the entire distance to and from the fire is over paved or well kept streets, which reduces the wear and tear of the machine to a minimum.

Efficiency.

The motor's chief claim to efficiency is its speed and ability to continue indefinitely without tiring. By its speed we are enabled to extend its radius of action over a territory two or three times as great as that covered by the horse drawn machine and still obtain efficient fire service.

We have, on several occasions, covered a distance of three or four miles with our motor machines and extinguished fires with small damage, originating in ordinary frame residences. Of course, this does not mean that the number of companies or the number of men employed before the installation of the motor should be reduced, for in the handling of large fires, in your congested district, you will unquestionably require the services of as many men and as many pieces of apparatus as formerly.

Nor does the motorizing of your department mean that you will only be required to establish engine houses in a radius of three or four miles of each other in your densely populated residence section. But it should mean more efficient service in all sections of your city and that engine houses will not be required in the immediate vicinity in order to furnish protection to your sparsely settled territory.

The motor machine perhaps in no way more clearly demonstrates its efficiency than in the prompt manner in which second alarm companies reach the scene of the fire. This is especially true in the residential sections of the smaller cities, where second alarm companies have a great distance to trav-

erse. Their prompt arrival on the scene is always a source of gratification to the officer in charge.

Reliability.

The reliability of motor apparatus has been a question of grave concern among fire department officials and others interested in fire protection. Such questions, as, Will the motor negotiate steep hills? or muddy streets? or deep sand? soft and hard snow? have been the subject of much correspondence between officials whose cities had already bought, and those who were contemplating buying the modern equipment.

By actual tests the motor has proven to be as free from break downs and delays, if properly handled, as the horse drawn machine, and should be considered equally as reliable and trustworthy under all circumstances. In negotiating hills your motor will climb grades with comparative ease that it is impossible to ascend with the horse drawn machine. In muddy streets, through sand or snow, if your motor machine can get traction it will plow through bad stretches where one pair of horses hauling your heavy fire apparatus would be sure to fail.

Economy of Operation.

The cost of operating motor fire apparatus is rather difficult to determine accurately as yet, because of the uncertainty of depreciation and necessary repairs due to actual wear and tear. The expense of operation, however, is largely controlled by the ability and care of the driver in the handling of your machine, who will raise the cost to abnormal proportions, or lower it decidedly below that of the horse drawn machine doing the same work, proportionately, as he exercises skill and judgment in his driving.

Tire equipment will necessarily be one of the factors in the cost of operation. The pneumatic tire possesses many advantages, such as resiliency and traction; is less liable to skid, and protects the machine against rough driving; but the ever-present danger of a puncture or blow-out, often putting the machine out of commission to change or repair tires, and the expense of frequent replacements render the pneumatic far from being the ideal tire.

The solid tire too has its advantages and disadvantages. The danger of punctures and blow-outs is entirely eliminated, and this equipment is durable and thoroughly reliable. With dual tires on the rear wheels, sufficient traction is obtained to carry the machine where you might reasonably expect to go, but the vibration to which your machine is subjected while being rapidly driven, especially over rough streets, necessitates many repairs and sooner or later sends the car to the shop for a general overhauling.

The cushion tire combines many of the good qualities of both the pneumatic and the solid, but does not possess the durability of the latter, and is correspondingly more expensive.

The actual cost of operating motor apparatus, exclusive of wear and tear and depreciation, is very small as compared with the horse drawn machine.

We have cars in service on which the cost of operation has averaged less than $3 a month since their installation, which was nearly three years ago. We also have machines in service which during the last 18 months have not required one penny's worth of repairs.

George W. Booth of the National Board of Fire Underwriters submitted a report to the National Fire Protection Association this year in which he embodied a table of comparative cost between the horse drawn and motor driven machines, which is so nearly correct that I am taking the liberty of reproducing it, as follows:

Hose Wagon—Horse Drawn.

	Cost a year.
Cost, $2000.	
Interest at 4½ per cent	$90
Depreciation (based on life of 25 years)	45
Repairs and tires	30
Total	$165

Steam Fire Engine.

Cost, $5500.	
Interest at 4½ per cent	$247
Depreciation (based on life of 25 years)	124
One new boiler and general overhauling—$2000	84
Tires and repairs	70
Total yearly cost for engine	$525
Interest, depreciation and coal for heater	90
Total	$615

Two Horses.

Cost, $600.	
Interest at 4½ per cent	$27
Depreciation (based on life of seven years)	60
Shoeing	90
Veterinary	25
Harness	6
Forage	300
Total	$508

Two-Wheel Tractor.

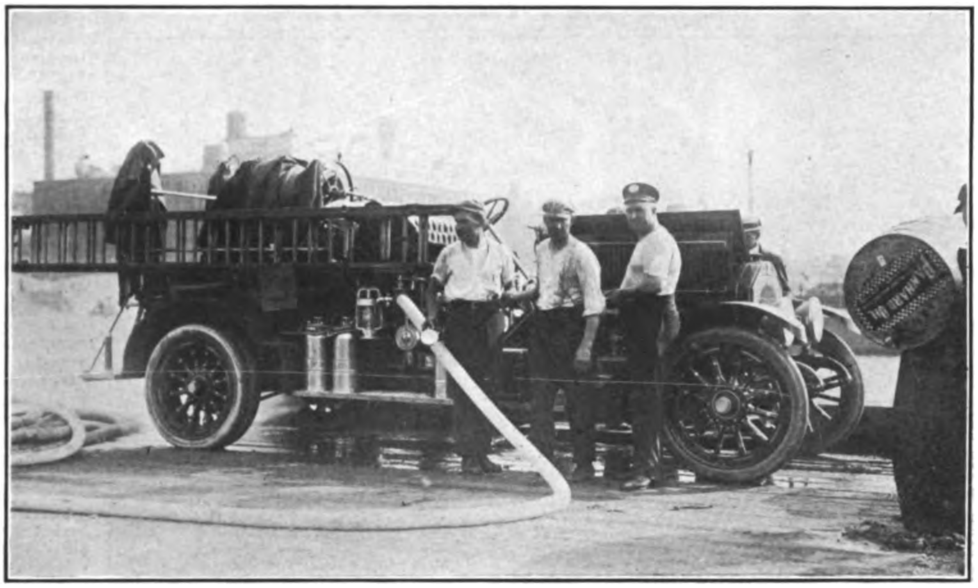
Cost, $4000.	
Interest at 4½ per cent	$180
Depreciation (based on life of 25 years)	90
Repairs (nine cents a mile)	45
Tires	40
Operating (seven cents a mile)	35
Total	$390

Automobile Hose Wagon.

Cost, $5000.	
Interest at 4½ per cent	$225
Depreciation (based on life of 25 years)	112
Repairs (nine cents a mile)	45
Tires	60
Operating (seven cents a mile)	35
Total	$477

Automobile Combination Pumping Engine and Hose Wagon "Z."

Cost, $9000.	
Interest at 4½ per cent	$405
Depreciation (based on life of 25 years)	202
Tires	80
Repairs (10 cents a mile)	50
Operation (eight cents a mile)	40
Total	$777



American-La France Six-Cylinder 700-Gallon Pump with Its Crew and an Observer Working to Its Greatest Capacity.

Steam Fire Engine with Tractor.

Cost, $9000.	
Interest at 4½ per cent	$405
Depreciation (based on life of 25 years)	202
New boiler, etc	84
Heater cost	90
Repairs and tires	125
Operation of tractor	35
Total	$941

Summary.

Steam fire engine, horse drawn	$1125
Hose wagon, horse drawn	675
Total	$1800
Steam fire engine and tractor	$940
Automobile hose wagon	480
Total	$1420
Automobile combination pumping engine and hose wagon	$780
Automobile hose wagon	480

Cost of operating at fires for five-hour run, with two good streams:

Steam fire engine—Four tons of coal at $5	$20
Gasoline engine—60 gallons gasoline at 17 cents	10

It will be noted that Mr. Booth uses as a basis a yearly total of 500 miles to be covered by each type of machine. In the average city this is at least twice the mileage that would be made, taking the entire number of machines in service as a whole. And the cost of operation will be correspondingly reduced with the motor driven, but would not be with the horse-

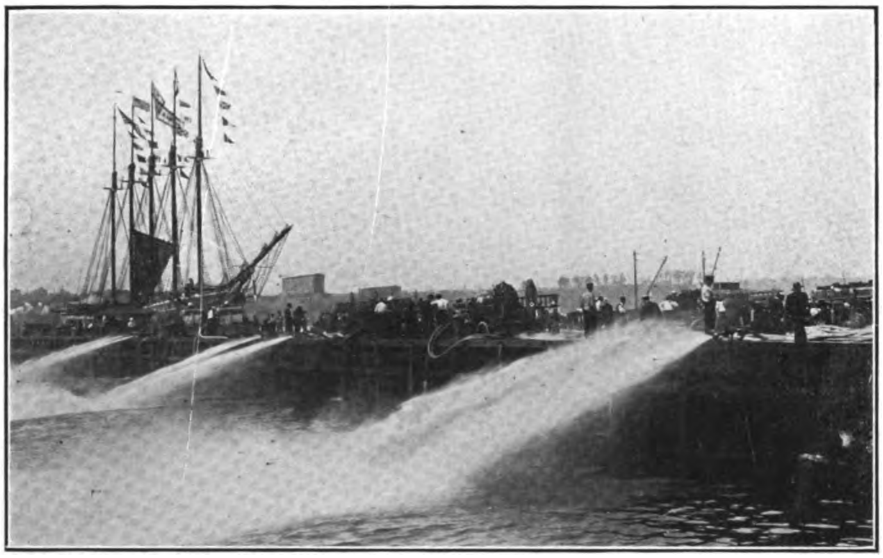
drawn machine, as the cost of maintenance is about the same for the horse, whether he answers an alarm or stands in quarters.

The march of progress cannot be halted. Self-propelled fire apparatus, as the product of this progress, is rapidly making mighty inroads on the old methods of the fire fighting service. The growing favor of the motor car is in no way more concretely illustrated than in the recital of the fact that my home city, Birmingham, Ala., less than three years ago, with its 24 pieces of motor driven fire apparatus, ranked first as far as equipment of this kind in relation to population was concerned. But, today, what a change! With the same number of pieces in service she has dropped down to 36 in the list.

This wonderful increase in the use of the new equipment is not due to a mere desire to get in line, to be more modern than our neighbor cities, but to far more substantial reasons. It has been brought about because it is more economical; because it is more sanitary; because immediately after our longest, hardest runs, it is ready to respond to the next call; because it will continue indefinitely without tiring. These facts are stronger than all the eulogistic tributes that might be paid the new type vehicle. They are based on every day use and experience. They stand out indisputable, uncontrovertible, invincible, and lead to one inevitable conclusion, motor driven fire apparatus is not a luxury, but a vital necessity.

At the conclusion of brief discussion the following paper on "Motor Apparatus as Used in the London Fire Brigade, 1912," was read by Arthur Reginald Dyer of the London fire department:

Before entering on the subject of motor fire appliances, a brief explanation of the system adopted in London of dispatching appliances in response to calls is subjoined, in order that the conference may understand the duties required from the various types adopted.



Streams of Water, Two Thrown by Each Engine, During the Six-Hour Test, When the Pumping Was Made at a Pressure of 120 Pounds.

The area to be protected is 117 square miles, which, with the exception of the public parks and some small areas at the extremities of the Metropolis, is entirely covered with buildings. There are at present for this area 85 land fire stations and three floating stations; of the former 18 are entirely equipped with motors and 12 partially so.

Each station is equipped with a fire escape van carrying a ladder capable of being extended to at least 50 feet and also furnished with supplementary ladders, hose and tools for getting to work from hydrants, and a cylinder holding about 30 gallons of water, fitted with 180 feet of rubber garden hose, .75 inch inside diameter, for extinguishing small fires. This appliance, the crew of which is on duty night and day, is ready for an instantaneous turn-out and only attends fires on the ground immediately protected by the station, the distance it may travel to fires rarely exceeds one mile. The yearly mileage of escape vans is about 600 a machine.

Most stations are also equipped with an engine or motor pump, and in a few localities with two engines, all of which carry hose, etc. These engines besides attending fires in the vicinity of the stations at which they are kept, are considered available for service at any fire in the area protected. The yearly mileage may be taken at 1200 a machine, but in addition they perform heavy duty pumping at fires sometimes for 24 hours without intermission.

Stations in localities where there are many high or warehouse buildings, are equipped with long ladders extending from 75 to 90 feet; these appliances while intended, generally speaking, for attending local calls, are considered available in case of serious fires in high buildings within a radius of about five miles. The yearly mileage run does not exceed 1000 a machine.

Other motor appliances in use are lorries (trucks) for carrying on from the central stations, coal and oil fuel for the steam fire engines, petrol (gasoline) for motor pumps, and also additional hose and acetylene water lights, etc., to large fires, and delivering stores regularly to stations; tenders for taking on the principal officers and their orderlies to fires, and also self-contained oxygen smoke helmets, cellar pipes, marine torches (acetylene), etc.; instruction tenders for training the men undergoing instruction in motor driving. These are not the oldest motor appliances available, but modern ones with chassis similar to those in use for pumps, escape vans, etc.

Motor cars for officers have been in use since 1901 and shortly after that an attempt was made to draw an existing land steam fire engine by a motor tractor, the front axle being removed, making altogether a six-wheeled appliance. It was found impossible, however, to travel at sufficiently high speeds with this without undue skidding and the principle was abandoned.

In 1902 an existing steam fire engine was converted to a motor engine by providing a separate engine for propulsion, the steam being supplied by the fire engine boiler; after a time, however, this was abandoned and the appliance was reconstructed for horse traction.

The first success in replacing horsed fire engines and horsed escape vans by mechanically driven vehicles occurred in 1905-1906, when steam motor fire engines and petrol motor escape vans were obtained. With the former it was found that as the appliance had to be ready for an immediate turn-out, a pressure from 80 to 100 pounds a square inch had to be maintained in the boiler, and owing to the excessive vibration on this type of boiler on the road, necessitating considerable repairs, and also to the large expense incurred in maintaining this pressure by gas, the steam system was abandoned.

With regard to the petrol motor escape vans, the first supplied only gave moderate satisfaction as manufacturers generally had no experience in the running of motors (weighing about 11,200 pounds with load) at speeds exceeding 20 miles an hour to guide them, the principal defects being under-tiring, want of sufficient strength in the fittings to withstand the excessive vibration, and inadequate springing. Indeed, prior to 1910 it was considered necessary to have one spare escape van for every one on duty in order to maintain an efficient service, whereas at present only one in five motor escape vans or motor pumps is necessary. The experience with early petrol fire engines fitted with pumps was somewhat similar.

From the first introduction of heavy engines capable of high speed the problem of providing a satisfactory non-skid engaged attention. Some mitigation of the inconvenience was found by utilizing chains festooned diagonally across the tires, but considerable damage was caused to the rubber, which, when worn, allowed the chains to come in contact with the iron rims, causing the non-skid chains to break and not unfrequently jam in the driving chains, or to allow the loose ends to tear the mudguards, etc. Other devices were tried to check the tendency to skid, such as studded leather covers and transverse bands of steel studded balata belting fitted into slots cut into the rubber of the tire. The latter were found to be most effective when tires and bands were new, but gave endless trouble when partly worn.

One motor pump was fitted experimentally with a gyroscope behind the radiator, but it was removed as a swaying motion was set up when travelling at high speeds. In addition to this the steering was rendered uncertain.

One appliance has run for a year without non-skids, but with soft rubber tires of flat tread and extra wide section, single on front wheels, twin on hind wheels; although no skidding has taken place there is still some doubt if fire engines can be safely run under all conditions in London without some non-skid attachment.

Front wheel brakes were tried on the appliances supplied by different manufacturers in 1910 in order (it was hoped) to obviate the effects of skidding, but while satisfactory results were obtained on tests they were found unsuitable in practise and have now been removed from the appliances and rear wheel or differential brakes fitted in lieu.

The difficulties formerly experienced have now been fairly overcome as follows: (a) By careful training and the continued experience of drivers; (b) by allowing greater cross section in tires; (c) by extra heavy leather steel studded covers fitted on two wheels only, one front wheel and one hind wheel.

The author has up to now referred only to early attempts to introduce motor traction in the place of horses and the experience gained was extremely valuable both to the fire brigade officials and the manufacturers.

It is now proposed to deal only with what may be termed motor appliances at present in use:

(1) Escape vans.
(2) Pumps.
(3) Turntable ladders.
(4) Lorries.
(5) Tenders.
(6) Cars.

Escape Vans.

Perhaps the most successful type of appliance to be introduced has been the electric motor escape van, for service in localities where only moderate gradients are encountered, the first of this kind being obtained in 1911.

The power is provided by a battery of 84 cells of 195 ampere-hours capacity, giving a normal running output of about 30 horsepower. The appliance runs about 30 miles on one charge if necessary, but owing to the nature of its service it stands fully charged ready to give out the maximum output on receipt of a call.

The motors are in the front wheels, the fields being fixed to the stub axle around which the armature revolves with the wheel. The tires are single five-inch on all wheels.

There are electric brakes on the front wheel motors which are valuable in emergencies, while two mechanical brakes on the rear wheels are sufficient under ordinary circumstances. The control is of the series-parallel type with five notches forward and reverse, and two brake positions.

The weight of the appliance ready for running, but without ladders, hose and small gear and men, does not exceed 8300 pounds. The total weight of the machine complete being about 11,800 pounds. A speed of 25 miles an hour is maintained with full load on a level and good road, and the machine is capable of ascending a gradient of one in eight fully laden, at a speed of about six mph or a moderate gradient at 15 mph.

The weight of the appliance fully laden is about 600 pounds more than a corresponding petrol van. Undoubtedly petrol motor escape vans are required for localities where stiff gradients have to be encountered.

The type found satisfactory has the following general features: Four-cylinder engine, five-inch bore by 5.5-inch stroke, giving about 50 brake horsepower; double ignition, Bosch magneto and accumulator and coil; speed about 30 miles an hour.

The engine is started up in the station every four hours, day and night. Where the engine room at the station is not warmed with hot water or gas radiators, electric heaters are hung over the front of the radiator to warm the engine and keep it ready for an immediate start in cold weather.

The appliance weighs about 11,200 pounds fully laden and has 4.5-inch tires on front wheels and 5.5 on rear.

Pumps.

A modern petrol pump used in the London fire brigade has a four-cylinder engine, five-inch bore and 7.125-inch stroke, giving 58 brake horsepower at 1000 revolutions a minute and 65 bhp at 1100 rpm. Speed, 30-40 mph. Weight, about 11,200 pounds fully laden with men, gear and hose. Tires are single 4.5-inch front and single 5.5-inch rear. The pump is centrifugal (usually termed turbine) and geared up from the engine. It is placed at the rear of the appliance and can be controlled from there or from the driver's seat.

It is now found that for London the two, three or four-stage centrifugal pump is capable of fulfilling all the required conditions and only this type has latterly been specified. The pump gives an output of 500 English gallons (American, 600 gallons,) a minute at a working pressure of over 120 pounds a square inch.

There is a considerable controversy among fire engineers in Great Britain as to whether the reciprocating or centrifugal pump is the most suitable for the duty required of fire engines. The mechanical efficiency of the reciprocating pump is 10 to 15 per cent. higher than the centrifugal; the pump can run slower when discharging a small quantity of water at high pressure and can pick up its own water when drawing from a canal or dock without the aid of a vacuum pump, which is necessary for the latter.

The centrifugal pump has to run fast in order to obtain even a small quantity at high pressure. On the other hand when delivering at lower pressures a larger volume can be delivered than from the reciprocating.

One great advantage of the centrifugal pump is the possibility of working two pumps in series when a high pressure is required, or in parallel when a large volume is required for one jet. Under the former conditions an efficient jet was thrown over the top of St. Paul's Cathedral 340 feet above pavement level. The jets commonly obtained from standard large sized American steam fire engines can also be obtained by working two of the smaller capacity motor pumps as described above.

In London it is necessary that in addition to the pump at least 600 feet of rubber lined canvas hose 2.75 inches inside diameter, besides the necessary small gear (see appendix), and five men must be carried. The speed of the appliance is greater than that of motor escape vans.

Although at present in the outlying suburban stations smaller horsed steam fire engines are stationed than those in the central area stations where the fire risk is greater, it has been found best to equip the former stations with the same sized motor pump as in use elsewhere, as the additional pumping capacity is available when an engine is ordered on to large fires, also the additional distance to be covered need not be considered as in the case of horsed engines.

At present the brigade is only equipped with two motor turntable long ladders. These can be extended to a height of 90 feet and can be safely used as a water tower at a height of 60 feet. In both cases the system of propulsion is by electric storage batteries and hub motors in the wheels. In one design the wheel motors are interchangeable with those on the motor vans for carrying escapes and drive on the front wheels. In another type the battery is of the same capacity and manufacture, but the motors are fitted to the rear wheels.

It is not considered necessary to specify for these appliances to travel at a speed of more than 20 mph. The total weight of the appliance with ladders is about 13,800 pounds.

It is probable that by adopting motor long ladders a number of the existing horsed long ladders will be dispensed with two of which are being adapted for electric traction.

Lorries.

The first lorry to be procured was a standard five-ton (11,200 pounds) machine from one of the largest lorry builders. It is fitted with a four-cylinder engine 5.5-inch bore and 6.5-inch stroke, having an output of 55 bhp at 1000 rpm, and is capable of a speed of 30 mph. It is fitted with five-inch tires on front wheels and twin five-inch on rear. No non-skids are provided. A covered hood is fixed.

A second lorry has been ordered. This will be one of the standard three-ton (6720 pounds) type, similar in most respects to the larger machine. It will have a four-cylinder engine, 4.75-inch bore and five-inch stroke, giving an output of 45 bhp at 1000 rpm. This machine will be kept at the chief station in one of the districts and will be used in a similar manner to the other appliance.

Motor Tenders.

Those at present in use for carrying principal officers to fires and other work are standard chassis by well known makers. In one case large pneumatic tires 35.5 by 5.5 inches (895x135 mm) are fitted, with detachable rims. On this machine four men are carried, besides the gear mentioned previously, the total weight being 4410 pounds, and no trouble has been experienced with the pneumatic tires. Indeed, the instruction tender, which is of similar pattern and drive, has also been recently adapted for pneumatic tires instead of solid ones.

Knox Six-Cylinder 600-Gallon Engine with a Pile of Reserve Hose in Front of It—A Typical Scene During the Trials.

At some suburban stations motor tenders are located in addition to the motor escape van, that in the event of the latter being required elsewhere the tender may be at once dispatched with sufficient men, hose, hook ladders, etc.

Motor Cars.

The cars in use, of which there are 13, are of standard pattern by well known makers, and are mostly fitted as touring cars. They are used both for inspection work and also for proceeding to fires. The superintendents in each of the six districts are now provided with two-seater touring cars for daily inspection of the stations in their districts, also for taking them on to fires. Smoke helmets are carried in those cars.

The author has not endeavored to enter into details of the appliances, but subjoined are complete specifications of the principal machines to which the makers have to tender, and in connection with this it has been found advisable to restrict the number of types in the service, in order that the drivers when transferred from one appliance to another in the station or district can drive the appliance efficiently. In future endeavors will be made for only machines of one make to be allocated to a station.

In the early days of motors, specifications were drawn up by technical officers of the brigade, but with the exception of details it is now found advisable for the manufacturers to supply their standard type of chassis adopted to the conditions of the London fire brigade, as they are in a position to replace any parts instantly from stock.

Perhaps one of the most important points with regard to the application of motors for fire brigade work is the question

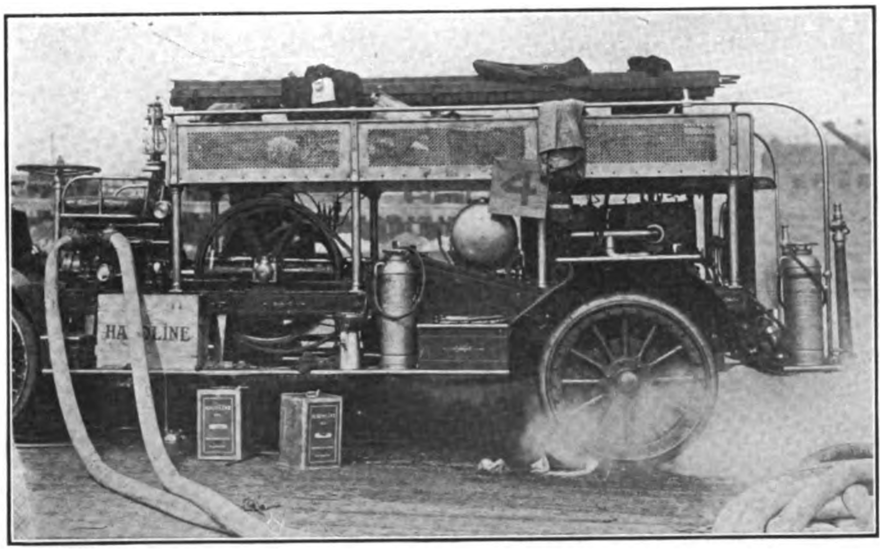
of the cost compared to horsed appliances. In the early stages it would not have been correct to say that any saving was shown in favor of motors, indeed the reverse was the case, but with the improved standard commercial type chassis which has been adopted, and the continued experience of the drivers, there is undoubtedly a saving effected by motor appliances.

The London fire brigade owns no horses. They are hired from the contractors at an average rate of £70 a year a horse, this sum includes bedding, fodder and harness; the contractor also takes all risks.

The following figures give comparison between the cost in maintenance of horsed and modern motor appliances, the repayment of cost of horsed appliances being spread over 25 years and for motors 10 years:

Horsed Appliances.

Appliance	Average first cost	Depreciation 25 years and interest at 3.5 per cent.	Repairs	Gas	Oil fuel	Horses, 2 at £70 each	Average annual maintenance
Steam fire engine	£350	£20. 7.4	£14	£32	£8	£140	£214. 7.4
Escape vans	65	3.15.8	9	..	..	140	152.15.8



Luitwieler Four-Cylinder 600-Gallon Engine, the Smallest in the Trials—A Novel Construction with the Motor at the Rear and the Pump Forward.

Motor Appliances.

Appliance	Average first cost	Depreciation (10 years) and interest at 3.5 per cent.	Average annual cost, repairs, including tires, etc.	Average annual cost, petrol, lubricating oil, grease, etc., and accessories	Total	Average annual mileage an appliance	Average running cost a mile in pence excluding depreciation and interest
Pumps	£900	£110	£40	£25	£175	1032	15.1
Petrol escape vans	750	90	30	15	135	522	20.6
Electric Current.							
Electric escape vans	£950	£115	£25	£8	£148	659	12.0

From the above it will be seen approximately that the saving with motor pumps is about £40 per machine per annum, petrol escape vans about £17, and for electric escape vans about £5 as compared with similar horsed appliances.

The total number of motor appliances required to complete the conversion of the brigade from horsed to motor traction in addition to those at present in the brigade and on order for this year will be as follows:

Escape vans (petrol or petrol-electric)	31
Escape vans (electric)	32
Motor pumps (petrol or petrol-electric)	64
Motor turntable ladders	23
Motor lorries	9
Motor canteen vans	1
Motor cars	2
Total	162

It is estimated that the cost for the above future appliances will be about £160,000.

The present equipment of the brigade, including the appliances on order is as follows:

Escape vans (petrol)	22
Escape vans (electric)	11
Motor pumps (petrol)	30
Motor turntable ladders	4
Motor lorries	2
Motor tenders	5
Motor cars	13
Total number of appliances	87
The ultimate total number will be	249

There are also in use two motor fire boats, as well as two steam driven vessels.

At the session the afternoon of the second day a paper on "The Motor Pumping Engine, Its Defects and Cost of Maintenance," was read by Charles S. Demarest, chief of construction of New York fire department, who has charge of the repair department of the New York department. Mr. Demarest has had a wide experience with every form of equipment and since the use of motor apparatus by the city of New York he has made a careful study of the requirements for maintenance. This has entailed observation of the possibilities for failure and damage in the service in the second largest city in the world, where fire protection has been probably more carefully considered than elsewhere in America. The metropolitan equipment must necessarily be subjected to greater and harder service than that in any other municipality, and with the exceedingly high structures, the large area, the mediocre streets, the congested traffic, and the very large number of fires, it must be kept at maximum efficiency. The maintenance of this apparatus has been Mr. Demarest's work for years, and his paper dealt with what he believes to be absolutely essential as a standard. The paper follows:

Mr. President and Members of the International Association of Fire Engineers:

Although an endeavor has been made to cover the subject assigned to me, it is probable that you will agree with me, after the completion of this paper, that the title should have been changed to "Some Defects and Troubles Experienced in Repairing Motor Fire Apparatus."

The motor pumping engine is yet a broad subject for discussion, but when we consider the standards set for it by the steam fire engine, which required a period of 60 years to bring it to its present state of perfection, we must all agree that the development of the motor pumping engine in the past two or three years has been wonderful. The New York department has so few pieces of motor pumping apparatus that actual service conditions will not be discussed to any large extent; however, experience with the large amount of other motor fire apparatus, and the rigid inspection of motor pumping engines made while taking part in tests of about every make on the market, have convinced the writer that the motor pumping engine cannot be classed, with its present design, as giving the same reliability as the steamer, although its performance in most every other respect has about equalled that of the steamer for the period of time during which they were run. We are all familiar with the performances and reliability of the steamer, and there is no reason in my mind why the motor pumping engine should not be just as reliable for fire service if the manufacturer would make a more exhaustive study of the conditions that actually exist at fires.

A motor behaves well in clear weather and many behave well on the road in a severe rain storm, but it has been our experience with several pieces of apparatus that they could not continue in service under conditions of rain and water liable to be encountered in fire service. Even with pleasure vehicles trouble is encountered; on July 28 of this year we had a severe rain storm which lasted for about one hour; during that storm,

between 59th and 115th street, there were six automobiles that were stalled, due to the ignition systems not being water proof or not being properly protected against a severe rain storm.

It is not an unusual condition in fire service to have eight to 25 engines at work, with hose lines running on all sides and probably underneath fire apparatus; a burst hose near a pumping engine, a deflected stream from a nozzle or heavy spray may completely drench a motor. Now, is the motor pumping engine, its magneto, ignition system and carburetor, so well housed that it will continue to perform under such conditions? There is no reason why these important parts of the motor cannot be so housed that the chances of the motor going out of commission are very remote when hit with a stream of water. It may be possible that a motor must have a certain amount of air current while running on the road, but this does not apply when the motor is pumping water, as all motor pumping engines are so constructed that you may regulate the cooling water from the fire pumps.

Recently the motor for a water tower could not be started after several hours service at a fire; on investigation it was found the spark coil, one of the best on the market, had got wet and would not operate; the water in this case had worked through the front, indicating the need of not only water proofing all parts of the spark coil, but of housing the front in such a way that water cannot reach it. If this had been a motor pumping engine it would have been put out of service, probably at the most critical stage of the fire.

Water proof magnetos are on the market, but do we get them on fire apparatus? Very few of the present makes are equipped with them, yet we learn of pumping engines failing at test because of water from leaky radiators being sprayed on them, and we know severe rains will put them out of service. Spark plugs, heated by long runs, have been known to have the porcelain insulation so badly cracked by water as to short circuit. The effect of water blowing into the carburetor would be serious, but no effort has been made to eliminate the danger and many are set in such a way as to invite water. It has been argued that because of the hood, the probability of water getting to these parts is very small. This cannot be accepted as a satisfactory statement with the present apparatus on the market; there is not today any motor pumping engine which can run for several hours without having to lift the hood to oil some moving part or refill an oil tank. In addition to having the above parts completely water proof, why should we not have all other parts so designed as not to have the cover touched during a long run? The carburetor for fire service should have very few adjustments and these adjustments should not become disarranged or have to be changed after properly adjusting. The oiling system should be so designed and located that it would not be necessary to raise the engine hood for oiling purposes while working at a fire.

In the preparation of this paper it was attempted, by tabulating actual daily report sheets kept in the New York repair shop, to obtain some first hand information of both the causes of accidents and repairs and the expenses resulting therefrom. Necessarily, the period over which our records extend is short, as the oldest pieces of automobile apparatus in the department have been in service less than five years, and during the first two years it was repaired mainly by the manufacturer under his guarantee.

One item very much worth looking into is the question of accidents and the comparative cost of repairs from this cause. Much faster speed is made with automobile apparatus and it takes a more experienced man to handle it than to drive horses. In fire department work it is practically impossible to always be sure to have a highly trained man to drive the apparatus, and at the high speeds at which he travels a "green" man is very liable to accident. Even though motor apparatus is more tractible and can be guided through places hard for horse drawn apparatus, the number of accidents due to poor handling is high and indicates a condition which must be overcome.

Our records show a cost of repairs due to accidents of $531 for one of our water towers, and of $757 for one of our pumping engines; these figures are given to show that when accidents occur, the speed and weight of the machine are usually such as to cause considerable damage and result in a large bill for repairs. Because of severity of the damage, it is particularly objectionable to have the apparatus of a complicated type; if you are not equipped to handle the situation the apparatus is out of service for an indefinite time and you may have to send hundreds of miles to get an expert to locate and repair your trouble.

The following figures are of interest, although the time over which the records go, i. e., 2.5 years, is not sufficient to give a true average:

Deputy Chiefs' Runabouts (Six Cars).

Average yearly cost a car for repairs due to accidents....	$44
Average yearly cost a car for other repairs..............	14

Automobile Hose Wagons (Seven).

Average yearly cost a wagon for repairs due to accidents..	45
Average yearly cost a wagon for other repairs............	110

Gasoline-Electric Aerial Ladder Trucks (Three).

Average yearly cost a truck for repairs due to accidents..	82
Average yearly cost a truck for other repairs............	81

These items do not include painting or new tires, which in many cases were necessary and materially increased the cost. Of the cost charged up against hose wagons and the ladder trucks, it was estimated after a careful looking over of the records and time sheets, that at least one-half the cost was due to faulty construction and to poor design.

From the repair standpoint there should be borne in mind three very important factors: No apparatus should be bought which is too complicated for the chauffeur to make minor repairs, or for the foreman of the repair shops to take to pieces and put back again; no apparatus should be purchased which is so built that it is hard to get at its parts and requires a partial or total disassembling to make most repairs, and no machine should be constructed with its parts so heavy that they cannot be readily handled.

That these three features are not always followed is evident to anyone having to do with the repairing of many of those on the market. The cost of repairs in many cases is excessive, due to unnecessary complications. For example, in some apparatus it is necessary to take down the entire transmission and jackshaft housing in order to replace a jackshaft, but if the jackshaft were of the full floating type all this unnecessary labor would be eliminated; in certain types, in order to get at the timing gears the entire motor has to be taken out; to put in a gasket on the exhaust manifold it should not be necessary to take down the steering column and dash; this is faulty construction and should be eliminated. A unit power plant is preferable, as it is not as liable to get out of line and is easier to handle when making repairs, as it can be taken out as a whole or can be taken apart.

The starting dog on the crankshaft should be keyed on as well as fastened with a pin; the shearing off of the pin, which has occurred in several cases where that was the only fastening, has resulted in serious injury to the timing gear.

The Pier During the Pumping Trials, Looking Toward the Head of the Dock, the Engines Being Located Close to the Cap Log at Either Side.

Drip pans should be made more readily removable; in many instances it takes an hour or more to remove this when some minor repair is necessary.

The method of transmitting power from the motor to the pump should be positive in its action and there should be no chance of slippage between the motor and pump when increased pressures are required. Some recent accidents seem to indicate that the driver has gone from full speed ahead direct to reverse; this should not be possible, and usually a simple stop of some kind can be attached without changing the design of the shift.

The multiple disc clutch is unsatisfactory because of the necessity of oiling and oiling just right; the cars so equipped in this department have given a great deal of trouble from these clutches being too dry and the gears being stripped when a change of speed was attempted. To oil and fix this type of clutch usually means putting the car out of service for quite a time and requires the removal of all hose on the apparatus. Although very satisfactory for touring car service, for fire service it should never be used.

Are the steering knuckles, cross steering tubes and their connections made of the best material and of sufficient strength to withstand fire service? With several makes of apparatus they have failed while responding to fires, and this failure is too serious to occur under even very severe conditions; the apparatus is out of service and probably sustains considerable damage, and, more important, the lives of the men are jeopardized. The wheel spindles, steering knuckles, cross steering tubes and their connections to the steering wheel should be stronger than on commercial apparatus, as the road conditions are more severe.

A heavy bumper should be provided on all fire apparatus, and it will more than pay for itself within a short time.

Besides the above, a study of accidents and repairs has

brought out the following:

The oiling systems should be positive and reliable; the gasoline tank should be made of copper and of sufficient capacity to run the engine at full capacity for four or five hours, and gasoline supply to carburetor should be by the gravity system so the tank can be replenished without interrupting the motor. There should be no soldered joints in the gasoline line and this line should have a shut-off close to tank and easily accessible, as well as a drain valve; the gasoline tank on pumping engines should have an arrangement whereby the operator can observe at all times the amount of gasoline in the tank.

The question of combined gasoline-electric drive is approached with limitation, as the manufacturers have gone to large expense in getting up this type of apparatus, presumably to meet the demands of fire chiefs. However, it is the writer's opinion that it is not the logical development and is certainly not desirable for the smaller places, where extensive shop facilities are not available and an electrician cannot be maintained. Besides increasing the first cost to a figure much beyond that for a tractor drawn piece of apparatus, it introduces the complications of extensive electric wiring; few men attached to repair shops can properly care for such apparatus and it is very unlikely that the operator will know even the first principles of maintenance of such apparatus.

As a broad statement, resulting from experience with all types of motor apparatus for fire service, it is evident that if the manufacturers do not pay more attention to their design as affecting reliability and ease of repair, it will be necessary for the fire chiefs to draw up more rigid specifications and detail drawings, which will require the manufacturers to modify their stock plans.

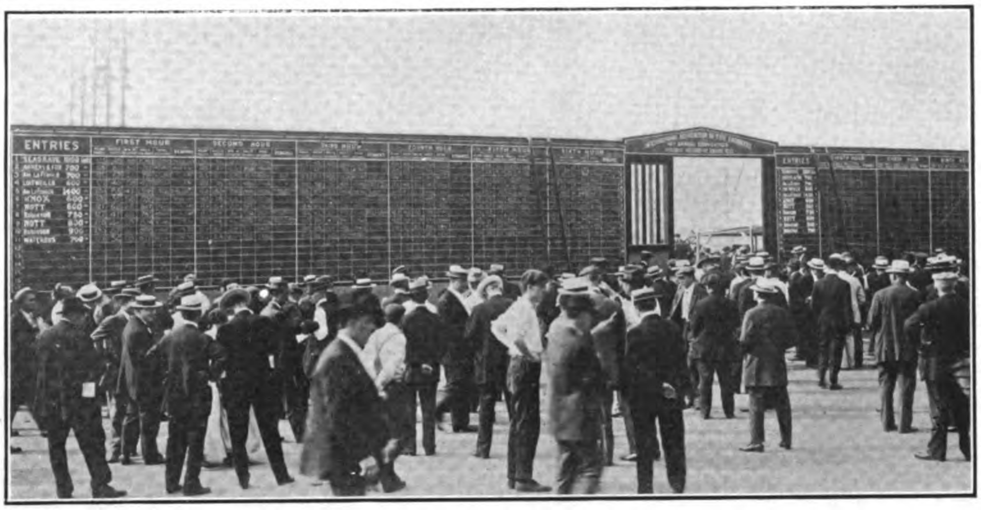
In buying motor fire apparatus, a city, particularly a small or moderate one, should stick to one make that will give the desired results, or at any rate adopt certain things to be standardized and make all bidders put those things on according to your standard. If tractors are bought, they should be required to be interchangeable, the bolted connection, turntable, or whatever is used, to be the same in each. There is no reason why wheels, axles, springs, brakes, carburetors, magnetos, batteries and spark plugs should not be standardized, thus cutting down the extra parts necessary to carry and make it easier to repair the apparatus; this will usually mean the employment of a mechanical draftsman to draw plans of these things, to be inserted in the specifications, but every up-to-date repair shop should have such a man, or should be able to employ one from the outside for the time needed. For the larger shops a graduate mechanical engineer, with about five years' experience, is almost a necessity; in our budget for next year we have asked for the creating of this position.

The subject of tire equipment is also too broad to permit of full treatment here. Delays, safety and cost are all items which must necessarily be considered. In some departments pneumatic tires are employed and it has been claimed that they are necessary with the high speed at which the apparatus runs. Because of the greater liability of accident when running at high speed, and also because fire apparatus is usually heavy, it appears unwise to exceed a speed of 25 to 30 miles an hour for fire service. A blow-out on a pneumatic tire while responding to an alarm usually means a serious accident. We have obtained excellent results from resilient solid tires; these insure freedom from the troubles of the pneumatic tire and we have experienced no difficulty with the apparatus because of any lack of cushion, although often operating at high speed. A guarantee of 8000 miles, same to be accomplished in three years, is given on tires we buy, this in consideration of the infrequent service of fire apparatus. Under this guarantee and the price at which these tires can be purchased, a low cost for tires a vehicle-mile is assured. Comparatively no trouble has been experienced in obtaining traction with this type of tire or with skidding.

The use of proper sizes to carry the various apparatus is one point which should not be overlooked. Apparatus employing tractors will show a greater percentage of front weight and this, as in the case on our engines, necessitates larger front tire equipment. Our hose wagons are of two types, both propelled through the rear wheels; one with motor under the seat and another type with motor in front of the driver's seat. On the first mentioned type the distribution of weight will approximate 40 per cent. on the front wheels and 60 per cent. on the rear. These cars will average 13,300 pounds, with full equipment. The second type mentioned will weigh approximately 9600 pounds with equipment and has a weight distribution of 20 per cent. on front wheels and 80 per cent. on rear wheels. Although the first of these wagons weighs more than the latter, we are enabled by the difference in weight distribution to employ the same size rear tires (36 by 3.5 dual) on both vehicles, a larger front tire, of course, being necessary on the heavier wagon because of the greater proportion of front weight. From this it will be seen that different makes of apparatus, although used for the same kind of work, vary in total weight as well as in its distribution, and these points should be carefully considered if the best results are to be obtained from the tire equipment.

Fire department service demands exceptional qualities in a tire because of the weights carried and the speed attained, which generates great heat and exerts powerful centrifugal force in the tires. Looking at this subject of tires from its various angles, we are satisfied, from our experience, that the solid rubber tire is generally well adapted for use on fire apparatus.

It might be of interest to the members of the association to discuss somewhat briefly the mechanical needs of a department having motor apparatus. The specifications should provide that a full kit of tools be supplied with each piece, for the purpose of making ordinary repairs and adjustments; also extra spark plugs, a liberal supply of bolts and nuts and an extra supply of valves and valve springs. For six pieces of apparatus of the same type a complete set of extra wheels, fully finished and equipped with tires, and for three, or a less number of such apparatus, one front and one rear wheel should be supplied; in side chain drive apparatus, a supply of extra links should be included.



Mammoth Score Board Across Pier Where the Engine Tests Took Place, the Results Being Posted Each Hour—The Figures Were Later Checked and Revised.

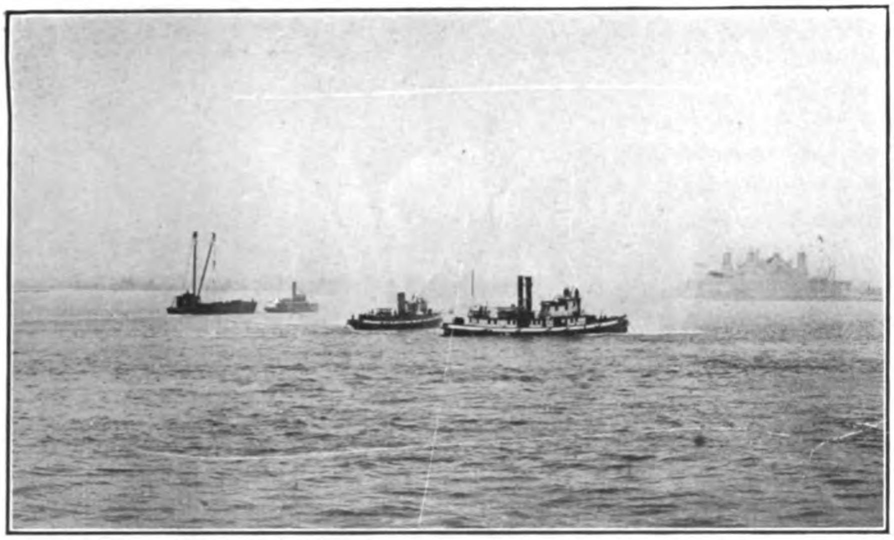
A repair shop in a small department should be equipped with:

One engine lathe, 18-inch swing, 10 feet long.
One drill press, 22-inch table.
One grindstone.
One blacksmith forge.
One portable crane, 2000 pounds capacity, for lifting out the motor, transmission, etc.
One hydraulic hose expander.
One hose testing outfit.
Two or more portable electric drills for holes up to one inch.
A tire repairing outfit.

A large department, in addition to above, should have:

One Monitor lathe, 18-inch swing, six feet long.
One engine lathe, 30-inch swing, 14 feet long.
One engine lathe, 24-inch swing, 12 feet long, with taper attachment.
Five engine lathes, 14-inch swing, 10 feet long, with taper attachment.
One radial drill press, with four-foot arm.
One drill press, 24-inch table.
One drill press, 18-inch table.
One sensitive drill press, 12-inch table.
One planer, eight feet by 26-inch bed.
One shaper, 16-inch stroke.
One Universal milling machine, No. 2.
One Universal milling machine, cutter grinder No. 2.
One power hack saw.
One emery wheel for grinding tools.
A stock of drills, reamers, stocks and dies, including A. L. A. M. standards, emery wheels for roughing down work, a couple of buffing and polishing machines.
A blacksmith shop with a power hammer, capacity of from two to 800 pounds, and a tire heater and shrinking plate.
A nickel plating outfit.
A paint shop.
A brass foundry with one molder (convenient and economical in large cities).
A woodworking shop comprising a wheel machine, band saw, circular saw, planer, variety molding machine, tenoning machine, woodturning lathe, sandpapering machine and a portable drill.

The policy of the association is that the city in which the convention is held shall provide an exhibition hall for the display of apparatus by the manufacturers and whatever equipment and assistance is nec-



Demonstration of the Fleet of Fireboats Off Battery Park, One of the Features of the Entertainment of the Visiting Fire Chiefs.

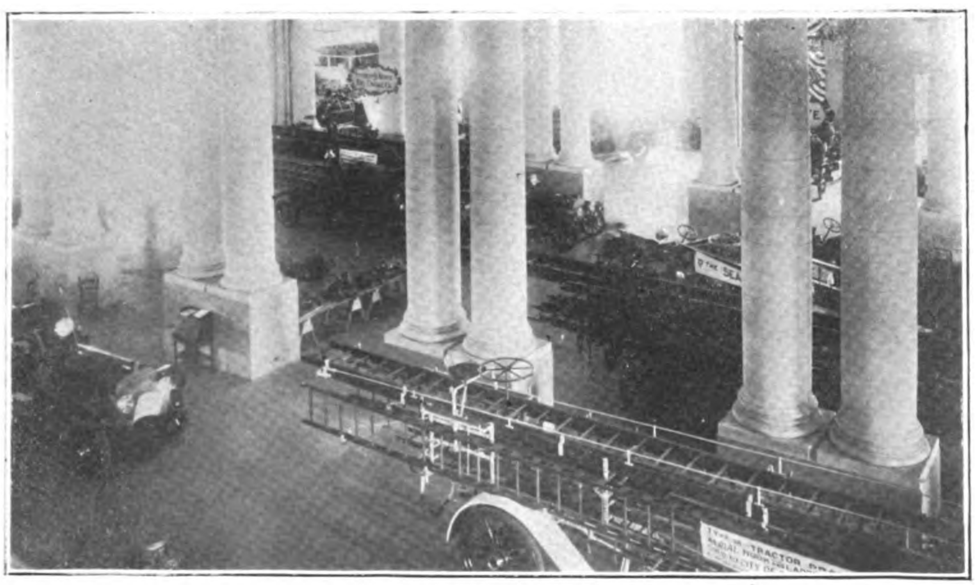
essary for conducting the trials that may be arranged in connection with the convention, and in keeping with this New York engaged Grand Central Palace for the show and for the convention, and secured a pier at the foot of 54th street for the tests of the machines.

Co-operating with the exhibition committee was a committee from the National Board of Fire Underwriters, which consisted of Wilbur A. Mallalieu, chairman; Chief John Kenlon, George W. Booth, Charles S. Demarest and James J. Henry, and the committee on tests of the New York general convention committee. The trials were arranged for with extreme care. Across the head of the pier a great score board was built with a gate in the centre, and on this was posted each hour the result of the work accomplished, but this was unofficial and was merely for the purpose of informing the delegates and others interested of the general working conditions. The committee had the assistance of nearly 100 members of the New York firemen and a sufficient number of police to keep the pier free for the pumping crews and to prevent possibility of interference from the curious.

The purpose was to have the trials equal to all entrants and to afford each the fullest opportunity for demonstrating the capacity of the machines. In connection with the trials the approximate capacities of the engines submitted for trial were determined by preliminary tests, and it was decided that the finals would be according to these conditions: Six hours' run at full capacity, at not less than 120 pounds net pressure, pumping through three streams siamesed into one nozzle; three hours' run at not less than half capacity, at not less than 200 pounds net pressure, pumping through one line of hose and nozzle; three hours' run at not less than 250 pounds net pressure, pumping through one line of hose and nozzle.

The full capacity test was begun at 6:30 in the morning and the trials were continued continuously with such intermissions as were necessary for changing hose, nozzles, etc. During the intermissions the entrants were expected to keep the motor running, and, if practicable, the pumps as well. The conditions to be observed were the following: The engines were each assigned a layout of hose and nozzles such as were found needful during the preliminary trials to insure the maintenance of the required pressure while delivering the rated capacities; the engines drew from the Hudson river with an average lift of 10 feet; but one suction line was permitted for each engine; the engines rated at less than 700 gallons a minute used suctions not more than 4.5 inches inside diameter, the engines rated from 700 to 850 gallons a minute used suctions not more than five inches diameter, and engines rated at 900 gallons a minute used six-inch suctions. Each competitor had the option at the conclusion of the 12 hours' test of continuing an indefinite period with a pressure not less than 120 pounds; not more than two men were allowed as an engine crew, but these men could be changed every three or six hours.

Gasoline of the same grade was supplied to all the machines and there was no specification as to the lubricating oil that should be used. There was no limitation as to the quantity of gasoline or oil used, but it was necessary that the fuel and lubricant consumed be noted. The tests were not open to the public, and only



Portion of the Main Floor of the Grand Central Palace, Where the Apparatus was Shown, as Seen from the Mezzanine Floor.

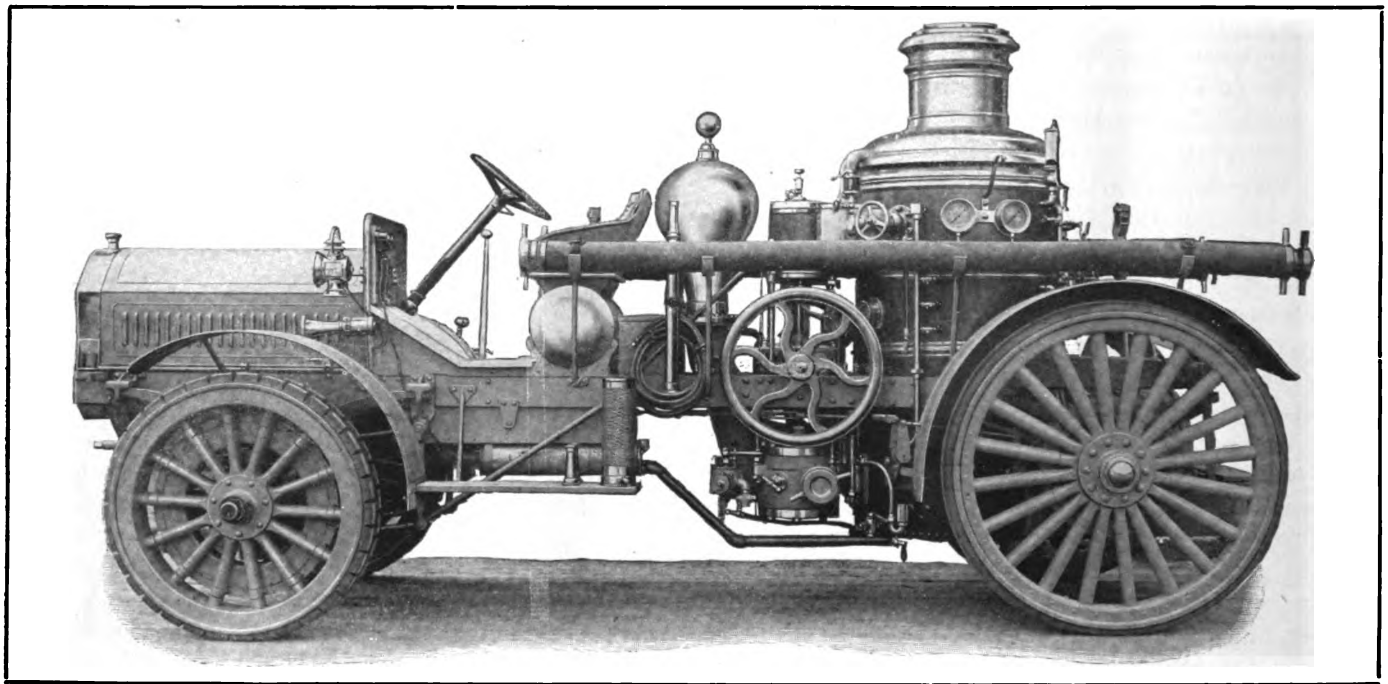
the members of the committee and assistants, engaged in recording results or operating the engines, and the necessary employees of the exhibitors were given access to the pier.

The committee stationed a horse drawn steam fire pump on the dock and at intervals of five minutes a signal for recording nozzle pressure was given by blowing the whistle of the engine, and 30 seconds later a second signal, the readings being made and noted between the blasts of the whistle. This insured uniformity of records for all machines and obviated the possibility of error or confusion incidental to individual time keeping.

Each engine was assigned a station and the machines were located close to the cap logs of the wharf and the nozzles were fixed on the cap logs, with the suction pipes dropped into the water sufficiently deep so that there was a sufficient supply of water no matter what the condition of the tide, and the variance of the water lift is shown by high water at 10:30 in the morning and 4:50 in the afternoon, when the records of maximum and minimum lift were taken, the difference in lift being accounted for by the height of the pumps above the deck of the dock.

Chief John Kenlon of the New York fire department was the executive and under his direction the tests were made without favor and with absolute fairness. He was assisted by Chairman Mallalieu and the compilation of the record was placed in the hands of the National Board of Fire Underwriters. The records were taken for each machine by two men, one reading the nozzle gauge and the other noting the result, and the reading for each machine was given to the chief clerk. The result of each hour's work was computed and posted on the mammoth score board, which extended across the shore end of the pier. The representatives of the manufacturers having charge of the machines were provided with score books in which they could note the work accomplished each hour, for their own or for all the pumps. No person had access to the official figures, and these were later on checked and tabulated with reference to each pump, the revised score being printed and with it the condition of each engine as found by the examining committee, inspection being made of the motors after the trials with reference to the bearings, pistons, cylinders, valves and all working parts.

The work of each engine was carefully noted throughout the test. The time and any conditions that caused loss of pressure, lessening of pumpage, cessation of operation, heating, breakage, loosening of bolts, defective ignition, faulty carburetion, changes from magneto to battery ignition, leaky valves or cylinders, skipping of cylinders, condition of bearings, condition of clutches, repairs of any nature, the cooling of bearings, and any fact that might be regarded as attention and aside from constant operation at the requirements of the test.



American & British Gasoline-Electric Two-Wheeled Tractor Coupled with Steam Fire Pump—One of the New Productions Shown at the Grand Central Palace.

The trials were such as might be expected under stress of a very serious fire, where it would be necessary to work the machines to or very nearly to maximum capacity. There were in all 11 pumps of eight different makes, these being two American-La France engines of 700 and 1400 gallons capacity a minute, two Nott engines of 600 and 800 gallons, two Robinson engines of 750 and 900 gallons, a Seagrave of 1000 gallons, an Ahrens-Fox of 700 gallons, a Luitwieler of 600 gallons, a Knox of 600 gallons and a Waterous of 700 gallons.

As will be noted from the conditions of the competition the machines were worked for six hours at one pressure, for three hours at a second and for three

The Exhibit of the McNutt Non-Explosive Can Company of Patent Containers for Inflammables and Explosive Fluids.

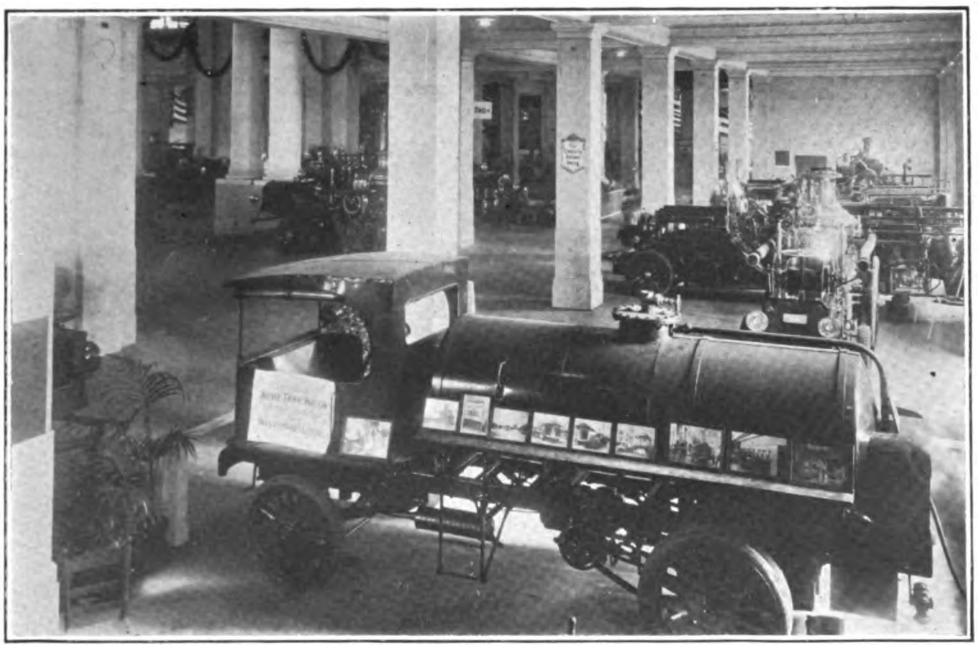
hours at a third pressure, and the official figures show that the Ahrens-Fox and the Waterous pumps were worked the entire 12 hours without any condition arising that was worthy of recording, they having what might be regarded as a perfect score, while the Seagrave pump at the start was 20 minutes getting water because of the necessity of using extra washers to make tight a leaky suction pipe joint. All of the other machines were not in operation the entire periods, as will be shown in the tabulation accompanying the summary.

By reference to the accompanying tabulation it will be seen that the greatest pumpage was by the 1400-gallon American-La France engine, which in 10 hours and 52 minutes discharged 673,416 gallons. The next largest pumpage was by the Seagrave engine, that in 12 hours discharged 542,940 gallons. The third was the Nott 800-gallon engine with 392,716 gallons in 11 hours and 31 minutes, the fourth the Robinson 900-gallon engine with 392,320 gallons in nine hours, the fifth the Robinson 750-gallon engine with 388,615 gallons in 11 hours and 31 minutes, the sixth the Ahrens-Fox 700-gallon engine with 386,520 gallons in 12 hours, the seventh the Waterous 700-gallon engine with 364,440 gallons in 12 hours, the eighth the American-La France 700-gallon engine with 343,695 gallons in 10 hours and 15 minutes, the ninth the Knox 600-gallon engine with 282,818 gallons in 10 hours and 43 minutes, the 10th the Nott 600-gallon engine with 280,135 gallons in eight hours and 55 minutes, and the 11th the Luitwieler 600-gallon engine with 210,408 gallons in seven hours and 44 minutes.

While the total discharge during the period of pumpage can be rated in the order given above it will be understood that this is not the measure that should be made, for the engines were of differing capacities and comparison should be made on the basis of discharge for the actual time of work during each of the three periods, and the average discharge for each hour and for each period contrasted with the rating given by the manufacturer. These figures were not attempted by the committee in charge of the trials, and the original score gave the engine number, the pump pressure, size of nozzle, nozzle pressure, minutes in operation, gallons discharge a minute and each hour. In the compilation in connection with this review these have been grouped to show results for each machine for the entire time of the trials, instead of showing the work of the engines for each hour, which permits easy comparison of the discharge for each hour and the several conditions governing the pumpage.

The tests were conducted under conditions that were ideal in that the weather was clear and the temperature on the pier was high, although somewhat tempered by a light southwest wind, and assumedly the engines were all in condition when they were taken to the pier. Three of the engines were in service 12 hours continuously, the Seagrave 1000-gallon pump, the Ahrens-Fox 700-gallon pump and the Waterous 700-gallon pump.

During the six-hour test the Seagrave pump discharged a maximum of 1060 gallons the second hour and a minimum of 1038 gallons the first hour, and 1049 gallons for the remaining four hours; during the first three-hour period with a rating of 500 gallons the Seagrave pump discharged a minimum of 591 gallons the first hour, 596 the second and 600 gallons the third; during the second three-hour period with a rating of 300 gallons the Seagrave pump discharged 323 gallons the first and second hours and 322 the third. During the six-hour test the Ahrens-Fox pump, with a rating



Section of the Main Floor of the Grand Central Palace, Looking from the Southwest Corner Toward the Main Entrance, Showing Some of the Apparatus Exhibited.

of 700 gallons, discharged a minimum of 706 the first hour, 709 the second, 718 the third, 721 the fourth, 726 the fifth and a maximum of 746 the sixth. During the first three-hour period with a rating of 350 gallons the Ahrens-Fox pump discharged 360 gallons for each hour, and for the second three-hour period with a rating of 330 gallons discharged 343 the first hour, 346 the second and 347 the third. During the six-hour test the Waterous pump, with a rating of 700 gallons, discharged a maximum of 693 gallons the sixth hour and a minimum of 667 gallons the second hour; during the first three-hour period with a rating of 350 gallons the minimum discharge was 352 gallons the first hour and the maximum 359 the third hour; during the second three-hour test with a rating of 300 gallons the maximum was 312 gallons during the first hour and the minimum was 307 gallons the third hour.

The accompanying tabulation gives the detail of the tests for each machine for each successive hour, and the different conditions that developed in connection with the operation of the engines:

No. 1—Seagrave, 1000 Gallons.

Hour	Pump pressure	Size nozzle	Nozzle pressure	Mins. in operation	Gals. a minute	Total discharge
1	123	2.250	47.5	60	1038	62,280
2	126	2.250	49.5	60	1060	63,600

9	175	1.250	45.0	22	310	6,820

Grand total discharge..........................210,408

First hour valve covers on Nos. 3 and 4 cylinders leaky—started at 6:50; engine working on Nos. 2 and 3 cylinders (ignition trouble); shifted to battery and engine worked O. K. Second hour, radiator steaming badly; carburetor out of adjustment and engine irregular in action; this was adjusted and engine worked O. K. Third hour, engine shut down at 8:54—clutch burned out; clutch set up tight and engine started up at 9:20. Eighth hour, bolt dropped out in cross head; shut down 1:47 to 1:57. Ninth hour, withdrew from test at 2:57; hot bearings.

No. 5—American-La France, 1400 Gallons.

Hour	Pump pressure	Size nozzle	Nozzle pressure	Mins. in operation	Gals. a minute	Total discharge

Grand total discharge........................392,716

First hour, valve rocker arm bolts loose on Nos. 5 and 6 cylinders 7:45; engine continued in operation. Second hour, missing on No. 4 cylinder; inlet valve spring broken at 8:00; shut down at 8:16 to replace and started up at 8:45. Third hour, riveted rocker arm pins to prevent loosening, while engine was in operation. Fifth hour, valve rocker arm bolts loose on cylinders Nos. 3 and 4; broke valve rod yoke on No. 3 cylinder at 11:20; this was replaced during first shift of hose at 12:30. Ninth hour, inlet valve springs on Nos. 1 and 2 cylinders broken just before 3:45.

No. 10—Robinson, 900 Gallons.

Grand total discharge........................364,440

First hour, engine varying in speed, missing occasionally; carburetor popping, due probably to air in gasoline line; settled down to good action in about two hours.

The specifications and ratings of the engines, as prepared by the committees, showed the following detail:

No. 1—Seagrave pumping engine, rated at 1000 gallons at 120 pounds pressure, 500 at 200, and 300 at 250. Net weight, without men or hose, 16,370 pounds; tires, solid, five-inch single forward, four-inch dual rear; tread, 68 inches; wheelbase, 14 feet four inches. Engine, own make, six-cylinder, 7.75-inch bore, nine-inch stroke, 144 horsepower. Gear ratio, engine to pump, 1:3.6. Centrifugal pump, three-stage, 11-inch impeller. One gasoline tank, 60 gallons. Height of pump from ground, 43 inches.

No. 2—Ahrens-Fox pump with hose body, rated at 700 gallons at 120 pounds, 350 at 200 and 330 at 250. Net weight, 14,520 pounds; tires, solid, six-inch single forward, four-inch dual rear; tread, 66 inches; wheelbase, 12 feet four inches. Engine, Herschel-Spillman, built to plans of Ahrens-Fox Fire Engine Company, six-cylinder, 5.75-inch bore, 6.5-inch stroke; 79.3 horsepower. Gear ratio, engine to pump, 3.11:1 and 4.33:1. Pump, two-cylinder, double-acting, steamer type; 6.5-inch bore, four-inch stroke. One gasoline tank, 45 gallons. Height of pump above ground, 45 inches.

No. 3—American-La France, triple combination, rated at 700 gallons at 120 pounds, 350 at 200 and 325 at 250. Net weight, 8925 pounds; rear wheels, 5395 pounds; tires, Dayton airless, 4.5-inch single forward, 4.5-inch dual rear; tread, 62 inches; wheelbase, 13 feet two inches. Engine, own make, six-cylinder, 5.5-inch bore, six-inch stroke, 72.6 horsepower. Gear ratio, engine to pump, 1.66:1 and 3:1. Pump, rotary gear; displacement, 1.25 gallons a revolution. Two gasoline tanks, 11 and 28 gallons. Height of suction, 33 inches.

No. 4—Luitwieler, combination pumping engine and hose wagon, rated at 600 gallons at 120 pounds, 300 at 200 and 200 at 250. Net weight, 10,200 pounds; rear wheels, 6200 pounds; tires, solid, four-inch single forward, five-inch single rear; tread, 58 inches; wheelbase, 11 feet seven inches. Engine Trebert, four-cylinder, six-inch bore, 6.5-inch stroke, 57.6 horsepower. Gear ratio, engine to pump, 11.78:1, 24.79:1 and 36.14:1. Pump, three-cylinder, double-acting, six-inch bore, 12-inch stroke, displacement, 8.581 gallons a revolution. One gasoline tank, 30 gallons. Height of suction, 25 inches.

No. 5—American-La France combination pumping engine and hose wagon, rated at 1400 gallons at 120 pounds, 700 at 200 and 640 at 250. Net weight, 12,770 pounds; rear wheels, 6760 pounds; tires, solid, five-inch single forward, five-inch dual rear; tread, 63 inches; wheelbase, 14 feet six inches. Engine, own make, six-cylinder, 7.125-inch bore, eight-inch stroke, 126.2 horsepower. Gear ratio, engine to pump, 2.15:1 and 4:1. Pump, rotary gear; displacement, four gallons a revolution. Two gasoline tanks, 28 and 15 gallons. Height of suction, 36 inches.

No. 6—Knox combination pumping engine and hose wagon, rated at 600 gallons at 140 pounds, 400 at 200 and 325 at 250. Net weight, 14,010 pounds; rear wheels, 7330; tires, solid, five-inch single forward, five-inch dual rear; tread, 70 inches; wheelbase, 14 feet four inches. Engine, own make, six-cylinder, five-inch bore, six-inch stroke, 60 horsepower. Gear ratio, engine to pump, 6.47:1 and 3.77:1. Pump, two-cylinder, double-acting; five-inch bore, eight-inch stroke. One gasoline tank, 30 gallons. Height of suction, 32.5 inches.

No. 7—Nott combination engine and hose wagon, rated at 600 gallons at 120 pounds, 300 at 200 and 250 at 250. Net weight, 12,300 pounds; rear wheels, 6600 pounds; tires, solid, five-inch single forward, six-inch single rear; tread, 71 inches; wheelbase, 11 feet 8.5 inches. Engine, own make, four-cylinder, 6.5-inch bore, eight-inch stroke, 67.6 horsepower. Gear ratio, engine to pump, 1.2:1. Pump, rotary roller, dual or single-acting; displacement, .98 gallon a revolution. One gasoline tank, 40 gallons. Height of suction, 46.5 inches.

No. 8—Robinson, combination pumping engine and hose wagon, rated at 750 gallons at 120 pounds, 400 at 200 and 300 at 250. Net weight, 11,600 pounds; rear wheels, 6160 pounds; tires, solid, five-inch single forward, six-inch single rear; tread, 60.5 inches; wheelbase, 14 feet four inches. Engine, Buffalo Gasoline Motor Company's, six-cylinder, 6.25-inch bore, 6.75-inch stroke, 93.7 horsepower. Gear ratio, engine to pump, 3:1. Pump, three-cylinder, single-acting; six-inch bore, eight-inch stroke; displacement, 2.938 gallons a revolution. One gasoline tank, 30 gallons. Height of suction, 39.5 inches.

No. 9—Nott combination pumping engine and hose wagon, rated at 800 gallons at 120 pounds, 400 at 200 and 360 at 250. Net weight, 14,360 pounds; rear wheels, 8150 pounds; tires, solid, six-inch single forward, five-inch dual rear; tread, 71 inches; wheelbase, 11 feet 8.5 inches. Engine, own make, six-cylinder, 6.5-inch bore, eight-inch stroke, 101.4 horsepower. Gear ratio, engine to pump, 1.3:1. Pump, rotary roller, dual or single-acting; displacement, 2.63 gallons a revolution. One gasoline tank, 40 gallons. Height of suction, 46.5 inches.

No. 10—Robinson combination pumping engine and hose wagon, rated at 900 gallnos at 120 pounds, 500 at 200 and 350 at 250. Net weight, 11,150 pounds; rear wheels, 5890 pounds; tires, solid, five-inch single forward, six-inch single rear; tread, 60 inches; wheelbase, 14 feet five inches. Engine, Buffalo Gasoline Motor Company's, six-cylinder, 6.25-inch bore, 6.75-inch stroke, 93.7 horsepower. Gear ratio, engine to pump, 2.5:1 and 3.75:1. Pump, three-cylinder, single-acting, six-inch bore, eight-inch stroke; displacement, 2.938 gallons a revolution. One gasoline tank, 30 gallons. Height of suction, 37.75 inches.

No. 11—Waterous combination pumping engine and hose wagon, rated at 900 gallons at 120 pounds, 500 at 200 and 350 at 250. Net weight, 13,830 pounds; rear wheels, 9060 pounds; tires, solid, five-inch single forward, four-inch dual rear; tread, 69 inches; wheelbase, 11 feet four inches. Engine, own make, six-cylinder, 6.5-inch bore, seven-inch stroke, 101.4 horsepower. Gear ratio, engine to pump, 2.23:1. Pump, four-cylinder, single-acting, 4.75-inch bore, eight-inch stroke; displacement, 2.455 gallons a revolution. Two gasoline tanks, 20 gallons. Height of suction, 23.25 inches.

The examination of the machines at the conclusion of the test showed that all the bearings, pistons, cylinders, valves, etc., were in good condition except the following: No. 4, no inspection, as machine was withdrawn from the test; 7, gasket leaks on No. 2 cylinder, nut gone from one valve rocker arm bolt; 8, Nos. 2 and 3 connecting rods each had loose check nuts on cap bolts, could not come off on account of cotter pins ("holding" nuts tight); 9, one valve rocker arm bolt broken, three valve rocker arm bolts loose, nuts and washers missing, two inlet valve

springs broken; 10, leak from water jacket into No. 6 cylinder, allowing water to enter cylinder and crankcase; three valve springs broken.

The following tabulation shows the total time each machine was in service, the maximum and minimum suction lift and the amount of gasoline used:

	Time		Max. Lift		Min. Lift		Fuel
No.	Hrs.	Mins.	Ft.	In.	Ft.	In.	Gals.
1	12	0	14	1	8	7	219
2	12	0	14	3	8	9	117
3	10	15	13	3	7	9	108
4	7	34	12	7	7	1	56.75
5	10	52	13	6	8	0	255

9	11	31	14	4	8	10	159
10	9	0	13	8	8	2	100
11	12	0	12	6	7	0	148

It is expected that the work of the machines will be carefully analyzed by the engineers of the National Board of Fire Underwriters, and the information will be placed at the disposal of the different insurance companies.

The exhibition of fire department apparatus consisted of displays of about 50 different pieces of equipment, some of which were shown in the main floor of the Grand Central Palace and some in the streets, while some of the exhibits were seen both in the building and in different parts of the city. There were in all 14 exhibitors, these including the Ahrens-Fox Fire Engine Company, Cincinnati, O.; American & British Manufacturing Company, Providence, R. I.; American-La France Fire Engine Company, Elmira, N. Y.; James Boyd & Bro., Inc., Philadelphia, Penn.; Front Drive Motor Company, Hoboken, N. J.; International Motors Company, New York City; Knox Automobile Company, Springfield, Mass.; Luitwieler Pumping Engine Company, Rochester, N. Y.; Martin Carriage Works, York, Penn.; Nott Fire Engine Company, Minneapolis, Minn.; Pope Manufacturing Company, Hartford, Conn.; Robinson Fire Apparatus Manufacturing Company, St. Louis, Mo.; Seagrave Company, Columbus, O.; Waterous Engine Works Company, Minneapolis, Minn.

The exhibits were as follows:

Ahrens-Fox Fire Engine Company, model A pump and hose carrier, six-cylinder, 80 horsepower motor, two-cylinder double-acting piston pump, with hose capacity of 1200-1500 feet; model D combination hose and chemical wagon with auxiliary or "booster" pump.

American & British Manufacturing Company, two gasoline-electric two-wheel tractors (Hoadley system) attached to steam pumps of the improved Amoskeag type.

American-La France Fire Engine Company, 65-foot aerial ladder truck, two 75-foot aerial ladder trucks; type 10 combination hose and chemical wagon; type 12 combination fire pump, chemical and hose wagon; type 14 city service ladder truck and chemical engine, two chemical and hose wagons; type 15 fire pump, one six-cylinder 100 horsepower tractor and steam fire pump; type 12 triple combination fire pump, chemical and hose wagon, with six-cylinder, 70 horsepower motor; type 15 combination fire pump and hose wagon with six-cylinder, 126 horsepower motor; steam chemical and hose wagon built in 1902 for the New London, Conn., fire department.

James Boyd & Bro., combination hose and chemical wagon on a White chassis; Boyd four-cylinder, 60 horsepower combination hose and chemical wagon on a Boyd chassis, and display of parts of which the Boyd machines are constructed.

Front Drive Motor Company, Christie front-wheel driven tractor and steam fire pump.

International Motor Company, Mack tractor attached to hand ladder truck, hose wagon with turret nozzle, hose wagon, combination hose and chemical wagon.

Knox Automobile Company, three Knox combination fire pumps and hose wagons, Knox triple combination fire pump, hose and chemical wagon; Knox piston fire pump, Martin tractor, Martin tractor coupled to a steam fire pump loaned by the Springfield, Mass., fire department, Martin tractor coupled to steam fire pump and a Martin tractor coupled to a 75-foot aerial ladder, the last two being demonstrated in the streets.

Luitwieler Pumping Engine Company, combination fire pump and hose wagon with 57 horsepower, four-cylinder motor.

Martin Carriage Works, combination chemical and hose wagon.

Nott Fire Engine Company, two four-cylinder, 67 horsepower motor fire pumps, one six-cylinder, 101 horsepower motor fire pump.

Pope Manufacturing Company, one shaft-driven combination hose and chemical wagon, one chain driven combination hose and chemical wagon.

Robinson Fire Apparatus Manufacturing Company, combination fire pump and hose wagon with six-cylinder, 93 horsepower motor, having capacity of 750 gallons a minute; combination fire pump and hose wagon with six-cylinder, 93 horsepower motor, having capacity of 900 gallons a minute.

Seagrave Company, 75-foot aerial ladder truck with six-cylinder, 80 horsepower motor tractor, combination hose and chemical wagon with four-cylinder, 53 horsepower motor, 1000-gallon centrifugal fire pump with 144 horsepower, six-cylinder motor, combination city service apparatus with six-cylinder, 80 horsepower motor.

Waterous Engine Works Company, combination fire pump and hose wagon with six-cylinder, 101 horsepower motor.

Turning to these exhibits it may be stated that there were a number that were shown for the first time, though the general policy of the manufacturers of fire apparatus is to begin the marketing of a production immediately upon its completion. The exhibition was the largest ever seen in the world, and the machines represented the greatest advance ever made in the building of fire protective equipment.

The earliest gasoline motor propelled apparatus was the converted pleasure car chassis, or chassis for such cars, adapted to such requirements as could be anticipated without knowledge from experience. These were utilized for quick work, the transportation of departmental officers, for chemical engine and for hose wagons, and then came the endeavor to construct fire pumps that could be driven by the vehicle motors. Most of the fire pumps have been developed along the lines of automobiles, just as freight motor wagons have been developed from pleasure vehicle construction, but with the realization that many of the towns and cities have thoroughly dependable steam fire pumps and horse drawn ladder trucks and from economical reasons do not desire to sacrifice these, although wanting the greater speed possible with the motor apparatus, some of the manufacturers have turned to the building of tractors with which the steam pumps and horse trucks may be converted so as to have the utility and the practicality of equipment motor propelled.

In this connection it may be well to point out that the American & British Manufacturing Company, the American-La France Fire Engine Company, Front Drive Motor Company, Knox Automobile Company, International Motor Company and the Seagrave Company have developed tractors, which were exhibited, and of these the American & British and the Front Drive Motor machines are front wheel driven, and the others are the four-wheel type, these being driven by the rear wheels as in conventional motor vehicle practise.

There is no doubt whatever that tractors have attracted a great deal of attention from fire department engineers and municipal officials, and this from the fact

that not only are they economical through the conversion of horse apparatus, but also through the possibility of having the thoroughly dependable steam pumps, which are regarded by many as being at least the equal of any of the gasoline motor pumps. Whatever the relative qualities and merits of the two forms of pumps may be there is no doubt that the judgment of those purchasing must determine that which appears best suited for the needs, and while there are many who believe that the gasoline motor pump is still experimental, this being particularly of large cities, the practicability of the tractor and the steam pump is unquestioned.

The disposition of many leading fire engineers is to make experiment with both tractors and motor fire pumps, but to make no sweeping changes until continued experiment has proven the reliability of the gasoline pumping engine from the viewpoint of those considering its use. This condition has brought a number of fire apparatus manufacturers to the production of tractors, and of the 14 exhibitors six of them build them commercially. Two of these, the A-B (American & British) and the Christie, are the two-wheel type and when attached make the conventional four-wheel equipment. The American-La France, Martin, Mack and Seagrave are the self-supported type and these, save the Martin, which has one forward wheel, when used make the apparatus six-wheeled, and consequently longer than either the A-B or the Christie.

One of the claims made for the four-wheeled apparatus using the non-self-supporting tractor is the greater ease of handling in narrow streets and congested traffic, because of the well known possibilities with vehicles of short wheelbase, as well as the faster time that can be made in traffic where turns are frequent. But some of the makers of the four-wheel tractors maintain that with them 75-foot ladders may be turned in 30-foot streets; that they meet with practically all of the requirements for fire department purposes. Whether or not the desired qualities may be realized is for the chiefs of the fire departments to decide—the purpose of this review is to establish the fact that the fire apparatus manufacturers have realized the need of tractors for the heavy equipment and have sought to supply the demand. Of these the Martin has been built for several years and there are now about 150 machines of this kind in use, it having been standardized, and having been worked out in many freight installations as well as in fire department equipment. It is the oldest and best known of the tractors seen at the exhibition.

The Christie tractor has been built for about two years, the first being placed in the service of the New York City department, Dec. 1, 1911, and since that time something more than 100 have been built. The first Christie tractors were constructed with a turntable so that after the wheels had been turned 30 degrees by a movement of the gear changing lever the driving movement of the engine was changed from the front wheels to the turntable, so that the wheels could be turned to an angle of 90 degrees, by moving the turntable 60 degrees. Having reached this point the changing of the lever would cause the power to be applied to the front wheels and the machine could be driven forward. The turntable and the attendant complications have been eliminated and the wheels are now turned in the same radius as in any standard automobile design. Aside from this the tractor has been continued unchanged. The motor is placed transversely in the chassis and the drive is from a gearset affording high and low speeds and reverse through a chain to a counter or cross shaft having universal joints at the ends, and attached to the ends of the shafts are spur pinions that mesh with large internal gears mounted on the wheels. The universal joints in the cross shaft are directly above the steering pivots of the axle.

The American & British, known as the Hoadley system, shown for the first time, was the gasoline-electric, although the same method of driving may be utilized with a standard electric battery that may be charged as frequently as desired. This tractor consits of a short chassis that is mounted on two wheels, that carries the power plant and driving mechanism, and to the rear of this the engine, truck or cart may be attached. The chassis frame carries the four-cylinder, water-cooled, British-American motor, to which is directly coupled the generator. The capacity of the generator is dependent on engine speed and it may be varied to meet any requirement. The chassis is carried on two semi-elliptic springs and these are mounted on a truss axle, the upper and lower members being held by two cross members bolted to them.

Pivoted between the ends of the upper and lower axle members are mounted two 4.5-horsepower General Electric motors, enclosed in steel frames or shells. These are carried on Timken roller bearings. The armature shaft of the motor extends at either end and carries a bevel gear. These bevel gears mesh with two other bevel gears on cross shafts mounted in the extensions of the motor housing, and on the ends of these cross shafts are spur pinions that mesh with a large internal gear attached to the wheels. The cross shaft gears are mounted, the one at the inside and the other at the outside end of the cross shaft so that the spur pinions are driven in the same direction.

The outside of the motor frame carries the wheel spindle and on this the wheel is mounted. The wheel and the motor turn on the pivot between the axle members and are actuated by a conventional steering linkage and hand wheel. The motor frame is sectional, so that the ends may be removed to afford access to the bevel gears and cross shafts, or to reach the armature bearings and the motor brushes. The internal gear of the wheel is protected by a telescoping housing, so that all the moving parts are shielded from water, dust, etc. The wheels are of large size and the tires are a band type. The motor has the usual equipment and auxiliaries of the gasoline installation, with a sufficient radiating system to insure against heating when

driven for a long time continuously. The first machines were produced for use with steam fire pumps carried on large wheels with a brake of the locomotive type on the rear wheels, but those now building are fitted with a service brake on the driving wheels and an emergency brake of the locomotive type on the rear wheels. The gradation of the power as applied for driving purposes is through the engine variations, but there is also a three point controller that affords two forward speeds and reverse, and there is the possibility of the use of these with the variance of the engine, so there is a very wide difference of speed of the tractor.

The American-La France, Mack and Seagrave tractors are conventional four-wheel types, driven by gasoline motors. The American-La France tractor is designed so that horse apparatus may be converted without withdrawal from service, and it is propelled by a six-cylinder, water-cooled motor of 100 horsepower, the drive being by shaft, jackshaft and side chains to the rear wheels. The rear end of the chassis carries a circular frame on which the "fifth wheel" of the truck is installed and secured, this permitting the tractor to be swung in either direction 90 degrees. The wheelbase is 156.75 inches. The Mack tractor is practically the same in general design, but the turntable at the rear is a large ring into which a cup-shaped ring is fitted, and the latter carries the forward end of the ladder truck or steam pump frame. Should there be inequality of road surface the cup-shaped ring will move in its support without causing a strain upon the chassis or the frame it carries, there being much the same action as might be expected from a universal joint. This movement of either part of the equipment is allowed independently and a variation of 15 degrees in each can be compensated.

The Seagrave tractor is built with either a four or six-cylinder motor and it also carries at the rear of the chassis a turntable which has a rocker plate to compensate for inequalities in the road surface. It is maintained for this that it is practical to convert these machines into combination hose and chemical wagons by the removal of the turntable and the installation of a body and chemical tank. The motors are either 50 or 80 horsepower.

The American-La France is building a two-wheel tractor that can be used for the same purposes as the American-British or the Christie, but this is gasoline motor driven and the special characteristic of this is a truss front axle with a series of cross members. Mounted at either end of the axle is a short shaft. Near the inner end of the shaft is a sprocket. The outer end of the shaft carries a bevel gear. Pivoted between the ends of the upper and lower axle members on Timken bearings is a heavy bronze housing, square in form and approximately eight inches depth. This housing will swing 39 degrees. Mounted between the ends of the axle members, within the housing is a vertical shaft, on which are carried at either end a bevel pinion. The upper pinion meshes with the bevel gear on the outer end of the horizontal shaft in the axle, and the lower pinion meshes with a bevel gear on the end of the axle spindle carried in the square housing.

The two axle shafts are driven by chains and these turn the vertical shafts and the axle spindle through the two pinions on the vertical shaft in the square housing, and this action is continued with no greater loss of power, no matter what the angle of the wheel. This is an adaptation of the drive used in the Krieger electric carriages in France, and which has been adopted by the Panhard-Levassor heavy vehicles in France. In the American-La France tractor, however, the vertical shaft and the bevel gears and pinions are enclosed in a telescoping housing that is grease and water tight, and which protects it against wear and abrasion. The first of these tractors and the axle construction were shown in connection with the exhibition of this company, but there was no demonstration. The tractor is built with a view to utilizing it for the conversion of horse steam fire pumps and trucks.

A decided novelty in a fire pump was shown by the Luitwieler Pumping Engine Company, in which automobile practise is departed from and an endeavor sought to construct what will afford the greatest capacity and eliminate what are considered by the designer as inherent faults in automobile construction. This is a combination engine and hose carrier and is the first machine produced. It is the intention of the company to build these in 600 and 750-gallon capacities and to build pumping engines with capacities of 850 and 1000 gallons, as well as smaller combination hose and chemical wagons and fire pumps of 250 gallons capacity, both with and without hose.

In this machine the motor is installed directly above the rear axle and the radiator is behind the motor to protect it. The engine cranks from the rear and the cone clutch is between the engine and the jackshaft. The ends of the jackshaft are above the chassis frame and the transmission gearset is in combination with the jackshaft, but is transverse in the frame. The gearset is a sliding type, affording three ratios of speed. The jackshaft consists of a shaft on which is a sleeve, and this sleeve carries the gears of the gearset. The shaft has at its outer ends the driving sprockets, from which chains extend to the rear wheels.

Forward of the jackshaft is installed the cam-actuated, three-cylinder piston pump, and this is driven by a chain from the jackshaft. The gearset may be used to give three speed ratios for driving the machine or for operating the pump, there being two clutches so that for driving the jackshaft and sleeve are coupled, but for pumping the driving is through the sleeve alone, and the change can be made by moving a lever that is independent of the customary gear changing system. The possibilities with the change of speeds for pumpage is seen when it is understood that the high ratio gives full pump capacity at 120 pounds pressure, the intermediate 240 pounds at half capacity, and 400 pounds at quarter capacity, this making it possible to force streams through long lines of hose.

The machine is driven by a Trebert motor having 57.6 horsepower, a 2.5-inch crankshaft, with five main bearings having a total length of 20.75 inches. The bore is six inches and the stroke 6.5 inches. All working parts of the motor are enclosed. The weight of the engine is 10,200 pounds and it is claimed that the weight is evenly distributed on all four wheels, this lessening the skidding and equalizing the stresses upon the machine, and permitting the use of four-inch tires forward and five-inch tires at the rear. The wheelbase is 139 inches, and with the engine carried over a platform spring and the elimination of the throw of the water pump the strains upon the construction are minimized. The seat for the driver is upon the top of the water pump cylinders. The control is conventional and the searchlight is constructed to turn with the wheels, this always lighting the street or road ahead of the engine. Under the chassis is a supplementary or auxiliary radiator that may be used in the event of long runs. Above the engine and pump mechanism is a hose bed or tray 10 feet long, and by the use of curtains the entire machinery may be enclosed in cold weather. There are many ingenious devices incorporated in the apparatus, such as for priming the cylinder from the main fuel tank, for cooling the cylinders by a direct supply of water from the pump, for cutting out the radiator and cooling from the pump when necessary, of cooling the exhaust pipe by water, for utilizing the auxiliary radiator, and for pivoting the cross spring of the rear platform to minimize chassis strains from road inequalities. The main radiator is a sectional type from which a section may be taken at will and the use of the cooler continued. The engine is open in the chassis and is not covered, so that every part is accessible and is under the eye of the operator. One very interesting device is that by which the pump pressure may be varied instantly, this being done by a hand lever that affords seven changes.

One of the features of the Ahrens-Fox "Scout," a combination chemical-hose wagon, is an auxiliary pump of 50 gallons a minute capacity that is carried forward of the radiator and driven from an extension of the engine shaft. To this pump a line of hose may be coupled and the water may be pumped from this through the hose used for discharging the chemical solution in the tank. The machine can be connected with a hydrant and should the chemical in the tank be sufficient more water need not be used, but should this be exhausted the pump will force water through the chemical hose from the hydrant, and by use of a patent nozzle two sizes of stream can be used. The hose is carried on a reel beneath the seat and is concealed, but it is always connected and it can be drawn out or reeled and utilized instantly, the water or chemical flowing through the hose whenever desired by the firemen. In the event of no hydrant supply of water the tank can be filled by buckets and the water drawn from that by the pump.

The Waterous Engine Works Company showed a combination pump and hose wagon of conventional design, having a six-cylinder motor of 101 horsepower, fitted with a four-cylinder, single-acting pump, having a capacity of 700 gallons at 120 pounds pressure.

The Nott Fire Engine Company exhibited three machines, two of the combination engine and hose wagon type with four-cylinder motor having 67.6 horsepower equipped with a rotary roller pump, either dual or single-acting, and one with a six-cylinder motor having 101 horsepower and fitted with a similar pump. One of the four-cylinder pumps had been driven upwards of 2000 miles, making demonstrations in different cities from the Middle West to New England.

The Boyd machines were of conventional type, as were the Pope-Hartford combination wagons, while the Knox engines were the standard productions of the Knox Automobile Company. The Martin Carriage Works combination hose and chemical wagon was an excellent machine and was admirably equipped. The hose wagons built by the International Motor Company were standard types.

All of the machines shown were of excellent design and were generally approved by the firemen, and of these it was noticeable that only the Boyd productions were fitted with electric engine starters. There has been no apparent inclination of apparatus builders to install engine starters, there being an apparent belief that these are not necessary where the machines are kept in quarters and protected, while many maintain that starters add to the complications and require additional care, to say nothing of the possibility of being affected by the water during a fire.

The desirability of electric lighting is questionable in the minds of many of the fire chiefs in view of the additional equipment and the possibility of failure because of the condition under which such apparatus is used. The standard equipment for machine is gas lamps, the fuel being supplied from tanks.

In the accessory division of the exhibition the majority of the manufacturers of rubber products, even the tire makers, showed fire hose, and there was but little attention given to displays of tires. The New Departure Manufacturing Company, Bristol, Conn., had an exhibit of electric and hand operated bell equipment for fire apparatus that attracted much attention. The McNutt Non-Explosive Company exhibited a great variety of containers for storing gasoline and other fluid of an inflammable character. The Martini & Huneke Company of America displayed a new type of gasoline storage apparatus suited for garage purposes, which may be adapted to tank wagons and the same protection given to the delivery of fuel as is afforded by the stationary installations. There was also a display of gasoline storage equipment made by S. F. Bowser & Co., Inc. The Pyrene Company of America showed its well known line of fire extinguishers for vehicle and general purposes, and very large exhibits were made by the Timken Roller Bearing Company and the Timken-Detroit Axle Company, these including roller bearings and different forms of axles suited

for fire apparatus construction. The Sheldon Axle Company's display was of front and rear axles, transmission gearsets, worm driven rear axles, wood and steel wheels, springs and other parts produced by this concern. Some of these productions, especially the worm driven axles, are new and were seen for the first time. The spring display was of all forms adaptable for fire department service. The Sewell Wheel Company, Detroit, Mich., exhibited and demonstrated its well known types of cushion wheels for light and heavy vehicles. The remainder of the exhibition was made up of fire protective and life saving equipment, ladders, fire extinguishers, and the like. These exhibits came in for much attention.

The firemen at the closing session of the convention elected the following officers: President, Thomas Hanley, Jacksonville, Fla.; first vice president, Hugo Leiphs, Lansing, Mich.; second vice president, Harry Marston, Brockton, Mass.; secretary, James McFall, Roanoke, Va.; treasurer, George Knofflock, Mansfield, O. The next session of the association will be held at New Orleans, La.

At Philadelphia, Penn., the Diamond-Keystone Supply & Transportation Company has been organized for the purpose of transporting produce from farms within a reasonable distance of Philadelphia to that city, and hauling supplies of all kinds from Philadelphia to the farmers. Much of this work is now done by the railroads and it is believed that the haulage can be profitably done with machines at prices less than are now paid, and by prompt and regular daily deliveries better serve the market.

The Toledo Carriage Woodwork Company, Toledo, O., has begun the manufacture of a 1500-pound delivery wagon which will be marketed under the name of Trojan. The machine has a unit power plant installed beneath the floor and the drive is by bevel gear through a floating rear axle.

FORD BUYS KELLY TRUCKS.

Four Three-Ton Machines Now in Use at the Big Manufactory at Detroit.

The Kelly-Springfield Motor Truck Company, Springfield, O., has just delivered to the Ford Motor Company at Detroit, Mich., two three-ton Kelly trucks, which will be used in the haulage of materials and supplies in and about Detroit. The plant of the Ford Motor Company is one of the largest in the industry and it is credited with a capacity and facilities for producing more than 1000 Ford pleasure cars daily under favorable conditions for operation, but this is not the average daily output. In fact, so far as known, there has been no definite statement made by the company as to the number built, either maximum, minimum or average.

The Ford chassis, when fitted with bodies, may be serviceable for some forms of haulage, but they have not sufficient capacity to make them preferable to machines of greater size, and to utilize them would necessitate the employment of a driver at least for each. In other words, when considering the uses, it would require five Ford chassis and five drivers to do the work done by one driver and a 3000-pound truck. Thus the saving in drivers' wages is an item of large importance, and were all else equal the truck would be preferable. The company first purchased two Kelly trucks and after using them in all kinds of haulage it added two more. The accompanying illustration shows some of the machines in the factory work.

Two of the Four Kelly Three-Ton Trucks Utilized in General Haulage at the Plant of the Ford Motor Company, Detroit, Mich.

The Ingalls Lumber Company, New Haven, Conn., has a four-ton Kissel truck in service that is, according to L. S. Ingalls of the company, doing the work for which 17 horses were formerly used. The truck is driven three round trips a day, covering 20 miles a trip, carrying 60 railroad ties, and a four-horse truck can make but one trip, carrying 50 ties, and can work but five days a week.

The Tiffany Electric Company, which was recently organized at Pontiac, Mich., by E. L. Pelletier and others, to build electric vehicles, will begin the manufacture of a 1000-pound delivery wagon about Oct. 15.

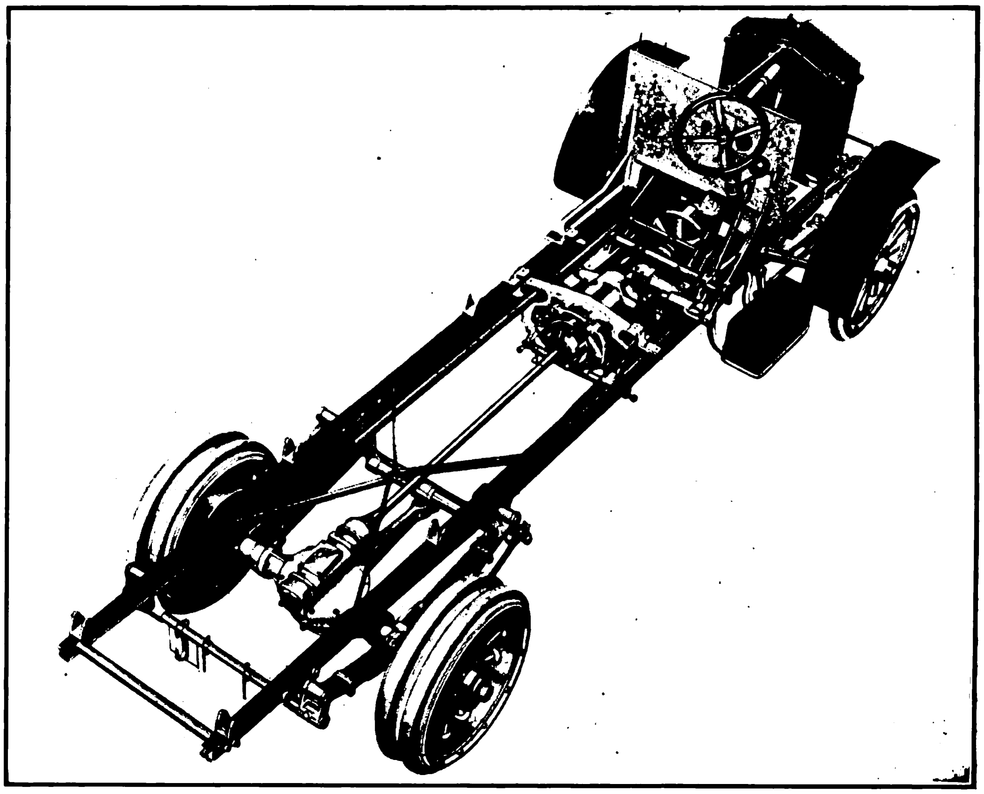
The recently organized Johnstown, Penn., Motor Car Company has plans to erect a factory for the building of a motor wagon from plans developed by R. R. Herchelroth from patents held by him.

PIERCE-ARROW TWO-TON TRUCK.

THE Pierce-Arrow Motor Car Company, Buffalo, N. Y., has begun the commercial production of a chassis having a capacity of 4000 pounds, and is now in readiness to deliver these machines. Like the five-ton truck that has been built for upwards of three years the new machine is worm driven, and it is intended to meet the requirements of those who desire a lighter, dependable vehicle of comparatively fast speed and suited for many classes of work.

In keeping with the policy of the company to build machines that can be regarded as standardized in the broadest sense of the word, and which will serve the purpose of owners in all reasonable working conditions, the design was carefully worked out. Generally it may be stated that the light chassis is a reproduction of the larger, which has been established by experience as being satisfactory and reliable, but in this the company has incorporated such minor improvements and refinements as the experience of three years has established as desirable or necessary. No radical changes were made in the design, and no departure has been made from the methods of manufacturing.

The 4000-pound machine represents all that the engineering force of the company has found practical or useful. It was developed with the purpose of producing a type that could be continued for a long period without change, having the qualities of simplicity and accessibility, with ample margins of safety.

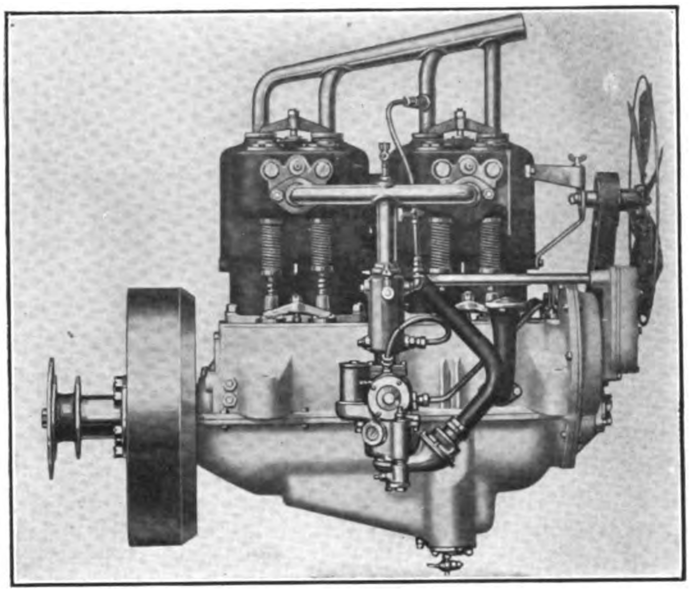


The Chassis of the New Pierce-Arrow Two-Ton Worm Driven Truck.

The motor is practically a smaller type of that used in the five-ton truck. It is a four-cylinder, water-cooled, four-stroke cycle, T head construction with bore of four inches and stroke of 5.5 inches, that is rated by the S. A. E. formulae at 25.6 horsepower, but it will develop 30 horsepower at 1000 revolutions, and it is governed automatically to 1050 revolutions a minute, at which speed, with standard gear reduction, it will drive the chassis at 16 miles an hour. The cylinders are cast in pairs and these, the pistons, the crankshaft, camshafts, connecting rods, valves, valve operating mechanism, timing gears and the fittings are designed and manufactured exactly as are those used in the engine of the five-ton truck.

The lubrication of the motor, which is extremely important, is primarily by a large rotary pump actuated from a camshaft that takes the oil from a well in the base of the crankcase chamber and delivers it under pressure to a large tube extending the length of the crankcase. From this tube passages extend to the main bearings and thence through channels drilled in the crankshaft to the connecting rod big end bearings. From these bearings the oil in excess of the quantity required for lubrication is forced out by the pressure and is distributed in the form of spray by the centrifugal movement of the crankshaft over the interior of the engine, lubricating the camshaft and wristpin bearings, the cylinder and piston walls, the valve tappets and guides. The drainage is collected in the base of the crankcase and is drawn through a filter into the oil well, being used constantly. Practically all of the oiling system is inside the engine case, so that should there be a slight leak the oil drains to the oil well and there is no loss of lubricant. There are two outside tubes, the one leading to the pressure gauge and the relief valve on the dash, and the other the return lead to the crankcase. But four joints are outside the motor case. The height of the oil is indicated by a float gauge.

The motor is cooled by a circulation of water through the spaces in the cylinder jackets by a centrifugal pump coupled directly with the timing gears, and the water is cooled by a vertical tube radiator. The ignition system consists of a Bosch independent magneto, and extreme care has been taken to insure its reliability under all conditions of operation. The system is controlled by a switch on the dash directly connected with the magneto. The high-tension wiring is



The Intake Side of the Pierce-Arrow Two-Ton Truck Motor.

strung through fibre blocks and through the air, insuring maximum insulation. The spark plugs are installed in special sockets above the pistons, and are located where a steady and uniform spark will be produced.

The carburetion is by a standard Pierce-Arrow carburetor, modified to meet the special requirements of the motor. It is an automatic type, easily adjusted and controlled and that it is reliable has been established by long experience. Throttle control is by a foot accelerator.

The clutch is a standard leather faced cone type, with surfaces of large area, and it is operated by a pedal that actuates a fork fitted with two ball bearings, these bearings contacting with the clutch flange and insuring ease of movement and minimizing wear. The mechanism is simple and decidedly effective.

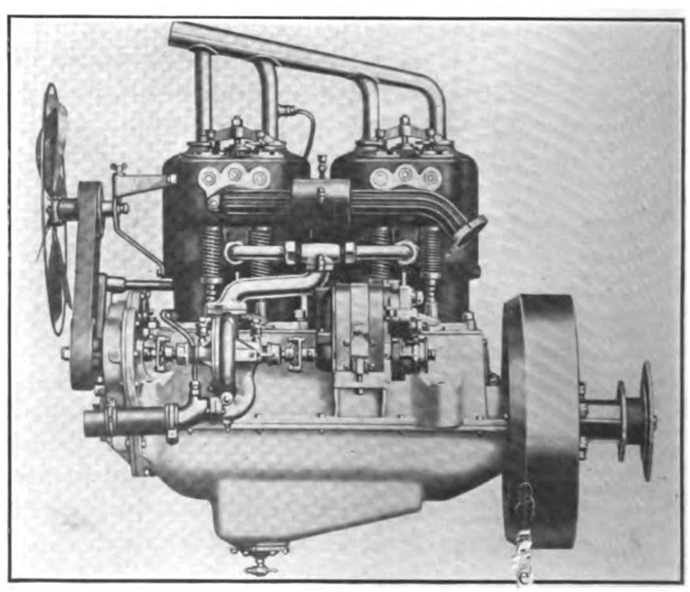
Between the clutch and the transmission gearset is a double universal joint that will compensate for any variance in alignment. The joint is an internal and external gear type, having large bearing surface, and it is so formed that the grease with which it is packed will reach and constantly lubricate the gears. The joint is fully enclosed and is dust and water tight.

The gearset is a three-speed ratio sliding gear type with reverse, and is so designed that a safety clutch prevents more than one gear being in mesh at a time. The gears and shafts are made of high grade steel, carefully heated treated and designed for the stresses they must endure. The gear faces are wide and the shafts are mounted on self-aligning ball bearings, even at the spigot end of the main shaft. The case is made practically oil tight and there is but little probability of loss of lubricant. The gearset speed ratios permit maximums of 16 miles an hour on direct drive, eight miles on intermediate, four miles on low and 3.33 miles in reverse. The gearset is operated by a side lever. The drive is from the gearset by shaft with a universal joint at either end and worm to a gear wheel with which is incorporated a spur gear differential. The rear axle is enclosed in a steel housing and it is a full floating type, the axle shell carrying the full weight of the chassis and load and the axle shafts driving the machine.

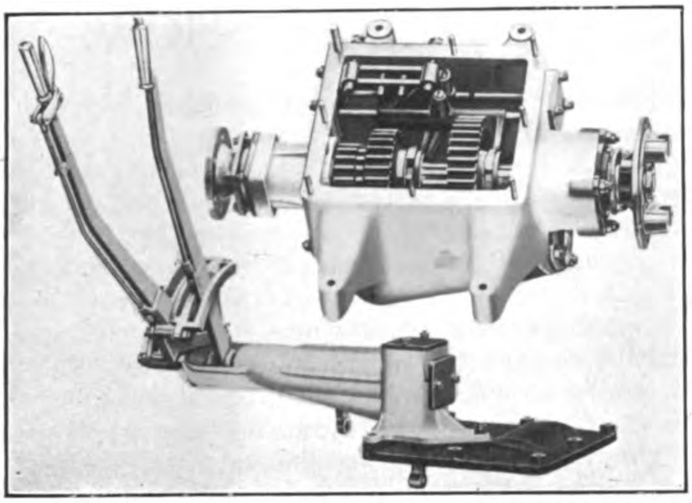
The chassis frame is a channel section pressed from special steel and heat treated. It is 34 inches width. This is mounted on extra long semi-elliptic springs and the forward axle is a special steel forging. The overall length of the chassis is 18 feet six inches, and the width is 66 inches. The wheelbase is 150 inches. The steering gear is a nut and worm type, such as has been used in the larger truck with much success. The relation of the rear axle is maintained by radius rods and a sturdy torque arm from the centre of the rear axle housing to a frame cross member. The driving effort is through the radius rods and there are no driving stresses upon the rear springs. The wheels are of wood, fitted with 36 by four-inch tires, single in front and dual at the rear. The brakes are ample, the contracting band service brake operating on a drum on the driving shaft at the rear of the gearset, and the emergency brake hand lever actuating shoes expanding within large drums attached to the rear wheels.

Unusual care has been taken to minimize the attention to oiling and greasing, and so far as is possible grease cups have been eliminated and a special type of self-lubricating bearing has been used. All the bearing surfaces are ample and all wearing parts are large and made enduring. The fuel tank has 15 gallons capacity, and the feed is by gravity. The cooling system will require eight gallons of water to fill and the oil reservoir for the engine will hold one gallon. In the construction of the chassis all the bearings, save those of the motor, are either ball or roller, and these are of large size.

The motor and gearset are protected against chassis strains or distortion by being mounted rigidly in a sub-frame which is coupled to the main front by a yoke and lug that supports it, while at the rear the frame is carried by two widely separated supports, the effect being a perfect three point suspension. The same support has been used in the five-ton truck with



The Exhaust Side of the Pierce-Arrow Two-Ton Truck Motor.



The Transmission Gearset and Control Levers of Pierce-Arrow Two-Ton Truck.

much satisfaction, but the use of the sub-frame has simplified and strengthened the installation. In every detail the machine has been well thought out and designed for hard service.

The chassis as sold includes the running gear, the mechanism and the tires, the paint being lead color. The equipment includes the driver's seat, dash and footboards, front mudguards, dash and tail lamps, horn, set of hand tools and the metal clips for attaching the wood sills and body to the chassis frame. With a standard body the loading space is 10 feet six inches length and 72 inches width, and the total load that will be admissible on the chassis, including the body, is 5200 pounds.

TWO MONTHS MAKING DELIVERY.

Sixty Days Necessary for Shipment of Stewart Machines to Buenos Aires.

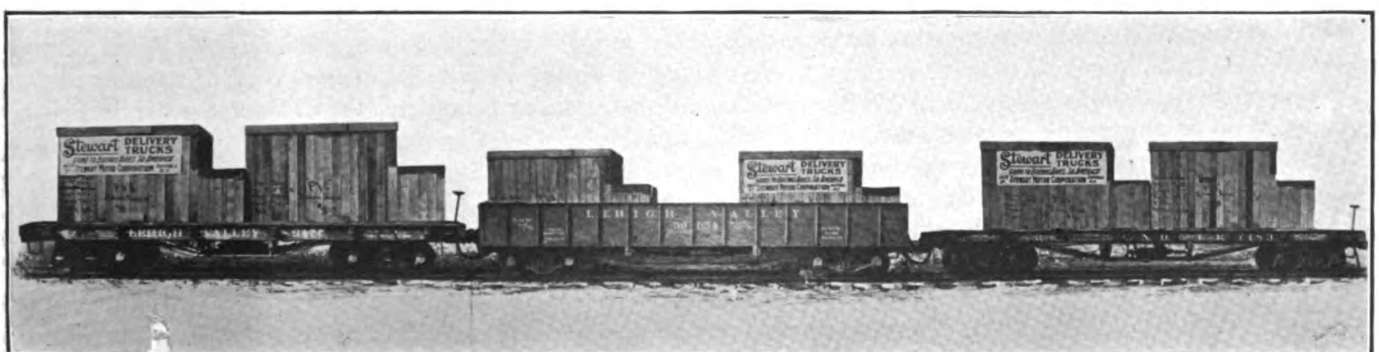
The difference in transportation facilities is greatly emphasized when one contrasts the time necessary for making delivery in any of the European ports and in Argentina, this being due largely to the slower vessels and the fact that the South American lines generally make calls en route. This difference has been especially noted by the manufacturers, who have sought to develop foreign business, for not a little depends so far as the sales are concerned upon the ability of the agents to make deliveries within a period that may be considered as reasonable by the purchaser.

The steamship lines between New York and the southern ports in South America are few and the sailings are at considerable intervals, but while this is true of America, the same condition obtains very generally in Europe and thus far there is no great advantage for the European manufacturers. For the delivery of machines from the factory at Buffalo, N. Y., to the dock in Buenos Aires, Argentina, the Stewart Motor Corporation has found that 60 days is necessary under ordinary conditions. The vehicles are carefully crated and carried on flat cars to New York, where they are transferred to the steamers, but practically all of the time the vessels are at sea.

The steamers are freighters and carry passengers incidentally, and make stops at many of the ports, and as freight must be landed time is required in every instance. Because of the long time at sea unusual care must be taken to prevent the effects of the salt air, and the crating must be very substantial. The company is making shipments frequently to Cuba and the West Indian islands and to Brazil, Uraguay and Argentina.

W. S. Van Clief of Port Richmond, N. Y., a village of the borough of Richmond, New York City, is a lumber dealer, and he has used a Peerless for nearly a year in making delivery to his customers. He uses dead wagons in the yard and these are loaded and made ready for the truck. As the machine is brought to the yard it is backed to a wagon and the lumber is moved onto the truck by a roller at the rear operated by a hand crank and by floating rollers mounted above the deck of the platform. The dead wagon has similar equipment to start the movement of the lumber on it. The load may be bound or merely stacked. However it is placed on the dead wagon one man can handle it when loading, and it can be unloaded by the same means. During the time it has been in use the truck has been driven 10,175 miles on soft dirt roads and has hauled a daily average of 16 tons of lumber. Its maximum day's work has been 65 miles. During the year the truck has been out of service for three days that maintenance work could be done.

The report of the receiver in bankruptcy of the Lansden Company shows that that company has assets of $304,000 and liabilities of $193,000.



Six Stewart Delivery Wagons Leaving Buffalo for Delivery at Buenos Aires, Argentina, Which Usually Requires About 60 Days' Time.

ANNUAL NEW YORK ELECTRIC VEHICLE SHOW.

THE annual New York Electrical Exposition and Motor Show will take place at the Grand Central Palace, Lexington avenue and 46th and 47th streets, New York City, beginning Oct. 15, and it will be concluded the evening of Oct. 25. The exhibition will be under the management of George F. Parker, who has directed these shows for several years, and the plans have so far advanced that it can be definitely stated that it will be larger and better from every aspect than any previously held.

While the show will be devoted to the general promotion of the use of electric current for power, lighting, heating and for manufacturing and household use, a very large part of it will be given over to the display and demonstration of electric vehicles and of facilities for their use, care and maintenance. The Grand Central Palace has an exhibition floor space of approximately 140,000 square feet, and three stories will be utilized for the show.

One section will be given over to a display of electric pleasure cars, another for electric freight wagons and trucks, another for exhibition of accessories, equipment and supplies, a fourth to a track where the machines can be exhibited in motion, a fifth to a model garage, which will be fitted with perfected charging apparatus and service station equipment.

The demonstrating track will be on the third floor of the building and this will be of sufficient width for two vehicles to drive abreast. The track will be set off from the remainder of the floor by brass railing and it will be oval in form. The circuit will be 100 yards. The vehicles can be brought to the floor by elevator and tried on the track under the direction of competent drivers, and this same track can be used for the instruction of those who desire some experience before venturing into street traffic with their machines.

Within the track will be a metal fireproof garage, which will be erected by Andrew Gries & Co., and this building will be a model in every respect. It will be equipped with mercury arc rectifiers by the General Electric Company, with charging panels by the Westinghouse Electric and Manufacturing Company, and with a converter by the Wagner Electric Manufacturing Company. The plans for the garage and its equipment have been developed by a committee representing the New York Electric Vehicle Association, and this committee will conduct the garage during the exhibition.

The intention is that vehicles will be received at this garage as at any public service station, and that they will be stored, charged and given the same attention that would be entailed by daily use. The station will be in charge of a competent manager, who will have the assistance of trained mechanics and electricians. Every work that would be necessary in connection with the use of vehicles or the administration of a garage will be carried on, and there will be an approved system of records that will afford the precise information that is considered desirable to insure economy and efficiency.

The garage will lack nothing in equipment. A large electric display sign will attract attention, and danger warnings will be conspicuous. Besides the charging apparatus, the battery room, the repair department, the stockroom, the washstand, vacuum cleaners, polishing motors, electric air compressors and tire pumps, and the like will be shown. In this garage will be stored the machines of the exhibitors that will be used on the track for demonstrating purposes. Each exhibiting company is expected to have a man attached to the garage for demonstrating, and there will be a special corps of demonstrators under the direction of the New York Electric Vehicle Association committee.

For the benefit of those who may consider engaging in business as manager or owner of electric service stations the repair shop will be equipped with an exhibit of lathes, presses, drills and other machine tools necessary or desirable in automobile repair work made by the United States Electric Company. The battery room will be equipped with complete sets of batteries furnished by the Philadelphia Storage Battery Company, the Electric Storage Battery Company, the Gould Storage Battery Company and the Edison Storage Battery Company.

Within the track will also be a raised platform where an orchestra will be stationed, and musical programmes will be given each afternoon and evening. It is also probable that a series of games will be a feature of some of the days, these being of a character in which the automobiles can be used.

On the main floor the different manufacturers will have exhibition space and will show machines, in some instances both pleasure cars and wagons and trucks, and in others simply the one line produced. From the number of exhibits now assured it is certain that the showing of vehicles will be the largest ever seen in New York.

The committee of the New York Electric Vehicle Association in charge of the automobile department of the exhibition consists of E. W. Curtis of the General Vehicle Company, J. B. Cafferty of the General Motor Truck Company, Nathaniel Pratt of the Baker Motor Vehicle Company, S. W. Menefee of the Anderson Electric Car Company, C. Y. Kensworthy of the Rauch & Lang Carriage Company, Charles A. Ward of the Ward Motor Vehicle Company, W. R. Chandler of the Holt-Chandler Company, W. C. Poertner of the Poertner Motor Car Company, J. M. Barrett of the Automatic Transportation Company, Harvey Robinson of the New York Edison Company and H. C. Fling of the New York Electric Vehicle Association.

The statement is made that the Great Western Automobile Company, Peru, Ind., is to build a motor truck, and that designs for the machine are now being prepared by a Detroit engineering firm.

PEERLESS TRUCK MEETS ARMY TESTS.

Superiority to Foreign Machines Proven by Work in Philippine Islands.

The Quartermaster-General's Department, U. S. A., operating in the Philippine Islands, must necessarily transport large quantities of supplies and material, and with the improvement of the highways the officers have naturally turned to motor vehicles as being superior in every way to any other form of transportation, for the railroads reach only the principal centres of a few of the principal islands. The headquarters of the department are at Manila, and this is the principal point of distribution. One of the stations is Baguio, and this may be reached by both road and railroad.

For transportation purposes the department purchased a number of specially built motor trucks of French build, because at that time no machine immediately available was regarded as powerful enough to do the work. These were rated as two tons capacity, but were fitted with motors and radiators of the size installed in five-ton trucks. One old American truck was used, the power plant being augmented by an engine taken from a steam touring car and coupled to the jackshaft. As might be assumed, this combination of steam and gasoline was not a mechanical perfection, although it could do the work.

The department tried a Peerless three-ton truck and it gave excellent satisfaction, climbing Benguet hill, an exceedingly steep ascent, with varying loads. It consumed less fuel with three and four-ton loads than did the De Dion-Bouton two-ton machines, and during the trial carried from 6340 to 10,900 pounds. With all but the largest overloads the truck was never operated on the low speed, and it did not heat excessively, though only two makes of touring cars have ever climbed the hill without stalling because of overheated motors. On one run with a load of 6340 pounds the truck made the distance in three hours and 20 minutes, which was faster than the train schedule.

Following the experiment the department purchased the only two Peerless trucks in stock in Manila, and negotiated for several others. The power of a truck that would carry a two-ton overload up a hill that no other machine had climbed with a full load has seemingly sufficiently demonstrated the quality of American machines and has probably ended a demand by the army, at least, for European machines.

G. W. A. Wells, formerly chief engineer of the Adams Express Company, has been placed at the head of the newly created department of investigation by the Autocar Company, Ardmore, Penn. The purpose is to investigate and study the delivery and transportation departments of concerns, with a view of determining the number and size of motor or animal units necessary to afford the most efficient service. Mr. Wells was for 10 years connected with the Adams Express Company and was active in the motor installations, that corporation now utilizing several hundred wagons and trucks. He had charge of the purchase, maintenance and operation of the machines, and designed and established the different garages located in various cities. Mr. Wells is a member of the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, the Society of Automobile Engineers and other well known organizations, and is widely known in transportation work.

Peerless Three-Ton Truck in Service of the Quartermaster-General's Department, at Baguio Station, P. I., with a Load of Iron Pipe.

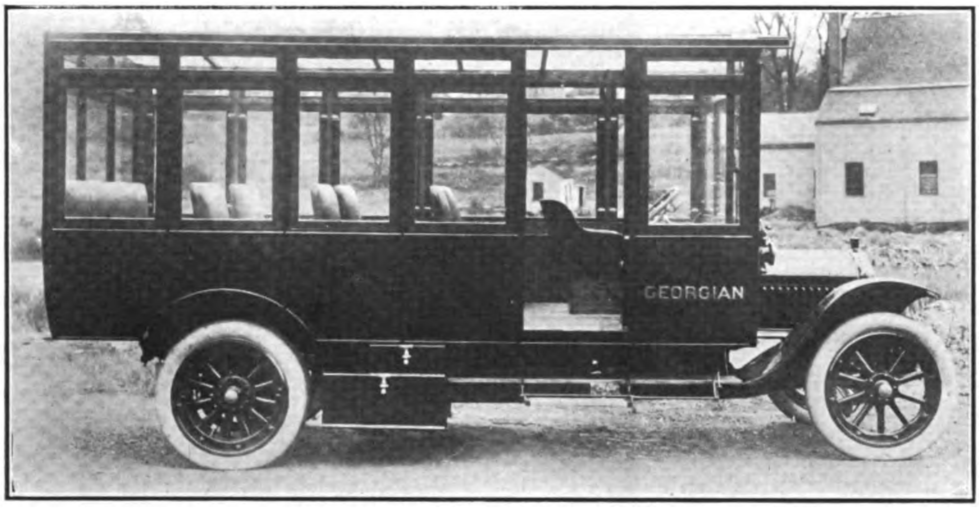
During a recent series of demonstrations to breweries in Philadelphia, a five-ton Atlantic electric truck, with one charge of a 25-MV Hycap Exide battery showed exceptional mileage. In work for C. Schmidt & Sons one run was to Bristol, with city work, covering 46 miles; another to Roxborough and return and to Germantown and to Roxborough and return was about 49 miles; and a third fully and partly loaded and also carrying a partial load of empty barrels was to Chester, to Ardsmore and to Bristol and return, a distance of 52 miles. In work for F. A. Poth & Sons, one day's demonstration was a trip to Frankford, Bristol, Newportville and Tacony, returning to Bristol, thence to Holmesboro and back to the brewery, making 57.5 miles, using 360 ampere-hours of current. The truck was run on fine roads with four ampere-hours a mile, in city grades with six ampere-hours a mile, and on hills with seven ampere-hours a mile, which is regarded as being very economical.

GLASS-ROOFED MOTOR 'BUS.

Unique Vehicle Designed for Service Over Route of Paul Revere's Ride.

A motor omnibus of decidedly unusual body design has been constructed for the service of the John Rockett Taxicab Company, Boston, Mass., which is intended for affording the passengers a very wide opportunity for observation, as well as meeting with all the requirements for comfort and convenience. The company will use the machine in whatever service it may be best adapted for, but its principal use will be in taking sightseers over the famed route that was ridden over by Paul Revere when he roused the Colonists the night before the battle of Lexington, that conflict that inaugurated the successful struggle for American independence.

The 'bus has a standard White 3000-pound chassis and the body is built to extend from the dash and considerably overhang the chassis frame, there being one wide entrance at the right side that may be closed by a sliding door. The step may be raised or lowered by the driver whenever occasion requires. The drive is left side and the machine is entirely controlled from within the body. The body will accommodate 22 passengers, there being transverse seats with an aisle between all save the back seat. The side windows are removable so that there may be unobstructed view at either side, and when removed they are carried in a compartment beneath the chassis frame. To utilize the full capacity of the body there is a hinged drop seat between each set of seats, which may be raised when required, and lowered when the aisle is used for movement of the passengers.



Glass-Roofed Sightseeing Omnibus in Service of the John Rockett Taxicab Company, Boston, Mass.

The body is surrounded by windows and the roof is also of glass, the sections being so secured as to make a very strong and enduring construction. The glass is such as is used in fireproof construction, being reinforced with wire, and in the event of accident there could be no damage or injury from breakage. This roof affords light almost the equal of an open body. The machine is devoid of running boards, and the tires are carried in a compartment. The body is very sightly and it has attracted much attention because of its departure from ordinary constructions.

MAY ACQUIRE ALCO PLANT.

Providence Capitalists Make a Proposition for Its Purchase to the Company.

The directors of the American Locomotive Company are now considering a proposal made by a group of Providence capitalists headed by William H. Draper and Michael W. Norton, the latter being well known as the head of several taxicab service companies, which includes the sale to them of the unfinished machines and material now in the plant. Messrs. Draper and Norton have contracted for 26 Alco trucks to be delivered to them by Oct. 15, and these machines are to be the nucleus of a fleet to be operated by a trucking company doing business in Providence and vicinity.

The original plan for discontinuance of the manufacture of Alco machines comprehended the operation of the plant until the 300 trucks in process of construction were completed, as well as the production of sufficient parts to meet all requirements of owners of Alco machines for a period of five years. The expectation of Messrs. Draper and Norton is that they will be joined by other capitalists, some of whom are now interested in the American Locomotive Company, and that a company may be formed that will take over the plant and continue the production of machines. Negotiations to this end are now in progress and it is probable that definite announcement may be made in a few days.

The Ebling Brewing Company, New York City, is using three Atlantic trucks that have Edison A-12 batteries, and on routes where from 40 to 45 miles a day are required for the work. In tests of the machines upwards of 53 miles have been driven on a single battery charge.

The Kougle Auto Company, that has been engaged in a painting and repairing business at Indianapolis, Ind., has acquired the control of the Auglaize Motor Car Company of New Bremen, O., and will move the plant to Indianapolis, where the Auglaize delivery wagons will be produced under the name of the Kougle machine. The company is erecting a new factory and will later on produce several types of motor vehicles.

COLD STORAGE BAKER TRUCK.

Electric Machine with Special Body for Porto Rican Ice Company's Service.

The Porto Rico Ice Company, at Hielo, P. R., is an important industry in Uncle Sam's West Indian possession, for in that island the temperature is always so high that ice is one of the necessities of life with natives of the United States and other countries. Its use is imperative for the preservation of food, the preparation of drinks and in the event of sickness, and with the increase of the white population the demand has impelled the delivery of ice to points where it may be distributed conveniently. The Hielo company has a plant where ice is produced by mechanical methods, and it has located a sub-station six miles distant. To transport the ice from the plant to the station without material shrinkage was a problem that was met by the purchase of a Baker 3.5-ton chassis on which a specially designed body was built by the Baker Motor Vehicle Company, Cleveland, O.

The company decided that an electric machine would best meet its requirements from the fact that it must have extreme endurance, the height of simplicity and such construction that it could be handled and driven by men having no special mechanical knowledge. As the company constantly utilizes power the current necessary could be produced without additional expense.

The truck chassis is a standard production, but the body as it is built is practically a refrigerator, and it is designed to preserve ice for long periods. Only those who have experience with the climate can understand the needs. The front, sides and roof have double walls that are four inches thick, with the spaces packed with ground cork. The floor is 4.5 inches thick and it is built of inch oak lumber, under which is a layer of asphalt composition 1.75 inches thick, and below this is a layer of cork board one inch thick laid on Georgia pine board .75 inch thick. The rear of the body is closed by double doors and a high tail gate, these being of standard refrigerator construction, with double walls and packed with cork. Any one or all of these may be opened to load or unload the truck. Near the rear end of the body may be seen the drainage outlets, which are trapped so that warm air will not be admitted to the body, and when the doors are closed the body is as tightly sealed as is a refrigerator or ice box. It is practically air-tight, and in it ice can be carried many miles with very little shrinkage. As ice is always expensive in hot countries the wisdom of the body construction is apparent. Within the body is a series of adjustable crossbars by which the ice may be held in place, so that it will not shift in transit. The rear step is folding. In the illustration it is shown dropped for work, but it may be raised to prevent any person riding when the machine is moving. Back of the seat of the driver is a ticket box in which may be deposited the tickets received for ice, for the drivers are not permitted to handle the money, and the customers pay with coupons that are purchased from the company. This box is not seen in the illustration.

Baker Electric Truck Equipped with Specially Built Body for the Delivery Service of a Porto Rican Ice Company.

NEW EDISON BATTERY CELL.

Type Developed for Use in Pleasure Cars and Light Delivery Wagons.

A new battery cell that is known as type A-5 is now built commercially by the Edison Storage Battery Company, Orange, N. J., this having a rating of 187.5 ampere-hours and is intermediate between type A-4 with 150 and type A-6 with 225 ampere-hours capacity. The cell is designed for use in pleasure cars and light delivery wagons and such purposes as where the amperage of the type A-6 cell is not needed. It is particularly adaptable for batteries for 1000-pound wagons, industrial and floor freight trucks.

In every detail the cell resembles the larger and smaller types and it is sold with the guarantee that it will deliver its full rated capacity at the end of four years, provided it has received the attention suggested by the maker. These cells are now being produced in quantities to meet the demand and deliveries can be made as promptly as with the other sizes.

With capital of $250,000 the National Motor Truck & Manufacturing Company has been organized at Gibsenburgh, O., and it is proposed to build a plant at that place, and the company will use the patterns and patents of the Toledo Truck Company of Toledo, O.

PLANS FOR CHICAGO CONVENTION OF E. V. A. OF A.

THE fourth annual convention of the Electric Vehicle Association of America will take place at Chicago, Ill., Monday and Tuesday, Oct. 27-28, and it will be the first meeting of the organization ever held west of New York City. The convention of 1912 was held at Boston during the electric exhibition in that city.

The convention plans were placed in the hands of a general committee named early in the year and they have so far progressed that a general outline of the proceedings can be stated. This committee consists of the following members: Chairman, Homer E. Neisz, Chicago; G. H. Atkin, Chicago; D. C. Atlington, Chicago; Day Baker, Boston, Mass.; William G. Bee, Orange, N. J.; Charles Blizard, Philadelphia, Penn.; W. H. Blood, Jr., Boston, Mass.; Louis E. Burr, Chicago; Hayden Eames, Cleveland, O.; L. A. Ferguson, Chicago; C. B. Frayer, Chicago; W. W. Freeman, Birmingham, Ala.; John F. Gilchrist, Chicago; Uri Grannis, Chicago; James T. Hutchings, Rochester, N. Y.; George H. Jones, Chicago; G. H. Kelly, Cleveland, O.; William P. Kennedy, New York City; E. W. Lloyd, Chicago; W. J. McDowell, Chicago; E. S. Mansfield, Boston; Harvey Robinson, New York City; William L. Rudd, Chicago; P. H. Schaffner, Chicago; Frank W. Smith, New York City; F. M. Tait, Dayton, O.; L. E. Wagner, Chicago; P. D. Wagoner, New York City; Arthur Williams, New York City; E. E. Witherby, Chicago.

This committee has been assisted by the following sub-committees, which have been actively engaged in the work of preparation: Finance, George H. Jones, chairman; Uri B. Grannis, G. H. Atkin, E. E. Witherby, Harry N. Fowler. Entertainment, L. E. Wagner, chairman; C. B. Frayer, P. H. Schaffner. Exhibits, E. E. Witherby, chairman; G. A. Freeman, T. W. Barnes. Transportation and garage exhibition, Louis E. Burr, chairman; D. E. Whipple, Ralph Temple, Harry Salvat, Penrose Reed.

The committee has received assurances that justify the belief that there will be approximately 300 members in attendance, and there will be a very strong representation from the New England and the New York associations, while a considerable number from the South and West will probably be present. The morning of the first day will be given over to registration at convention headquarters at the La Salle hotel, and at noon there will be a luncheon at the hotel, probably with some of the Chicago and other western central stations as hosts.

The first session of the convention will take place at the hall of the La Salle hotel beginning at 2 in the afternoon, and the second and third sessions will take place the morning and afternoon of the second day. The first session will be devoted to the address of President Arthur Williams, the reports of officers and committees, and the presentation of three papers. The intention of the committee on papers is that there shall be three papers read at each session, and the expectation is that these will be fully discussed. The election of officers of the association will take place the second day and the announcement will be made, in all probability, at the third session.

The members will have a dinner at 6 at the La Salle hotel the evening of Monday, and following this will make a trip by automobile to the Fashion garage at 51st street and Cottage Grove avenue, where there will be an exhibition of electric passenger cars and storage batteries and charging apparatus. There is also probability that trucks and wagons will be shown at the garage, but this has not as yet been definitely decided. After visiting the exhibition the members will return to the La Salle hotel for a smoker and cabaret entertainment, which will conclude the evening's formalities.

Tuesday at noon the Chicago Section of the Electric Vehicle Association will have its regular luncheon at the La Salle hotel, and the members and all the out-of-town visitors will be the guests of the local organization.

A general invitation will be extended to the public that may be interested in electric vehicles to attend the sessions of the convention, for it is the belief of the committee that the papers will not only be of especial interest to those identified with the industry and trade, but will be valuable to those now using, and who purpose to use, electric machines for either passenger or haulage work. During the convention rooms on the 18th floor of the La Salle hotel will be used as headquarters and for such exhibition purposes as may be required by builders of vehicles and of equipment and accessories.

The papers to be read will be diversified in character and it is expected that these will deal with subjects that have been given special attention by the association, and in addition the reports of the committee will be of special importance. The papers will be generally promotive and will be in harmony with the purpose of the association to unite all manufacturing, selling and central station interests in a campaign that will bring about a more general use and a better knowledge of electric vehicles.

In building an oil pipe line from the Midway oil fields in California to tidewater at San Pedro, 18 White motor trucks, made by the White Company, Cleveland, O., supplanted 500 Missouri mules. They crossed 40 miles of desert sand, running nine miles on each trip on river bottoms, and with every load climbed altitudes as high as 8500 feet. The total of the hauling contract was 700,000 ton-miles. Before much progress had been made it became necessary to build bridges, put on Indian drivers who could stand the intense heat, and construct desert roads of sage brush and eucalyptus branches. Five of the trucks had previously been driven 100,000 miles each.

ELECTRIC VEHICLE PRACTISE.

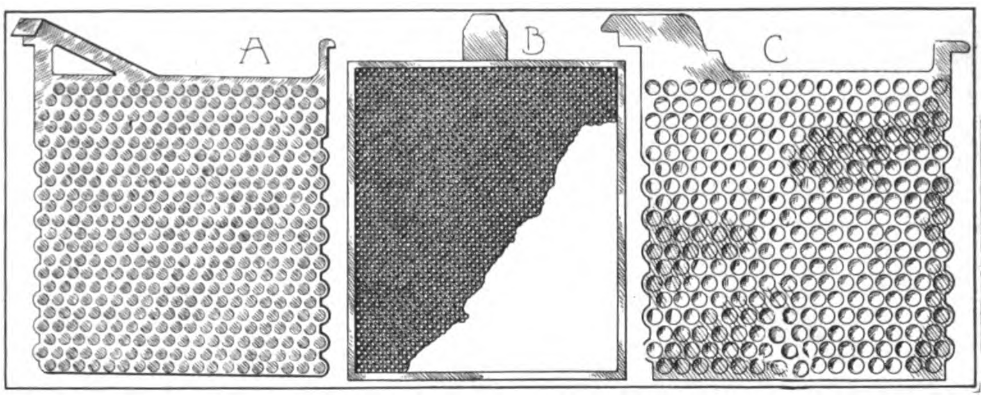
Factors in the Design and the Construction of the Acid Cell Plates of the Plante and Faure Types---Qualities of Several Productions and Conditions That Cause Deterioration---Progressions in Increasing Capacity.

By William W. Scott.

CONSIDERING the formation of the plates used in the acid or lead battery, it is evident that designing has become an engineering proposition, in which the purpose of the designers is, first, to produce what will have endurance, capacity and the lightest weight consistent with the requirements stated; and second, the lowest manufacturing cost that is possible with the quality necessary. Hundreds of experiments have been made with reference to materials and processes, and very careful investigation to obtain the properties believed to be essential. It is apparent that the chemistry of lead battery cell construction is a subject that has no end of ramifications, and research has developed some surprising results, but this information has little if any practical value for the user of the cells, who, were he possessed of this information, would have no actual use for it.

The engineer who designs a storage battery cell does so on the basis of capacity, and the unit is the ampere-hour, this being the equivalent of one ampere flowing for one hour. This refers to the discharge rate, and so the ampere capacity of a cell is the product of the rate of flow in amperes when multiplied by the number of hours that the specified current rate is continued. But as discharge is or may be variable, it will be understood that this capacity can be materially varied. To more closely approximate a definite value a standard has been recognized, this being discharge in eight hours and at a temperature of 70 degrees Fahrenheit, and this is the accepted basis of cell standards of the day. In other words, the capacity is given as that which will afford a stated flow of current for eight hours without the voltage falling below the minimum voltage that is allowable.

Bearing this in mind, and with the given amperage of a cell, the standard rating of current output will be the amperage divided by eight, so that a 120 ampere-hour battery cell will discharge 15 amperes an hour for eight hours continuously, or, theoretically, for eight hours' time, no matter how divided, at the same rate. In designing a cell the capacity is determined by the area of the active material of the plates that will contact with the electrolyte, there being, of course, accurate knowledge of the quality of the active material, and the positive plate area is that accepted, for aside from a two-plate cell, there is always one more negative than there are positive plates in an element. The area is that covered by the electrolyte, the product of the length and width multiplied by two, for both sides are equally active, is given in square inches, and computed in this manner it will be understood that only the surface of the positive plates is considered. So the greater the surface area the greater the capacity of the cell. It is customary with manufacturers to designate cells by letter, number or combination, that is distinctive, these sometimes indicating voltage and amperage, but this is not often the case with vehicle battery cells. The voltage is assumedly the same, or practically the same, with all lead cells, and it may be placed approximately at two volts. When a battery is designed for any particular work a sufficient number of cells is used so that coupled in series the required

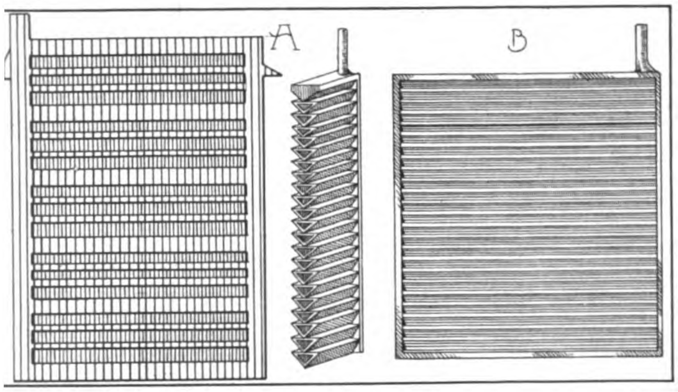


Forms of Construction: A, the Manchester Positive Plate; B, the Exide Negative Plate; C, Another Type of Manchester Plate.

voltage is obtained, and the amperage will be that of the single cell. That is to say: Taking 44 cells with the normal voltage of 2.5 volts when fully charged we have a battery voltage of 110 when connected in series, and the amperage may be, to illustrate, 250 amperes, which is the amperage of a single cell. It will be remembered that the voltage is the pressure of the electromotive force of the cell, and the amperage is the volume of flow of this force.

The design of the cell being determined, the materials are chosen on the basis of known capacity of the element. For instance, it is essential to have the cell as light as is practical, and as there is a limit to the weight of a substantial jar, and the quantity of the electrolyte must not be less than a given volume, the only practical reduction appears to be in the weight of the plates. It may be said that the endeavor of engineers has been directed toward this end in the con-

struction of cells designed for vehicle battery use. But as there has also been a desire to increase the amperage capacity of the cells, this has been very generally



Forms of Construction: A, the Khotinsky Plate; B, the Winkler Plate.

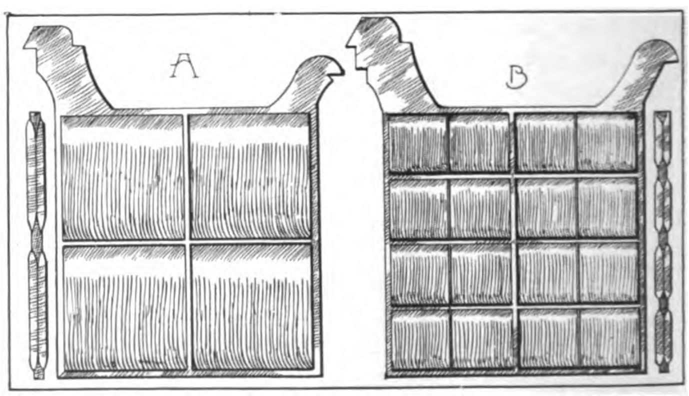
sought by increasing the surface area of the element, which has been accomplished by using a greater number of thinner plates.

Where the battery is used for a stationary installation the weight is secondary, and the cells may be larger and have the full endurance that is expected of the thick plates, but where the battery must be carried, as in a vehicle, the purpose is to reduce the weight so far as is possible and increase the amperage by the use of thinner plates, that will, when used in larger number, expose a greater surface area to the electrolyte. This demonstrates the importance of plate design and construction. In consideration of the types of Plante or formed plates the processes of construction have been briefly outlined, the surfaces being shaped by scoring, swedging, grooving, laminating or casting, the intention being to increase the area so far as may be practical, and the size and shape of the cuts in the plate surface can only be determined by careful experiment. It is necessary to preserve strength, and it is also necessary to have the plates light and sufficiently rigid so that they cannot be distorted by the expansion and contraction from the influences of the electrolyte, for the formations in the channels will be changed as the cell is charged and discharged. Not only this, the formations must not be thrown off, and the channels must be of a form that will best retain them. There is a possibility of the positive plates being subjected to material stresses, through the formation of an excess of oxide, and the distortion may bend (buckle) or expand the plates slightly in a transverse direction and considerably in a longitudinal direction.

Consequently every engineer designs the plates to best meet with the requirements, and the purpose is to minimize the effects described and insure against such changes as would cause deterioration of an abnormal nature. The thickness of the coating of peroxide on the positive plates depends upon the design, and this may be thin or thick. The thin coat is regarded as producing a more uniform voltage on discharge, allows greater rapidity of charging and discharging, and is especially desirable where the current rates are high. But there is a greater degree of surface expansion and contraction, and there is greater probability of the thin formation becoming loosened, so that for cells that are to be charged to maximum and discharged to minimum capacities the thick coating is considered the more enduring. Observation seems to have established that there is less corrosion of the plates where the channels are filled with active material than with the formed type, and there is less probability of distortion through the corrosion. Lead peroxide has greater volume than the lead from which it is formed, and it is this change in volume that causes damage or deterioration.

The Plante plates are all first formed as positives, and after this process the selection of the negatives is made and by a reversal of the process these are transformed to sponge lead. While the original forming was by electrolysis alone, the forming is now generally by chemical, electro-chemical, or amalgamating processes, and of these the second is preferred, and it is maintained to yield the most satisfactory and practical results. Chemical processes are not often used, and amalgamating is seldom employed. The electro-chemical process is to clean the plates, and electrolytic action with different forming solutions causes a rapid formation of the peroxide. Care is taken to eliminate the salts and acids, and then by reversal of the current in a sulphuric acid electrolyte the negative plates are transformed to sponge lead. The processes that may be included under this division are exceedingly numerous, and in many instances differ widely. The efficiency of these methods depends upon conditions and the care taken in treatment, and it would not be practical to state that even under careful supervision exactly uniform results could be obtained, for there is variance in the materials and in the judgment of those utilizing them.

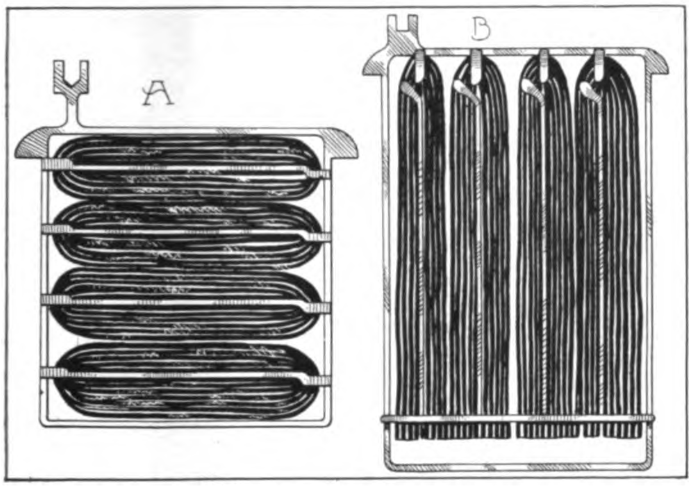
Plates of the Faure type are primarily grids or frames of lead combined with other metals to secure rigidity, the alloys varying from 88 to 98 per cent. of lead, and from two to 12 per cent. of antimony, there being a lower ratio of antimony in the positive frames. It may be said that a very general proportion is about



Forms of Construction: A, the Gould Negative Plate; B, the Gould Positive Plate.

96 per cent. of lead and four per cent. of antimony, but frames are sometimes made of lead, antimony and mercury and sometimes of lead and tin. When more than

five per cent. of antimony is used the frames are brittle and have no ductility, and may be more readily broken through distortion. The value of the composition is chiefly in its power of resistance to oxidization.

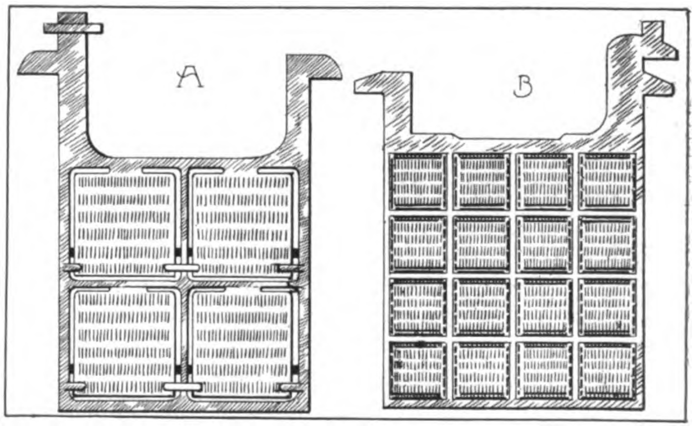


Forms of Construction: A, the Blot Plate with Transverse Laminae; B, the Blot Plate with Vertical Laminae.

It is apparently agreed by authorities that the Faure plate is superior to the Plante type, with reference to capacity a unit of weight, and that the pasted plate can best be used in cells where minimum weight is required. The active material applied to the plates has a degree of porosity and it is penetrated by the electrolyte, exposing a greater surface area, but it has not as high a quality of cohesion and it will, through the alternation of expansion and contraction, become loosened and will gradually disintegrate, this being particularly true of the positive plates. The pasted plate in continuous service has not the same life as the Plante form, and while the endeavor of engineers has been directed toward improvement, the relative values as regards endurance have not been changed. There is no doubt, however, that some forms of Faure plates are more enduring than others. For the protection of plates differing methods have been devised, generally in the form of envelopes and occasionally by shaping the frames.

Many forms of frames are used by manufacturers, each of which has been adopted after careful observation and experiment, and is expected to afford the strength and retaining qualities desired. These may be classified as different grids with either transverse and longitudinal, and sometimes diagonal, members, or they may be with few or many cross members, and occasionally with slots or openings to allow the expansion and contraction of the plates. Some examples of these have been shown, but there is variance with practically every type of cell made, and often distinctive claims are made for the plates as being little affected by the changes during the periods of charging and discharging. In the construction of these frames the purpose is to minimize the weight and secure the greatest strength, making it possible to have the maximum area of active material and insure a satisfactory conductivity. Where the plates are thin the designs are worked out with extreme care to provide the required rigidity and strength. In the production of these plates the active material in a plastic state is placed into the grids and is firmly compacted, often under pressure, to entirely fill the frame, so that when dried or solidified the plate is smooth and even. These lattice-form frames are of two types, those with cross members the full thickness of the plate, and those with the cross members half the thickness of the plate, each intersecting the space formed by the other, dividing it into smaller spaces at the back and affording a support for the active material. These grids are sometimes with horizontal and vertical members, and sometimes diagonal. The frames are formed so that when the material has solidified it is locked into the spaces and cannot be dislodged.

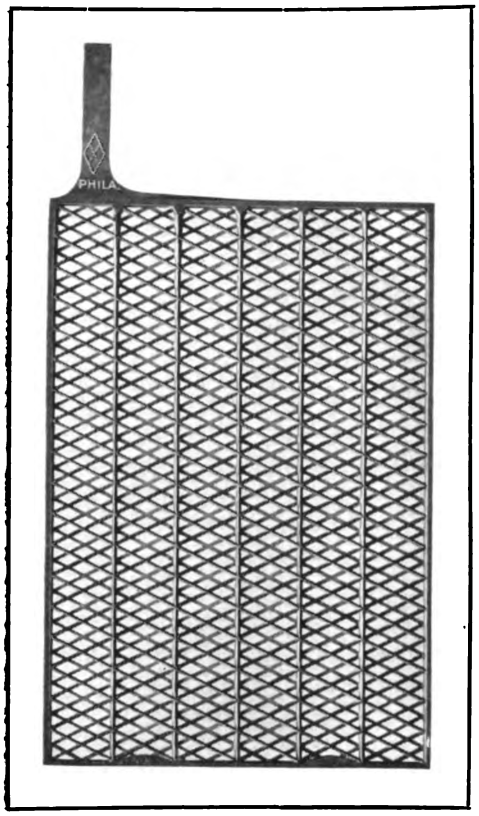
Another class of frame is that in which the cross members are the full thickness of the plate, with occasional heavier members to afford the desired rigidity, these members so shaped as to retain the solidified active material. Still another form is that in which the frames are in divisions, separated by slots of considerable size, and there are the corrugated or channelled frames without perforations, combination of the channelled and perforated types, plates with members shaped to lock the active material, as well as frames that are cast around the active material, and the so-called "box" negatives. The last mentioned are frames with square openings that are filled with active material, and one side of the grid is covered with a perforated sheet of thin lead. Two of these are assembled with the pockets facing, being riveted together, so that the active material is held within the pockets, and the electrolyte reaches it through the perforations in the thin sheets of lead. Attempts have been made to make frames of non-metallic substances to secure lighter construction or to the better retain the active material, but these have not been sufficiently successful to regard them as practical forms. One example of this has been illustrated, this being frames of unglazed porous earthenware with a series of pockets on one side and channelled on the other. The pockets were filled with active material to project above the plate. Two of these plates with a sheet of lead between them formed an electrode, the active material contacting



Forms of Constuction: A, the Unit Accumulator Positive Plate; B, the Bijur Positive Plate.

with the lead sheet, this forming the conductor between the pockets.

The frame is an exceedingly important part of the cell and the design is a very large factor in its efficiency, and extreme care is often directed toward securing the necessary form, alloy and method of formation. It has been said of one manufacturer that two years' constant work and a very large expense were necessary in the perfection of the plate now used, but this has been abundantly justified by the very high results obtained.



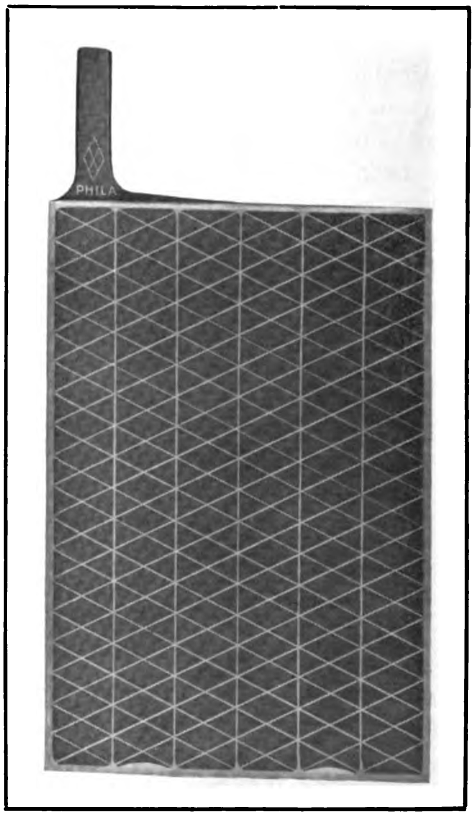
The Philadelphia Thin Plate "Diamond Grid," on Which the Active Material Is Applied.

In some constructions Plante type plates are used for the positive and Faure plates for the negative members of the element. The base of all active materials used are powdered lead or oxides of lead, either massicot, red lead or litharge, and the preparation is sometimes mixed with a proportion of carbon (which increases conductivity), pulverized pumice stone (which increases the porosity), and long asbestos fibre, the last being intended to strengthen the structure, although not adding to its qualities. One of the first composition was litharge, mixed with sulphuric acid, but generally the positive plates are filled with minium or red lead, and litharge for the negative. In the making of the plates the soft composition is forced into the grids, grooves, channels or perforations, and after being solidified by pressure they are dried in the open air from one to two weeks, but often they are dried in ovens at a temperature of about 200 degrees Fahrenheit, being subjected to a bath of sulphuric acid to produce hardness after a certain stage of drying has been reached. The negative plates of litharge (PbO) are treated in a bath of diluted sulphuric acid and reduced to sponge lead by coupling with dummy sheet lead plates serving as anodes and passing a current of electricity through them. In a similar manner the active material of the positive plates are converted from Pb^3O^4 to PbO^2 by connecting them as anodes with dummy plates serving as cathodes.

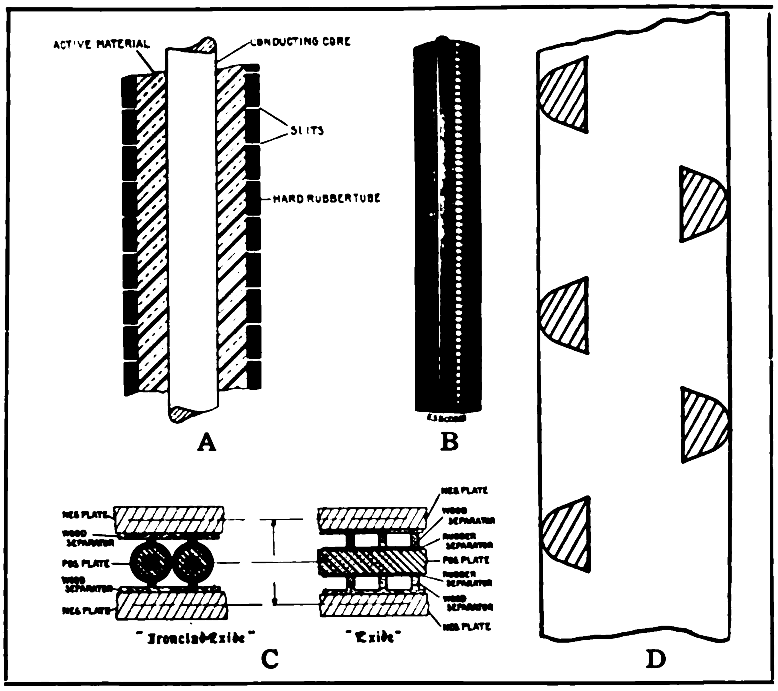
It will be seen from the above statement that the active material as applied is in a form that is easily reduced to the peroxide of lead and spongy lead required for the cells, a process that very much lessens the time and expense of production. The materials stated, however, are not always used. The compounds will differ widely and in some instances acids, alkalis, glycerines and oils are added to secure cohesion, and various substances utilized to secure porosity and conductivity. All plates made by the Faure process, that is, by pasting the active material, must be formed, and despite the best efforts of engineers, no plate has been produced that will have satisfactory efficiency unless worked individually. By this is meant that the active material cannot be prepared, treated in quantity and made ready for application, and neither can plates be made that will be practically ready for use without the electrolysis that produces the conditions in which they are useful.

Electrolytic action can be determined with great exactness, and estimate can be made of the time to accomplish certain results, but in practical working of plates more time is usually required than is indicated by formulae, this from the fact that the penetration of the plates is not always uniform, and other conditions. As an established flow of current is required, and this cannot be exceeded, it will be understood that longer periods of forming means greater current consumption.

Considering the formation of the plates, it will be realized that whether the Plante or Faure type, the negative is required to be sponge lead, and this formation has a considerable degree of porosity, the cells varying in size. The more porous the plates, the larger the area exposed to the electrolyte, and the greater the surface the more potent the activity or influence of the plate. But it is not possible in formation to determine the precise state of porosity, and while plates of a given area are regarded as having a given value, they will probably vary somewhat in potency. This variance, however, is not a material factor.



A Philadelphia Thin Plate Formed and Ready for Installation.



"Ironclad-Exide" and "Exide" Plates: A, Section of "Ironclad-Exide" Positive Plate Tube or Quill; B, Quill of "Ironclad-Exide" Positive Plate, Showing Rib That Serves as Separator; C, Cross Sections of "Ironclad-Exide" and "Exide" Plates as Assembled in a Cell; D, Cross Section of "Exide" Plate, Showing Staggered Construction of the Grid, the Small Shaded Sections Designating the Ribs.

The positive plates, if of the Plante type, have a thin coating of peroxide of lead that is retained by cohesion to the lead beneath, and the efficiency of the plates depends upon the extent to which the electrolyte will penetrate this coating. The peroxide is also porous, and if the electrolyte has free penetration the greater the activity. The coating is assumed to be uniform in depth on the plates, but it will vary considerably. The effective area of the plates depends upon the channels or grooves, and it will be seen this area can be greatly varied. Engineers determine the relative area requirements by assuming a given value a square inch of surface as established by experiments. This active material is subjected to expansion and contraction, and disintegration follows with use, so that the capacity of the plate is reduced, and the porosity is decreased from this and the accumulation of sulphate and crystals of sulphion which are not entirely dissipated by the charging.

If of the Faure type the plates are subject to the same influences that cause deterioration, and there is a gradual loss of potency that cannot be prevented. The loss is more from the positive plates than the negatives, and a broad statement would be that the life of the positive plates is from 50 to 75 per cent. of the life of the negatives. This may differ with conditions and with differing constructions, but generally speaking the negative plates may be used and be found to have good efficiency after the first set of positive plates of the element have been so much reduced as to be comparatively worthless in service. Some very interesting data relative to plate life are available, and it will be presented in the course of the discussions. Although engineers have attempted to reduce deterioration, and different forms of protection have prolonged life to some extent, there remains the stated difference between the positive and negative plates.

As the lead battery cell is used the capacity will gradually decrease, this loss varying according to care and attention. But with all conditions ideal the cell will lose in capacity, although the same, or practically the same, current will be required for charging as when new. The one exception to the constructions of positive plates referred to is the "Ironclad-Exide," made by the Electric Storage Battery Company, in which the positives are lead alloy frames with perpendicular rods extending from the top to the bottom members, these rods being surrounded by thin rubber quills in which is packed lead peroxide. Very thin horizontal slots in the rubber afford the access of the electrolyte, and the lead rods have the necessary conductivity. The lead peroxide has a larger degree of porosity than when formed on the plates, and the entire volume is assumedly potent, while the rubber quills prevent the disintegration of the active material.

Another plate that is claimed to have unusual strength, extreme retention of the active material and a high degree of conductivity, is the "Diamond Grid" form that is made by the Philadelphia Storage Battery Company. The frame is used for both positives and negatives, and, it will be noted, it is a lattice with the openings of "diamond" form at either side, the members at each side intersecting the centre of the opening on the other. When the active material is applied and consolidated under pressure the material in each "diamond" is supported by the "X shaped" members of the frame at the other side of the plate.

(To Be Continued.)

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

MOTOR TRUCK DRIVERS.

Owners of motor vehicles who have given the driving of their machines the attention the subject deserves are generally agreed that the average man who is hired as a driver believes that no other work than operating should be required of him, and, in the event of labor being exacted, is disposed to shirk it so far as he can do so without sacrificing his employment. The statement is made that a man employed as a driver of animals expects to load and unload freight as well as drive, and does this work willingly. One serious objection to those who have learned to drive pleasure vehicles, as operators of trucks, is the supposition that no other labor is necessary, and another of equal importance is the difficulty experienced in controlling their desire to drive rapidly, and consequently with indifference to the public. Between the results of the inconsiderate driving, which causes rapid deterioration of the machines, and carelessness, which causes restriction and increases liability, the truck owner must look with some doubt on men who are available, and question the advisability of hiring them.

Probably the condition can best be met by the cooperation of truck manufacturer and purchaser, the latter to send dependable men to the former for a sufficient instruction in operating and maintaining vehicles, and the builder undertaking to educate the men under careful supervision. This suggestion has worked out very satisfactorily in practically every instance it has been tried, and it might be practical for manufacturers to make such provision for the training of drivers. This would insure reasonable operators, willing workers, and longer service of the machines, and the cost of training the men would be one of the best investments that could be made.

SIZES OF TRUCK TIRES.

The builder of the motor freight vehicle has a chassis designed and the weight is estimated. The body installation is optional. The wheels are sometimes specified by the designer and sometimes by the axle maker. The tires are furnished by the manufacturer on a basis of weight to be carried. Seldom, if ever, are tires in excess of the size to carry the maximum freight. The tires might be expected to afford average service were not the owners always willing to load the vehicles to more than capacity, with the result that rapid deterioration is almost a certainty. The one objection that can be made against large sized tires is the additional cost, but no one appears to understand that these are a double insurance in that they will last considerably longer and in the end are no more expensive, while they will not be damaged by work with the truck capacity exceeded. The sale of the larger tires is not really a benefit to the tire manufacturer, for, if he were to profit, this would follow through the use of the smaller shoes, which would be worn to uselessness more quickly.

ANTICIPATING LEGISLATION.

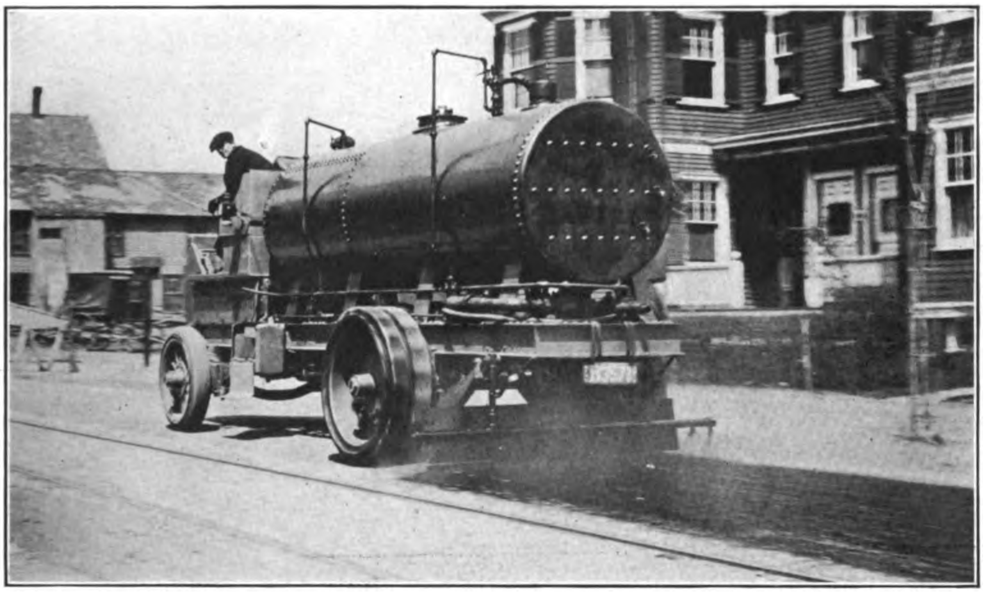
The experience with reference to legislation is a safe guide, and there is good reason in a number of states to expect well organized endeavor to impose greater taxes on machines used for business purposes. In several states bodies of truck owners, distributors and manufacturers have been formed for the purpose of promoting and protecting their interests, and these are in a position to definitely ascertain the attitude of the candidates with relation to taxation propositions. In New York, however, the state organization of the American Automobile Association is maintained by its secretary to favor restriction of the weight and size of trucks. This appears to be a decidedly inconsistent proposal, because this body has not only promoted the state highway system, but has been instrumental in the state expending more than $50,000,000, aside from local expenditures, for road improvement, all, assumedly, for the benefit of the owners of pleasure cars and all forms of horse traffic. Probably 90 per cent. of the motor wagons and trucks in use in New York, and there were about 10,000 in all registered in 1912, are used in the cities, and about 85 per cent. of the highway transportation is in cities. The proposal is to limit the truck capacity to three tons. Apparently the state association is willing to attack the owners of trucks to prevent their use of the road, to which they are equally entitled, so that the motorists may the more enjoy them.

MOTOR TRUCKS FOR ROAD CONSTRUCTION.

The Apparatus Devised for the Haulage of Heated Tarvia and Uniformly Applying It to Highway Surfaces, Used by the Barrett Manufacturing Company.

A COMBINATION service of motor trucks and animal wagons has been developed by the Barrett Manufacturing Company, which has plants located in different parts of the country, that is maintained to be materially economical, and the policy of the corporation is to utilize this equipment wherever it has a station. In keeping with this the company has installed machines in several centres of distribution and is developing its equipment along lines that were practically perfected at Boston.

The company has a business that is general throughout the United States and Canada, and primarily it is manufacturing products from coal tar. Other forms of bitumen are utilized, however. The concern produces building material in large quantities, including roofing, compounds for highway construction, as well as products that are widely used for disinfecting, cleaning, etc. The road material is in three grades or qualities, and it is made of a base of coal tar that is combined with several other ingredients, and is produced by a chemical formula. By refining the compound is brought to a condition where certain necessary qualities are obtained, and there are three grades, one of which has such fluidity that it may be worked when cold, but the other two can only be worked when heated.



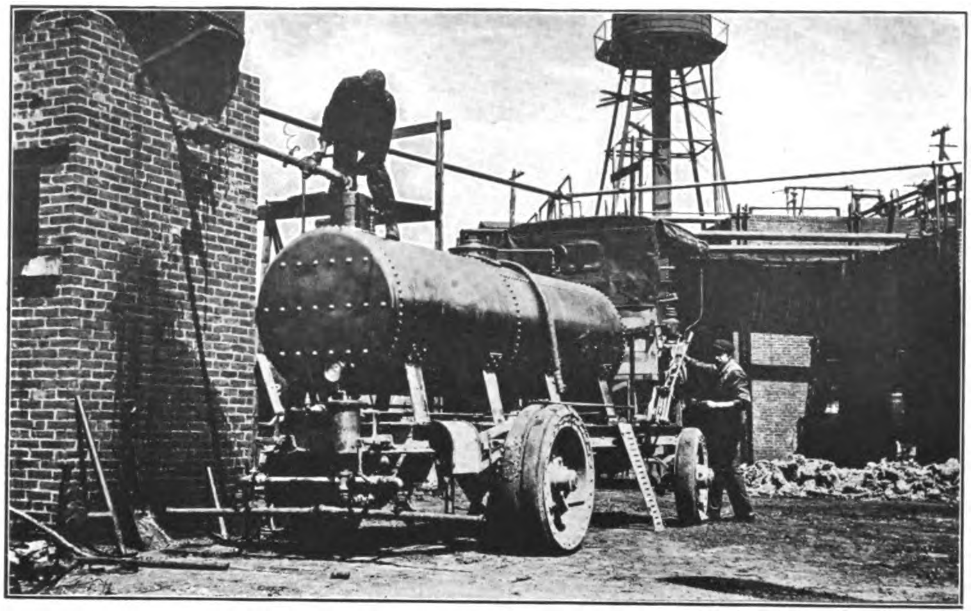
Alco 6.5-Ton Chassis Fitted with 1200-Gallon Tank Used for the Distribution of Heated Tarvia in Road Construction by the Barrett Manufacturing Company, Boston, Mass.

The company has manufactured these coal tar road construction materials for a number of years and they have been used more generally each succeeding year. The corporation maintains refineries in more than a score of cities and different parts of this country and Canada, and has a London, Eng., branch. At these refineries the material is prepared and it is shipped in either tank cars or barrels, or it is carried in tank wagons or trucks to the place where the construction is in progress. There are several methods of working the compounds practically.

With the fluid form, which is the easiest worked, this may be taken from the tank cars or the barrels and distributed by tank wagons, but there is, unless a stated pressure is maintained in the tank, a loss of "head," so that while there will be a maximum spread on the surface from the gravity pressure when the tank is full, this pressure will be gradually reduced during distribution, and the application will be heavier as the quantity in the tank is decreased, but will not cover as wide an area. This has been the experience at all times when distribution of a liquid is made from a tank without pressure, but with water, when used for dust suppression, this condition is not of consequence. When it is necessary to make a reasonably even spread of material the common tank has never been a satisfactory apparatus.

As may be assumed, it is important that any application of tar to a road surface shall be even, and this cannot be secured through manual handling, no matter how great care is given. For this reason a fluid compound should be applied from a tank under pressure. Such a treatment of a highway, however, cannot be regarded as permanent, and it will best serve as a dust suppressor. For this reason a heavier material is necessary, and the desired quality cannot be obtained with any material degree of fluidity, for the compound must solidify when cold. The second grade of material is such that it must be heated, and when this is shipped it must be in tank cars that are fitted with coils of pipe that may be connected with a steam boiler and the contents liquified so they may be drawn off, or it may be shipped in barrels.

After heating in the tank cars the material can be transported a short distance, or under such circumstances that it will not greatly cool, and applied, but this necessitates the use of tank wagons. If shipped in barrels, the containers may be destroyed and the contents melted in large kettles at the roadside, but this necessitates hand application, which is not as even and is far from economical. The third grade of material is



Loading a Tank Wagon with Hot Tarvia at the Works at Everett, Mass., for Transportation to Construction Work.

even heavier and can only be liquified by heat, and its distribution must be by the same means.

With relation to road construction, it may be stated that the unit of work is square yard of surface area, and in the building of tarred highways estimates are made of the volume of material in cubic yards of stone and gallons of tar, and the specifications require that the tar be evenly applied. If the treatment is not uniform the surfacing will not endure under traffic, and if there is a shortage of tar through absence of uniformity, this must be made up, and the cost is additional. As the success of the construction depends upon the quantity as well as the quality of the tar, and economy prompts equality of distribution, it will be seen that equipment for applying the material is of prime importance.

As a matter of business it was desirable for the engineers of the Barrett company to have the work performed so that the best results would follow. In some instances the company supplies the material to contractors and the municipal and state departments, and in others the company, within reasonable distance of the refineries, makes the applications of tar with its own equipment. The company makes recommendations for applications, and, when doing the work, follows these carefully. As the tar can be applied to the road work only when the stone is dry, it is necessary to work rapidly at times, and to take advantage of every opportunity for making the treatments. The company has always delivered the tarvia within a reasonable distance of its refineries. One of the first constructions adapted for use with animal trucks was metal tanks of from 800 to 1000 gallons capacity, which were utilized at the New England branch at Boston. These were filled at the refinery at Everett and were hauled to the construction, the limit being about 20 miles. The tanks were filled with the liquified tar, heated to something like 300 degrees, and on arrival it was possible to apply this without heating. But as application need be uniform a pressure was required. This was supplied by connecting the tank with the boiler of a steam roller, and with the roller towing the truck at a speed of four miles an hour the tar was forced in a spray through a header attached to a hose from the outlet of the tank.

Using a steam pressure of about 100 pounds to the square inch it was possible to sufficiently heat the tar, even if it had been cooled, and it could be forced from the hose so as to insure a desired degree of penetration. This worked out well, but there was the limitation of the horses. The next step was the installation of a tank on a motor truck, and while it was necessary to use this as the horse trucks were used, there was a very much improved radius of movement. With horses the time required for transportation was large, although application could be quickly made, and where the work was of considerable proportions it was necessary to use several trucks, even within short distances. Using the motor trucks the saving was principally in

Applying the Hot Tarvia with a Hose from the Tank Under 100 Pounds Steam Pressure, Supplied by the Boiler of a Road Roller.

transportation, for the machines could be driven a long distance in comparatively short time, and while it was practical to drive even 50 miles from the refinery, with the need of the steam pressure, and the haulage by the roller there was practically no saving in time necessary for application.

Experiments were made in reduction of temperature of the tar during transportation, and it was found that if heated to 300 degrees at the refinery it could be hauled from four to five hours and still have sufficient fluidity to be applied. In other words, the time of the steam roller and its crew could be dispensed with, provided there was a means for forcing the tar from the tank under pressure. Not only this, the tank capacity could be increased to the maximum of the truck, and this was a further economy as compared with horses.

A tar spraying apparatus, built by an English firm, was imported by the company, but it was not adapted for use in construction, many of the parts being so light as to break when used in construction, and as these could not be renewed save by orders that required a month's time to fill it was not regarded as economical, though it would have no doubt been serviceable in surfacing roads that were completed and were smooth, such as it was designed for by the maker. To prevent delays special equipment was necessary, and with the area of distribution considerably extended the need of reliable apparatus was evident.

The first truck used was equipped with a tank and was used as were the wagons, with the steam roller, but the second machine was considerably improved. This was provided with a power pump, driven from the transmission shaft, and with this it was practical to force the 1000 gallons in the tank through two headers at the rear of the chassis in 75 minutes. By driving the truck a mile along one side of a roadway and returning, a surface 14 feet wide could be tarred in an hour and a quarter, this application being uniform in every respect, and the distribution covering a precise area. As it was possible to deliver tarvia heated at the works at a distance of 50 miles at a temperature that it could be worked, and applied to the approval of the engineers, it will be seen that the equipment was in itself a decided success.

A careful record was kept of the work performed and it was found that while the economy of horses for short hauls, using the steam roller method of distribution, was evident, for any distance from six miles to 25 there was a large measure of saving with the truck apparatus. Beyond 25 miles, however, there is a belief that the cheaper transportation is by tank car, leaving the application to the purchaser of the material. This is, of course, from the viewpoint of the company, and there is no allowance made for the better application and the standard quality of the work.

The first season the company had two trucks in service, one of them a three-ton and having an ordinary tank, and this was supplemented by a five-ton truck with a regulation tank equipment. Last year the company installed two more at the Everett plant and purchased others for use at New York and Montreal, all of these being fitted with power pumps. This year the number has been increased and these have been considerably improved. In fact the latest machine may be regarded as standard equipment.

The latest apparatus consists of a 6.5-ton Alco chassis, on which is installed a 1200-gallon tank that will stand several hundred pounds pressure. This tank has a large manhole at the top, where it may be filled by gravity from the large tanks at the refinery. At the rear of this tank is the outlet, and this is connected with a system of pipes, in yoke form that carry at either end of the yoke a header that may be adjusted to spray at any angle, and which may be set at any desired height above the road surface. Normally the spray is applied transversely across the path of the truck, covering an area seven feet wide, but this can be varied as desired. The tank is fitted with coils of pipe that may be connected with any steam plant so that in the event of the contents cooling it may be liquified.

Sand Spreading Wagon, Used for the Application of a Top Dressing on Oiled or Tarred Street by the Public Works Department, Providence, R. I.

On the driving shaft, forward of the gearset case, is a sprocket, and this may be connected by a sliding clutch so as to turn with the shaft by linkage with a hand lever that rises within convenient reach of the driver. By a chain this sprocket is coupled with a shaft above the chassis frame that parallels the driving shaft and ends at a rotary pump located on the chassis close to the rear end of the tank. At will the pump may be operated by movement of the hand lever, and

the contents of the tank forced through the system of pipes at a pressure of 100 pounds, and this pressure may be varied as desired. In the event of necessity the pump may be reversed and the tank filled through the pump, the pumpage being approximately 1000 gallons an hour. At the rear end of the tank are three try cocks, by which the height of the contents may be learned. The pumping plant is controlled by pedals, so that the application can be made as required, and in the event of the flow being stopped and the pump operated the tar will by-pass into the tank and there will be no loss of material.

Very accurate record is kept of the operation of the machines, and taking a five-ton truck, the expense, including gasoline, oil, grease, repairs, tires, cleaning, wages, depreciation, interest, taxes and fire and liability insurance is carefully itemized. A year's work for this truck shows the following figures:

Average miles a day	41.14
Ton-miles a day	100.50
Gasoline, miles a gallon	2.46
Total cost a mile	$0.316
Cost a ton-mile	0.130

Taking this as a basis of the work, it is found that there is but little difference in the expense of each vehicle, and the above may be said to be fairly representative of the cost of the trucks.

FEDERAL IN CANADA.

Makes Long Cross Country Trip Over Poor Roads Without Need for Adjustment.

A Federal truck, made by the Federal Motor Truck Company, Detroit, recently made a trip from Winnipeg to Regina, Saskatchewan, Canada, a distance of 464 miles, in 42 hours of running time, with a load of 7500 pounds. The cargo consisted of a load of bed springs and mattresses from the Alaska Bedding Company of Winnipeg to the Alaska Bedding Company of Regina.

Four days were consumed in the run, the average mileage being 116 miles. The road conditions were extremely bad during most of the trip, a great many sand hills and sandy stretches being encountered, especially around Carberry. From Moosomin to Greenfell there are practically no roads, so that the truck had to pass through trails and cross sloughs where planks were laid to keep the vehicle practically free of water. It was not found necessary either to make adjustments during or after the trip.

ORDERS WHITE TAXICABS.

Chicago Concern Influenced by Successful Installations in Other Sections of the Country.

Closely following a sale of 63 White taxicabs to the Taxicab Company of California, the White Company, Cleveland, O., maker of White pleasure and commercial vehicles, reports another large sale of 50 machines to the Owen H. Fay Livery Company of Chicago, one of the largest cab operating concerns in that city. The order includes 48 taxicabs and two 40 horsepower touring cars.

The California company operated 19 White cabs for almost two years before filling out its fleet to 82. The Chicago company, however, has not used White cabs, but has noted their work in the service of other concerns and was largely influenced by the decision of several large operators to employ White machines.

NEW YORK'S TAXICAB ORDINANCE.

Operating Companies Seeking Various Means to Avoid Complying with Its Provisions.

The board of aldermen of New York City recently enacted an ordinance that establishes a new rate of taxicab fares and abolishes the private control of cab stands by hotels, cafes, etc. Some of the largest companies, chief among which is the Yellow Taxicab Company, have sought to enjoin the city from enforcing the provisions of the ordinance, on the ground that enforcement would mean practically confiscation of their property because of lessening their earnings through reduction of the fares.

Failing in this a restraining order was sought by taximeter manufacturers, because it was claimed to be impossible to provide the class of indicating instruments required by the ordinance from lack of manufacturing facilities, for a considerable period of time. Next, some of the protesting companies founded stands on private property and in this manner evaded the ordinance because business is not solicited on the public streets. Several large companies have complied with the ordinance, which was advocated by many who owned a few machines and who assumed they would profit by the reduced fare. Meantime the city authorities are seeking means for bringing all taxicabs within the provisions of the ordinance, and the resisting companies are fortifying themselves so far as they can and are charging the old rates.

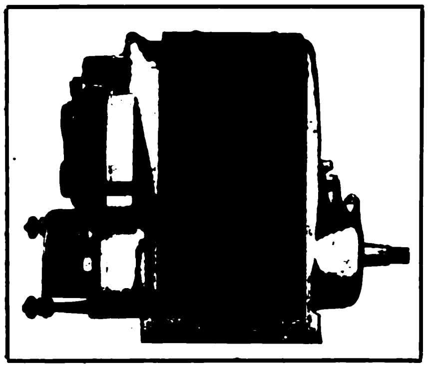
George M. Winslow, a piano dealer of Waukesha, Wis., is a highly pleased convert to the sound theory that motor delivery is distinctly worth exploiting. Since he purchased a 1500-pound KisselKar truck, made by the Kissel Motor Car Company, Hartford, Wis., he has kept that fact persistently featured in his local newspaper advertisements with what he declares to be highly satisfactory results. He has found that people appreciate the superior reliability and speed of motor delivery and make their purchases from merchants employing it.

The contract for transferring the mail below 42nd street in New York City, which was awarded to the Postal Service Transfer, Inc., May 2, went into effect Sept. 1. One hundred motor trucks have replaced the horse wagons previously used in this work.

FEATURES OF NEW MODEL P REMY MAGNETO.

ANNOUNCEMENT is made by the Remy Electric Company, Anderson, Ind., well known maker of ignition and lighting instruments, of a new high-tension magneto which is to be known as the model P. The new instrument is of the wire wound armature type, producing a dynamic spark of great intensity with a distinct flame characteristic. The design is in no way radical or freakish, embodying as it does standard proven practise, and was carefully developed by the Remy engineers. Refinements of design and improvements for greater efficiency have been incorporated wherever possible, these being based on the 15 years' experience in the manufacture of ignition apparatus.

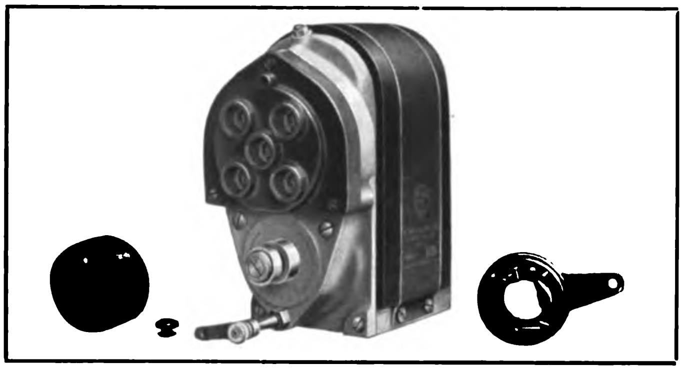
The new magneto is held to be absolutely water and dust proof. The end bearing plates are carefully and accurately machined to fit the magnets and the distributor is also similarly machined to fit the gear-case. A special packing is utilized in all joints to exclude water, oil, dust, etc. The distributor terminals are of water proof design and at the same time provide a reliable method of securing the high-tension cables. The circuit breaker is thoroughly protected by a cover of Bakelite, a heat resisting material of high dielectric strength, which is held to be decidedly superior to hard rubber or composition material, it being pointed out by the company that it is stronger, tougher and will not warp or crack, when exposed to heat, being non-hygroscopic.



New Model P Remy Magneto.

The armature heads are of special bronze and the drive shaft is of a high grade steel cast into the armature head, providing a very rugged construction. The coupling end of the shaft is tapered, keywayed and threaded to S. A. E. standards. The armature winding is of cotton covered, enamelled wire, heavily impregnated with Bakelite, rendering it impervious to heat and moisture. The armature shaft revolves on special magneto type ball bearings protected from foreign elements by felt washers.

The circuit breaker of the new magneto has been improved over previous designs and is held to be exceedingly fast as well as positive in its action. It may readily be removed by the hands for inspection and its simplicity is apparent by the accompanying illustration showing the mechanism disassembled. It is claimed by the company that adjustments are unnecessary under normal operating conditions. The circuit breaker is constructed of a high grade chrome nickel steel, hardened in pyrometer equipped furnaces, ground to size and tested accurately for synchronism and degree of hardness. The timing lever may be attached to either side of the magneto as the circuit breaker and its housing are reversible. The timing range is ample, 35 degrees, and by carefully proportioning the magneto and coil it is held that practically the same intensity of spark is obtained at full retard as at the maximum advance.

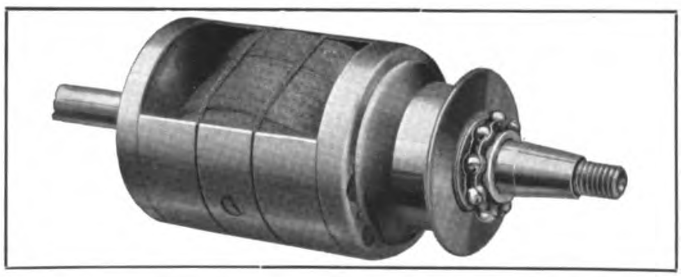


Circuit Breaker and Housing Dismantled to Show Simplicity of Construction.

The terminals of the spark plug cables are located in the face of the Bakelite distributor and are water proof as previously pointed out. Provision is made for easy timing of the instrument, an ingenious device known as a timing button being incorporated in the distributor. This permits bringing the circuit breaker into its proper position, as well as locating the proper terminal of the magneto. It also eliminates opportunity of connecting the wrong leads, a feature which will appeal to those who care for their own cars.

The distributor gears are accurately cut, 24 pitch teeth being utilized. The large gear actuating the distributor proper is of bronze, while the smaller member on the armature shaft is of cloth and steel, a design insuring quiet operation. The distributor brush holder is of Bakelite and is rigidly mounted upon the brass distributor.

The magnets are constructed from a high grade tungsten steel especially heat treated and hardened. The condenser and case form the top plate or cover over the armature, and the condenser is well protected by being imbedded in a heat solidifying compound. In addition to being made moisture proof in this manner a Bakelite cover is utilized. A new coil is employed with the magneto, having an integral dash switch, and a locking device is incorporated.



Heat and Moisture Proof Armature Revolving on Special Type of Ball Bearings.

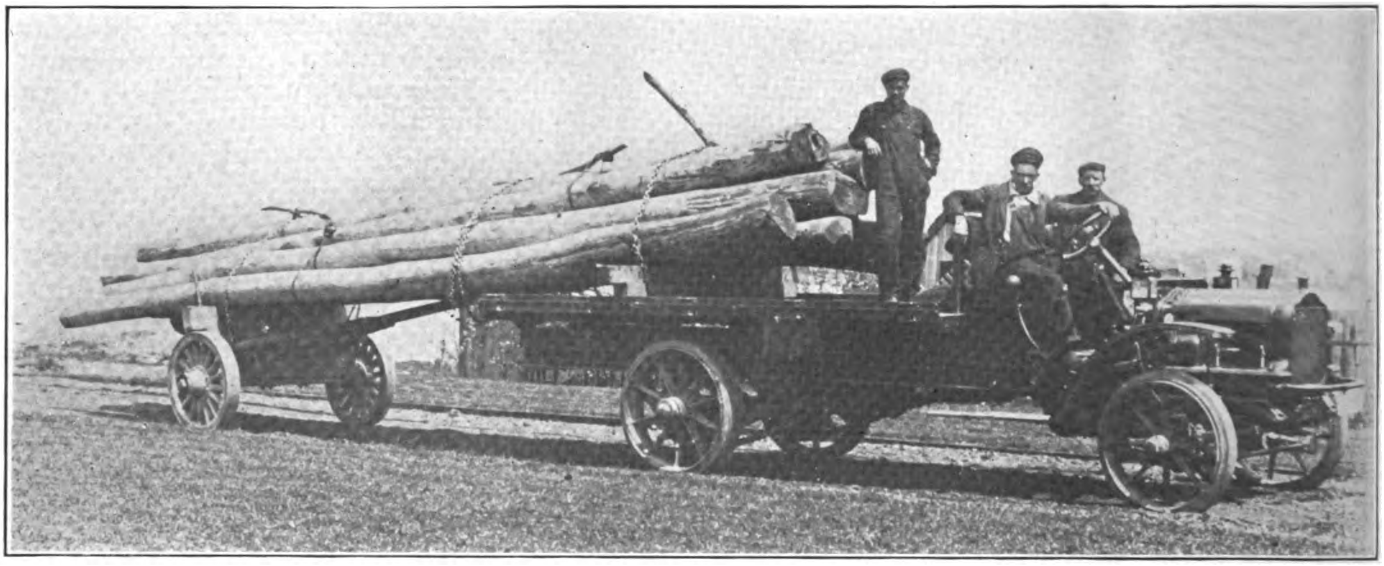
WHITE TRUCK IN ELECTRIC RAILWAY SERVICE.

Utilized as an Emergency Wagon Its Work Is Greatly Varied---Annual Maintenance Figures Show Total Mileage of 7953 at an Expense of 27.73 Cents a Mile.

OPERATING a three-ton White truck, made by the White Company, Cleveland, O., an average of 21.75 miles a day for one year at a cost of 27.73 cents a mile, the Union Street Railway Company of New Bedford, Mass., through its general superintendent, Elton S. Wilde, says that, "considering the various kinds of work this truck has performed, we feel satisfied with our investment." An investigation of the installation reveals the fact that the machine has been given a severe test, although there is no evidence that it has been overloaded or subjected to undue stresses.

New Bedford is situated on an arm of Buzzards Bay and might be regarded as a terminal city for several trolley lines extending into the interior, southwestern Massachusetts being plentifully supplied with electric railways of this type. The Union Street Railway Company operates the lines within the city proper from New York, while the remainder comes over the railroad from Boston. Of course, the wharves are located at sea level and the railroad freight yards are not far distant. The residential portion is built on a hill, the topography of the city being such that it is long and narrow, with the length running along the top of the hill or on its sides parallel thereto. It is less than a mile from the lowest point to the highest, and the grade is not steep at any point. The street railway serves the business and factory districts, as well as the residential and suburban sections.

The truck was purchased of the Auto Selling & Supply Company, John S. Coy, manager, Pleasant and Spring streets, local agent for the White Company. It was placed in service March 1, 1912, and the figures submitted herewith were compiled to Feb. 28, 1913. It was secured primarily for hauling rails, ties, poles,



White Three-Ton Truck in Service with Union Street Railway Company, New Bedford, Mass., Hauling Poles.

and those leading from New Bedford to a number of so-called suburbs, among which may be included Fairhaven and Onset. It also operates the connecting line between New Bedford and Fall River.

As is true of most cities of its size (96,000 in 1910), similarly situated, there is demand for trolley service to numerous seaside resorts in the immediate vicinity, and in addition the company is interested to a large extent in the development of an outing park, known as Lincoln Park, about half-way between New Bedford and Fall River. During the summer months, a theatre and other diversions are maintained at this point in an effort to attract larger crowds than otherwise would be the case, and from time to time special events are held there, these including a fair. This comment is of importance, as will be indicated later.

Some of the freight reaches New Bedford by boat wires, etc., in construction and maintenance work on the different lines of the company. Much of this material comes into New Bedford either over the steam railroad or by boat. The yard of the company is located at Purchase and Weld streets, on the so-called lower level. It follows that the truck is called upon to traverse the hill when communicating with the lines to the westward, and cross the bridge into Fairhaven when working on the suburban lines to the east and north on that side of the river.

For the most part the streets of New Bedford are well paved, the surface being asphalt, bitulithic or macadam, except in a very few instances. There are no better roads in the country than in Fairhaven, these having been built under the street superintendency of the late H. H. Rogers, of Standard Oil fame, who contributed annually much more than his salary as super-

intendent to build up a road system second to none. Many of the country roads are state highways, the surface being oiled macadam. It goes without saying, therefore, that the road conditions under which this machine has been operated are well nigh ideal.

It has been stated that the truck was purchased primarily for hauling material in construction and maintenance work. When Mr. Wilde was asked to state what kind of work it had been engaged in, he replied: "It would be somewhat less difficult if you were to ask me what sort of work it has not been called upon to do." It is an emergency wagon in every sense of the word, and as such is in commission 24 hours of the day. At times it is busy in the service for which it was intended. Sometimes it is in charge of one man. At other times it is hurrying over the road at its best speed with 15 or 18 section hands and a load of poles and wires to mend a break in the line. It has served as a tower wagon. It has transported exhibits, etc., in promoting Lincoln Park. When not otherwise employed, it carts away the ashes that accumulate at the power station. Sometimes it carries a capacity load, and at others it is worked light. It is at the beck and call of the entire system. It goes wherever it is needed, at all hours of the day or night, week days and Sundays. Therein lies the severity of its test, rather than in poor roads or other conditions which would be regarded as severe in other industries.

Mr. Wilde has an admirable bookkeeping system with respect to this machine. MOTOR TRUCK is not interested in presenting figures which shall reveal the business of an individual concern, although its representatives often have opportunity to go over the books of companies employing mechanical transports. It will not be amiss to state in this connection that at no time has the writer seen a statement of maintenance costs so well tabulated as that presented by Mr. Wilde for inspection. For instance, on one occasion this White truck was called upon to tow another machine to a local garage. Mr. Wilde is able to tell exactly what that piece of work cost his company. This statement is made because of its bearing upon the figures presented herein. There can be no disputing such evidence.

During the year, the truck was operated 7953 miles at a total cost of $2205.09, or at the rate of 27.73 cents a mile. This total represents the maintenance account alone and does not include any charge for driver or crew. It will be noted, from the accompanying table, that some 15.23 cents of this is made up in overhead, this including depreciation at 15 per cent., interest on the investment at five per cent. and insurance. The depreciation is figured on the chassis, minus the tires. A sinking fund for annual overhaul and repairs, amounting to $400 a year, has been established, but it would appear from the table that, including all that could by any means be charged to this account, this fund was lowered but $224.27 during the year, so that there was a balance of $175.63 to be carried forward March 1.

The subject of tires always is of interest. This has proven the most troublesome of all with the Union Street Railway Company, despite the excellent character of roads over which the vehicle has been operated. It may be stated in explanation of the situation that the company and the tire maker have had some little controversy over the matter of adjustment. For this reason, Mr. Wilde does not feel justified in taking up the subject in detail. His figures show a tire cost of 4.87 cents a mile. The machine is shod with solid rubber all around—dual equipment on the rear wheels.

Union Street Railway Company's White Truck Engaged in Transporting Rails in Construction Work.

In considering the matter of gasoline, it must be remembered that the price was somewhat different in 1912, these figures being up to and including Feb. 28, 1913. The fuel cost of 2.24 cents a mile works out at a satisfactory consumption when reduced to miles a gallon, although the cost figures for the present year undoubtedly will be somewhat higher. In this connection, it may be stated that Mr. Wilde has compared the fuel cost with such figures as he has secured respecting trucks of other makes, and feels well satisfied.

The item "Top" needs explanation. The machine was purchased without a top over the driver's seat, and it was decided later to add this comfort. The expense was charged to the maintenance account, although perhaps there might be a just claim against such procedure. It may be added here that the machine was out of commission practically two days during the year, on account of tire trouble. It also was laid up for painting.

Annual Maintenance Account of White Three-Ton Truck in Service with Union Street Railway Company, New Bedford, Mass.*

	Mile	Total
Gasoline	$0.0224	$178.15
Grease	0.0048	38.17
Oil	0.138	109.75
Supplies	0.0029	23.06
Labor, painting, etc.	0.0282	224.27
Top	0.0042	33.40
Tires	0.0487	387.31
Overhead	0.1523	1210.98
Totals	$0.2773	$2205.09

*Cost a mile taken from company's books; totals carried out on basis of 7953 miles actually travelled.

It might be suggested as a little strange that a concern engaged in the production of electricity should utilize a gasoline truck. It must be remembered, of course, that the voltage of the current used for street railway purposes is somewhat higher than that utilized for lighting, etc., but it would be possible to employ a transformer, so that the cost of current would be governed solely by the matter of production expense. Basing an estimate on the prevailing price of current in New Bedford, 3.5 cents a kilowatt-hour, and the total mileage for the year, Mr. Wilde believes an electric truck could be operated just as economically as this gasoline machine.

In some respects, an electric vehicle would prove quite as efficient, in Mr. Wilde's opinion. He cites the use as a tower wagon. When the men are at work repairing a break in the wires it often becomes necessary, or at least more convenient, to move the truck a short distance—less than a foot. When it is a matter of cranking the engine and manoeuvring into position the workmen prefer to "stretch" a point rather than move the truck. With an electric machine, Mr. Wilde believes it would be easier to make the required change of position.

At the other hand, while the total mileage for the year, 7953, divided by 365 days, the number of days in which the truck was on duty, shows an average daily mileage of 21.75, this statement does not accurately describe the situation. The manner in which the truck has been worked precludes the possibility of arriving at an average daily mileage as with machines utilized in other lines of business. One day it may travel 35 or 40 miles, while the next it may be kept busy on work which calls for considerable waiting and comparatively small mileage, and at all times it is available night and day. The special service required had its effect in arriving at the decision to purchase a gasoline vehicle.

Another point that will be raised is the comparative expense of horses. Unfortunately, it is impossible to give such figures. Mr. Wilde explains that it would be impracticable to use horses, for the reason that the work is so variable. On some jobs only one horse would be required, while with others perhaps it would need three or four. The truck is available night and day, and weather conditions have no effect upon its efficiency. It is as ready to respond at night after a hard day's work as it would be if it had been "resting" for hours. Extreme heat, or snow and ice, make no difference with its availability.

In many respects this installation is of particular interest. The accompanying tabulation is especially valuable for the reasons given herein. It ought to afford a splendid opportunity for the prospective purchaser to gain reliable information as to what it costs to maintain motor business vehicles, although local conditions will have to be considered. "We are pleased to endorse the White truck," says Mr. Wilde, and he is satisfied that it is an economical proposition.

SAURER TRUCK OPERATING COSTS.

Interesting Figures for Six Months Submitted by Brooklyn Chemical Concern.

The Crescent Chemical Manufacturing Company, Brooklyn, N. Y., reports some very interesting operating costs, showing what it has done for some time past with a Saurer truck, made by the International Motor Company, New York City. It states that during a period of six months it operated the vehicle 199 days, a distance of 8879 miles, or an average of 44.6 miles a day, at a cost of 12 cents a ton-mile. The account rendered by the concern of its operation of the truck was as follows:

Month	Mileage	Days in Operation	Maximum Mileage	Minimum Mileage	Load Out Lbs.
March	1120	24	75	27	404,250
April	1070	23	72	33	470,250
May	734	15	72	12	264,000
June	1074	25	57	27	445,500
July	1274	26	74	29	486,750
August	1147	26	74	20	437,250
September	826	19	67	24	338,250
October	919	25	66	16	387,750
November	185	4	65	32	66,000
December	530	12	61	13	198,000
Total	8879	199	..	..	3,498,000
Estimated load incoming, 70 per cent					2,448,600
Total haulage					5,946,600

Expenses.

Chauffeur	$831.57
Helpers	903.50
Garage rental	230.00
2015 gallons gasoline	342.55
Oils and other supplies	213.12
10 months' insurance	318.75
10 months' interest	250.00
10 months' amortization	416.60
Tire repairs	532.74
General repairs	355.16
Total charges	$4393.99

Or $22.08 a day, 49.5 cents a mile, $7.47 a ton and about 12 cents a ton-mile.

"These figures give as accurately as possible the total cost of delivery," says the company. "There have, however, in the meantime been accumulated the following reserve funds:

For amortization	$416.60
For tire replacement, $532.74, of which at least $150 remains in the present tires	150.00
For general repairs, $355.16, of which $174.93 has not been used up	174.93
Total reserve	$741.53

"In the total cost of operation is included the item of $903.50 for helpers for loading and unloading, which amounts to 20.15 per cent. of the total charges. The actual operation of the truck, not included in the helper's charges, amounts therefore to $18.05 a day, 39.33 cents a mile, $1.17 a ton, 9.5 cents a ton-mile."

LEGISLATION TO LIMIT WEIGHT OF TRUCKS.

THE New York State Automobile Association, an organization composed of American Automobile Association clubs, and representing a very small proportion of the owners of automobiles in New York, has announced that it will exert its influence in securing the passage by the legislature at the 1914 session of legislation that will "preserve the highways." Very recently the secretary of the association, Robert S. Ross, stated that it was the intention of the body to take an active part in legislation, and that it was the purpose of those directing its activities to attempt to limit the weight of the truck and the load to three tons, and to require tires to be of a width proportionate to the maximum weight to be carried.

Mr. Ross is quoted as saying: "Under present conditions it looks as if the roads or the motor trucks would have to go. In all probability the motor trucks will force the construction of more permanent types of roads, but until that time comes, motorists generally feel the macadam roads should be protected."

It will be noted that, if the statements correctly reflect the purposes of the pleasure car owners represented by the association, the intention is to ask that the weight of the vehicle and load be limited to 6000 pounds, and that these be fitted with tires of adequate width. To take these statements literally it will be understood that the association proposes to prevent the use of freight machines that are much heavier than the heaviest types of passenger cars. This is not an extravagant assertion, for many of the large automobiles will weigh close to 4000 pounds, and with the load of from five to seven passengers the weight will increase as much as 1000 pounds additional, leaving but a margin of 1000 pounds between the maximum weight of the touring car and the freight motor wagon.

But these machines can be and are very frequently driven far in excess of the limits prescribed by law, and naturally the greatest speed is made over the best sections of highway. The maximum speed of the well built and well designed light motor delivery wagon is from 14 to 16 miles an hour; the maximum of the three-ton truck is 12 miles, and of the five-ton truck from nine to 10 miles when driven light, and somewhat less than these figures when loaded.

The best authorities on road construction are united in the opinion that the motor vehicle driven up to 15 miles an hour does not cause more wear of the surface of a road than does an animal cart or wagon, and it will be admitted that the average speed of motor trucks is considerably less than this, a fact that is especially true of the larger machines.

There are some facts relative to road construction that may not be apparent to the average citizen, and one of these is that a water bound macadam road will not endure under combined horse and motor vehicle traffic. A tar macadam will last for a long time under motor driven traffic alone, and a gravel road will stand combined horse and motor travel better than macadam, because the roadbed is consolidated by the wagons and machines passing on it.

The proportion of automobiles to trucks in New York is about 10 to 1, and a considerable number of the service wagons are electrics, which have a maximum speed of from seven to 12 miles. With comparatively few exceptions these are worked in the cities. Probably 10 per cent. would be a fair statement of the number used constantly on the state highways. Assume this number to be 1500, and the average speed 12 miles, and place against this the 100,000 or more machines that are largely used on the roads, driven at high speed as often as the drivers care to take a chance, and contrast the possibilities of wear of the highways from either source.

Before the use of automobiles became general the owners of horses maintained they were the only ones who had rights in the streets and roads. It was chiefly this opposition to automobiles that caused taxation of the machines. The motorists would have been driven from the roads had the majority been successful in its opposition to the automobile. The nonsensical argument was made that the automobile was destructive of highways and its use was accompanied by all sorts of results, some of them menaces to health as well as to persons and property.

Now the automobilists, or some of them, have assumed identically the same attitude as did the owners of horses, and in some instances those who owned no vehicles, and maintain that the motor trucks should be limited to proportions so small that their usefulness would be nullified. But there is another aspect as well. If such a law should be enacted those who now own machines that would be prohibited their use would necessarily be deprived of their property, and as these have been purchased without limitation or restriction as to size or weight, there would necessarily be recompense made to them. In other words, the law could not be made retroactive without providing compensation for those who were prevented using the trucks.

Then arises the subject of tires. Just what sizes would be necessary or desirable on vehicles of differing weights have never been determined conclusively. Tire size has been largely a detail of design and no standards have ever been adopted by any body. The Society of Automobile Engineers has reached no conclusions as to tire width, and this is regarded as the authoritative body of the industry. There appears to be no necessity of specifying tire sizes for pleasure cars, such as are owned by those who have seemingly endeavored to eliminate the motor truck from the highways, and there does not seem to be a need for so constructing cars that they cannot be driven beyond a speed that is not destructive of the road surfacing. There is no doubt, however, that either proposition would be equally logical.

In Providence, R. I., there is agitation by some of the city council of a proposal to enact an ordinance

regulating the size and weight of the motor trucks used in the street. It would appear that the agitation is the outcome of the establishment of a couple of motor 'bus lines that have been operated from the centre of the city to Cranston and East Providence, and seemingly has emanated from the transportation company operating the trolley system, for the man who is active in promoting the proposition has been energetic in all public matters involving this company and its interests. It is maintained that the 'buses are too wide, when as a matter of fact they are narrower than the trolley cars. This appears to be the only objection to them.

The objection to some of the motor trucks used in the city streets is that some of them are too wide for the streets, and that they are too heavy and are destructive of the street surfacing. There are several seven-ton machines and a considerable number of five-ton trucks, but without exception these are fitted with bodies such as are used in other cities without protest. What is probably as asinine an argument as was ever stated, is that these machines are an inconvenience or source of discomfort to those having homes or offices in the streets.

In the business section of Providence there are few wide streets, for the highways were laid out in some instances more than two centuries ago, and a considerable number are 30 feet wide. The majority of these have been made one-way streets, however, and this congestion relieved. There are also numerous private ways between buildings and properties that are generally not more than 10 feet width, and while these are commonly used, the city has no jurisdiction over them. The proposed legislation, then, can only apply to highways that appear to be especially well regulated, and where the trucks are not generally used.

That there will be legislation purposing to increase the rate of taxation and limiting the weights of trucks used in the state introduced into the next session of the Massachusetts legislature there is not the slightest doubt. The chairman of the state highway commission, who has for two years been the leading sponsor of such measures, has been actively promoting a campaign of preparation since the adjournment of the legislative session. He has lost no opportunity to urge publicly that the owners of machines ought to pay a tax in addition to what they now pay, and that there is a limit to his mind as to the weight of the vehicle and load. The alleged weakness of a few bridges is the basis of his argument.

There is now no law that specifies the weight of a road vehicle of any kind, and until the chairman of the highway commission discovered the weakness of the bridges no danger was apprehended. There are laws, however, that require that roads be maintained passable and safe for such vehicles as are used upon them, and these are applied to all highways that are not under the jurisdiction of the state highway commission. The bridges in the state system, which is supposed to include the main thoroughfares of the commonwealth, are to be maintained by the commission, and if, in improving the roads and modernizing them, the commission has neglected to correspondingly improve the bridges, this neglect does not appear to be a valid reason for denying to the business men of the state and the adjoining states the right to use vehicles that will be efficient and economical.

In Massachusetts the same organizations that successfully opposed the passage of the bills at the last session of the legislature are awake to the possibilities of the activity of the commission, and the men active in them propose to know the attitude of every candidate for election. Those who are favorable to measures such as are favored by the commission will undoubtedly be opposed at the polls.

CARE OF BALL BEARINGS.

New Departure Manufacturing Company Issues Book of Valuable Suggestions.

Bearings in a motor car are most important components and the aim of the designer is to eliminate all friction and thereby avoid loss of power, a decided factor in the operation of a car. The repairman is often called upon to replace, adjust and clean ball bearings and the work requires a thorough knowledge of the construction and operation of the bearing if satisfactory results are to be obtained.

The New Departure Manufacturing Company, Bristol, Conn., maker of New Departure ball bearings, has compiled a manual which should be in the possession of every mechanic, repairman and operator of a commercial vehicle. It contains valuable suggestions for the best methods of removing and installing ball bearings, their lubrication and enclosure. The importance of proper maintenance, including cleaning, is defined, and a large number of illustrations make clear the points emphasized.

The book is written in a clear, concise manner, free from technical expressions, all explanations being couched in such simple language as to be easily understood. The brochure also contains description and dimension data on all types of bearings made by the company. The book will be sent free of charge by applying to Department M of the New Departure Manufacturing Company, Bristol, Conn.

The first of three KisselKar trucks made by the Kissel Motor Car Company, Hartford, Wis., purchased for freight and passenger traffic in the Ozark mountains of Missouri, has been delivered and placed in service. This machine operates between the towns of Houston and Cabool, a distance of 20 miles over difficult hills and unimproved roads. One round trip every day is made. Another truck will be used on the same run, so as to make two daily trips possible.

The White Company, Cleveland, O., in one week sold three orders that totalled 81 machines.

Municipal Service Equipment

CLEANS OUT CATCH BASINS.

Standard Truck Replaces Six Teams and 12 Men in This Class of Service.

The city officials of Pawtucket, R. I., or more properly speaking, Commissioner Gill of the department of public works, has devised a plan whereby a three-ton Standard truck, made by the Standard Motor Truck Company, Detroit, does the work of six-horse carts and 12 men in cleaning out the catch basins of the city. Not more than three men are required to work the truck and accomplish the same results.

The chassis does not differ materially from that regularly supplied by the maker. The body was built by the Monahan Vehicle Company, Providence, R. I., and embodies some of the ideas presented by Commissioner Gill. The entire outfit is designed to lower buckets into the sewer basin, there to be filled and then hoisted and dumped into the body of the vehicle. When the latter is filled, the machine is arranged to dump the entire load in 40 seconds, so that there is a material saving in time, as well as labor.

Directly back of the driver's seat is a two horsepower single-cylinder auxiliary engine, geared to a hoisting drum from which a cable is run through the centre of the crane and over pulleys on the arm. This engine draws its fuel supply from the same source as the regular motor which propels the truck, and the exhaust is arranged to communicate with the muffler. The water circulation is connected with the radiator, so that the two engines utilize practically the same system. At the front of the body is an hydraulic hoist for dumping the load, this comprising a long cylinder with a piston forced upward by oil from a gear pump, which is driven by a connection in the transmission case.

The mechanical details were worked out by James Nesbit, who is in charge of the motor apparatus utilized by the department of public works, and although the machine has been in service but a few weeks, the city is satisfied that its use will represent a very decided saving in expense, when compared with horses in this line of work.

ITS FIRST PUMPING ENGINE.

Fire Department in St. Paul, Minn., Has Highest Powered Machine in the State.

The city authorities in St. Paul, Minn., have purchased its first motor pumping engine of the Waterous Engine Works Company of that city. The machine was rated to deliver 700 gallons a minute, but in a two-hour test it delivered 840 gallons. The engine ran remarkably well, without any perceptible vibration. It is a six-cylinder machine and is said to develop 101 horsepower, making the machine the highest powered automobile fire engine in the state.

The vehicle has a 141-inch wheel base and is capable of making a speed of 50 miles an hour. It weighs 12,175 pounds with equipment and is arranged to carry 12 men, or, with the seats folded, 2000 feet of hose.

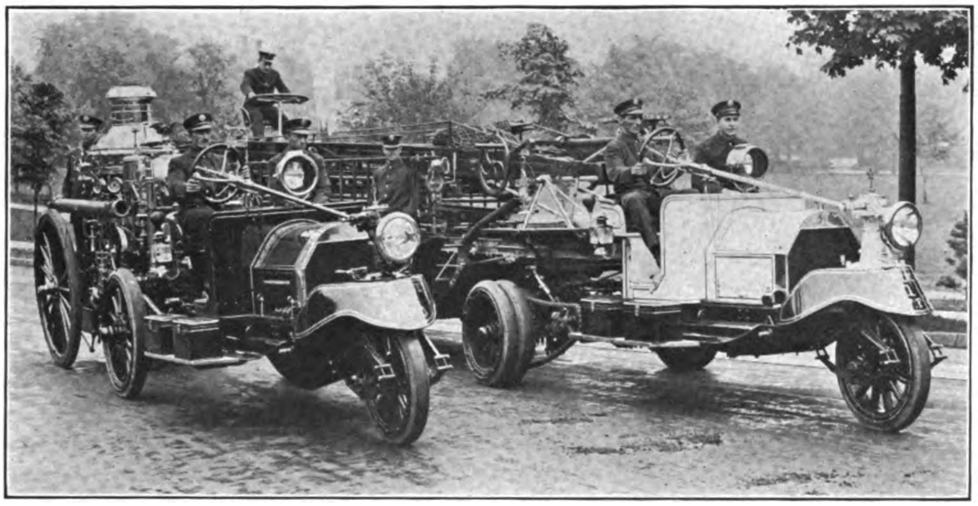
A Standard Three-Ton Chassis Fitted with Crane and Hoisting Engine, and Special Dumping Body for the Service of the Public Works Department, Pawtucket, R. I.

It has an electric motor starter and the machinery underneath is lighted by electricity. A stream from a 1.5-inch nozzle can be thrown to a height of 210 feet.

SAVING TWO DOLLARS A DAY.

Two Knox-Martin Tractors Will Soon Pay for Themselves in Mt. Vernon, N. Y.

One of the first Knox-Martin tractors made by the Knox Automobile Company, Springfield, Mass., was installed with the fire department in that city on a contract under the terms of which the city was to have a full year in which to test its economy and efficiency. The machine was attached to a water tower, which had proven too heavy for horses, and which, for this reason, was not kept in active service. Before the year was up the city had purchased the vehicle, it having been demonstrated in one fire alone that it was advisable to have the water tower in constant service and that the tractor was the proper means of propelling it. The city has now purchased a second vehicle of the same make, for use with one of its hook and ladder trucks.



Two Knox-Martin Tractors Utilized by Fire Department in Mt. Vernon, N. Y.

Herewith are presented two pieces of apparatus owned by the fire department in Mt. Vernon, N. Y., one a steam fire engine and the other a large hook and ladder truck. The latter has a double equipment of ladders and therefore presented a problem similar to Springfield's water tower, in that it was found exceedingly heavy for horses. The purchase of the two Knox-Martin tractors made necessary but very little rebuilding in order to make this portion of the department motor driven.

When the horses were employed the cost of the two pieces was figured at $72 a month. Motor driven, the expense has been less than $2 a month each. This leaves a balance of $68 a month, or a little better than $2 a day, in favor of the Knox-Martin tractors. And, of course, the limited cost of converting the two pieces was an item of no small consequence in considering the proposition in the first place.

HARTFORD'S SELF-PROPELLER.

Department Lays Claim to Having Oldest Apparatus of This Type in the Country.

Hartford, Conn., lays claim to the oldest piece of self-propelled fire apparatus in the country, the old "Blake seven" engine, a spare propeller which has been in service for 37 years. Officials of the fire department state that Hartford is the only city in the country which has had a self-propelled apparatus for so long a period. Other cities purchased propellers 40 years ago, but their use was abandoned at different times and the horse driven apparatus was used again until the introduction of the gasoline motor several years ago.

The "Blake seven" propeller was purchased by the city of Hartford in 1876, and was delivered in March of that year. It was manufactured at the Amoskeag Locomotive Works at Manchester, N. H. It was assigned to old engine company No. 7 and Augustus J. Loomis, now chief of the department, was the first engineer. The machine has always been satisfactory and its construction was so good that it was rebuilt only once, although minor repairs have been made at various times. The apparatus was transferred to company No. 4 in 1889. It became a spare engine on Aug. 22, 1901, and has been used in that capacity since that time.

The engine weighs between five and six tons and its pumping capacity is 700 gallons. It cost $5000. The city has had three steam propelled fire engines. The second machine was purchased second hand from Troy, N. Y., in 1879, and was later turned in in part payment for the machine now in use by company No. 4, which weighs 18,000 pounds and cost $7500. The propeller used by company No. 3 was purchased in 1889 at a cost of $7000 and was rebuilt in 1908, when a new boiler was installed. These two machines made it possible to retire "Blake seven" as an auxiliary machine.

BUYS FIFTEEN MACHINES.

Pittsburg Expends $100,000 of a $240,000 Bond Issue for Motorized Fire Department.

Pittsburg, Penn., has testified its faith in the automobile as a fire fighting machine by a number of new contracts just placed by the mayor and the director of the department of public supplies. These contracts involve an expenditure of $100,000. The new equipment and the successful bidders are as follows: Ten

combination chemical and hose wagons, $4500 each, American-La France Fire Engine Company, Elmira, N. Y.; one 75-foot aerial ladder truck, Knox-Martin tractor, $8550, Seagrave Company, Columbus, O.; one 85-foot aerial truck, Knox-Martin tractor, $8950, Seagrave Company; two tractors at $3250 each, and an automobile for chief engineer at $3550, to General Automobile Company.

The contracts are in accordance with a recently publically approved bond issue of $240,000 for automobile fire fighting apparatus. It is the policy of the present city administration to motorize the entire department and 50 per cent. of the fire equipment is now motor driven. The hilly topography of the city has been an important factor in inaugurating this policy and the result has been eminently satisfactory.

BATTERY DRIVEN FIRE ENGINE.

Maintenance Cost and Work Done During First Year of Service in New York City.

The only storage battery driven fire engine in New York City has been under test since April, 1912, in one of the up-town fire houses of Brooklyn. The annual maintenance expense for the first year was $388.74 as compared with $655.26 for a team of three horses which hauled the same machine previously.

In making the conversion to motor apparatus an engine was used that had been 10 years in service. A steel frame was built forward from the boiler and to this were mounted the driving gear and controlling apparatus, consisting of two Couple-Gear wheels, the usual steering devices and a controller similar to the equipment of a trolley car. An 80-cell storage battery completed the installation. Thus engine 217 became a straight electric machine as far as its motive power was concerned and remained a standard fire engine with respect to its pumping and fire fighting ability.

Before it went into service it was put through a series of speed trials in which it made a six-mile run through the city streets in 23 minutes, on one stretch developing a speed exceeding 20 miles an hour, while a hill nearly a mile in length was negotiated in 2.5 minutes. A recent report of its service showed the following:

From April 24, 1912, to April 24, 1913, the engine responded to 319 alarms. Some of the runs were short, others were more than a mile from the house, and although no record was kept to show actual distances, a mile run for each alarm is considered a fair average.

During this period there wasnot a single instance of damage to the electrical equipment, although street accidents and repairs to the mechanical parts necessitated 64 hours in the shops for replacements, a feature that is encountered in fire apparatus as well as in other kinds of engines and machines. More than 14 hours were spent at fires and approximately 230,000 gallons of water were pumped.

To reconstruct the engine cost the department $4000. As the apparatus now stands it has an estimated life of 20 years; so, figuring on a five per cent. basis, $200 a year is allowed for depreciation. Added to this is the cost of charging, the rate being six cents a kilowatt-hour; 1965 kilowatts were used in responding to a year's fires, so the current bill amounted to $117.90. Distilled water and sulphuric acid for new electrolyte, brushes for the motor and other repairs added $70.84 to the bill, bringing the total cost for the 12 months operation to $388.74.

Three fire engine horses, their harness, the hangers and the ceiling apparatus for dropping it over their backs costs the department $1059.75, and new animals and equipment are required every 10 years, making the item for depreciation $105.98. It costs $410.82 to feed three horses, horseshoeing costs $85.04 and veterinary service $21, and added to this is $32.42 for sundries, bringing the total cost to $655.26.

These figures show a difference of $266.52 between the two types of motive power, and while that difference is impressive enough, it is the feed item that shows most strikingly the real reason for the higher cost of maintaining a team of horses. It costs $410.82 to feed the animals, and the cost remains the same if they go to but one fire during the whole year or respond to an alarm every day. During this particular year the electric engine went to more than 300 fires and the bill for "feeding" the storage batteries was $117.90. Had there been but one fire the "feed" bill would have been in the neighborhood of 30 cents.

NEWS FROM VARIOUS CITIES.

Stewart for Water Department—The purchasing agent of Lowell, Mass., has selected a Stewart motor truck, made by the Stewart Motor Corporation, Buffalo, N. Y., to be used by the water department of that city. The machine cost $1725 with equipment.

New Bedford Adding Equipment—New Bedford, Mass., has decided to purchase two pumping engines of the Ahrens-Fox Fire Engine Company, Cincinnati, O., and the Robinson Fire Apparatus Company, St. Louis, Mo., and also a 30 horsepower Buick car, made by the Buick Motor Company, Flint, Mich., for the fire chief. A total special appropriation of $23,000 is made, $18,000 being for the pumping engines, $1900 for the chief's car, and $3500 for the extension of the fire alarm system.

Nine Miles in 17 Minutes—Joseph Johnson, fire commissioner of New York City, recently travelled from 189th street and Audubon avenue in a fire department automobile to Wooster and Centre streets in 17 minutes, going through the heavy traffic of Broadway in answer to a three-alarm fire call. The blaze was in the seven-story loft building at 179-183 Wooster street and did $100,000 damage before it was checked. Mr. Johnson was in a fire station on Washington Heights when the three alarms were sounded for the fire nine miles away. It is said to be the quickest time in which the distance ever has been made.

Truck in Mining Work—A large automobile truck soon to be added to the equipment of the United States bureau of mines at Pittsburg, Penn., will serve the same purpose as the railroad mine rescue cars. It will carry a small complement of men, oxygen helmets and rescue apparatus. While the railroad rescue cars are used for long runs, the motor truck is designed chiefly for use in territory within 100 miles of Pittsburg.

In the Market—The following cities are contemplating the purchase of motor apparatus: Georgetown, N. C.; Livingston, Mont.; Iowa City, Ia.; Clinton, Ia.; Ashland, Ore.; Anaheim, Cal.; Alameda, Cal.; Taft, Cal.; Weatherford, Tex.; Wichita Falls, Tex.; Richmond, Va.; Champaign, Ill.; Council Bluffs, Ia.; Winston-Salem, N. C.; Morristown, N. J.; Milford, N. H.; Grinnell, Ia.; Richmond, Ind.; Southbridge, Mass.; Albuquerque, N. M.; Findlay, O.; Pasadena, Cal.; Springfield, Mass.

FOREIGN TRUCK NOTES OF INTEREST

LEYLAND PUMPING ENGINE.

Interesting Machine Built in England for Fire Department in Shanghai, China.

An accompanying illustration presents a 55 horsepower pumping engine built by the Leyland Motors, Ltd., Leyland, Lancashire, England, for the fire department in Shanghai, China, and effectually dispels the illusion formerly created by published pictures of Chinese firemen rushing through the streets dragging a hand cart. This machine is thoroughly modern in every respect and reflects the progressiveness of the newer China.

The chassis is the standard gasoline model produced by this concern, although the company perhaps is quite as well known as a manufacturer of steam commercial vehicles, in which it has been engaged for many years. The motor is a four-cylinder unit, with bore of five inches and stroke of 6.5, being rated at 55 horsepower. This not only propels the machine, but drives the Rees-Roturbe rotary pump through a geared layshaft from the top of the transmission casing. The pump is of the four-stage centrifugal type and has provision for taking three lines of hose. It is rated at 450 gallons a minute.

Leyland Gasoline Pumping Engine, with Rated Capacity of 450 Gallons, for Service in Shanghai, China.

TWO MAUDSLAY CHASSIS.

Features to Which Special Attention Was Directed During the Olympia Show.

Among the exhibits at the recent motor truck show at Olympia, London, England, which called for special comment by the British motoring prints, were the chassis displayed by the Maudslay Motor Company, Ltd., Parkside, Coventry, England, well known as a manufacturer of both pleasure and commercial cars of merit. Two chassis were displayed, these being rated at three and five tons, respectively. An accompanying illustration presents the Maudslay char-a-banc, fitted to the lighter of these.

The three-ton chassis utilizes a four-cylinder motor rated at 30-40 horsepower, the bore being 4.5 inches and the stroke five. The cylinders are cast in pairs, the valves being overhead, actuated by a camshaft, worm driven from a vertical shaft arranged at the right hand forward end of the engine. Cooling is by the thermo-syphon system. The carburetor is of special design, with 12 jets, which are covered when the throttle is closed by means of a sliding saddle incorporated with the barrel throttle. As the hand actuated lever above the steering wheel, or the accelerator pedal, is operated the throttle is slid along and exposes one or more of the jets, at the same time admitting more air by a passage below the throttle. In this way it is maintained that the mixture is preserved constant, whatever the speed of the engine.

The clutch is of the leather-to-metal cone type, enclosed and running in oil, and a clutch stop is fitted at the rear. The transmission affords three forward speeds and reverse. The rear springs act partially in the capacity of torque rods, but there is an additional torque and radius rod, spring controlled, which takes up any hard shocks which may be transmitted by the drive. This chassis is worm driven.

The motor on the five-ton machine also is a four-cylinder unit, with bore and stroke of five inches. In all other respects the larger chassis is identical in design with the smaller, with the exception of the rear axle and drive. This is termed a double reduction gear driven live axle of the bridged type. The Maudslay company claims to have been the first to introduce the bridged rear axle in Great Britain, at least for heavy loads. The whole of the load is taken on a solid forging, and the transmission gears, shafts, etc., may be withdrawn without the use of jacks or other extraneous aids. All Maudslay models are fitted with readily detachable cast steel wheels.

The 28-passenger char-a-banc shown was made to special order for P. Eastwood, Burney, Colne, for pub-

lic service work, the body being by Buckingham. This is of the so-called torpedo type, which has met with such ready acceptance by the British public. A special feature will be found in the arrangement of the doors, which open on either side alternately, the idea being to provide a stiff body construction.

FRENCH MILITARY TRIALS.

Gaulois Tires Very Prominent as Equipment on Competing Machines This Year.

The French military trials for trucks and tractors, which ended recently, is a 25 days' endurance test of commercial vehicles liable to be commandeered by the army in time of war. These tests have been conducted annually since 1909, and the prizes are in the nature of a subsidy, clean score machines carrying a dead load of 4500 pounds being awarded a purchase premium of 2000 francs, and those carrying a dead load of 17,500 pounds a purchase premium of 6000 francs. In addition, the winning trucks and tractors are eligible for a maintenance allowance of 1000 and 2000 francs a year respectively, for four years.

Each truck is accompanied on its journey across the country by a commissioned officer of the army, who must file a daily report of the performance of the machine under his observation. The dead weight carried is made up of small cases filled with broken stone, each weighing 100 pounds. The average speed imposed by the schedule is 10 miles an hour, and no vehicle is permitted to exceed 15.

The importance of the event has grown each year. In 1909, the entrants numbered 57, of which nine finished with perfect scores. In 1910, 36 entered and six finished. In 1911, there were 58 entries and 19 finished, while in 1912 there were 76 entries and 20 finished. This year, 98 trucks and tractors took part in the contest, the entrants including the following makes: Renault, Panhard-Levassor, De Dion-Bouton, Rochet-Schneider, Berliet, Saurer, Brasier, Clement-Bayard, Lorraine-Dietrich, Delahaye, Motobloc, Aries, Peugeot and Latil. Ninety-seven of the 98 were mounted on rubber tires, and 78 per cent. utilized those of the Gaulois make, represented in this country by the Gaulois Tire Corporation, 1926 Broadway, New York.

COMPETING WITH RAILROADS.

London Times Discusses the Subject Editorially, Citing Some Interesting Examples.

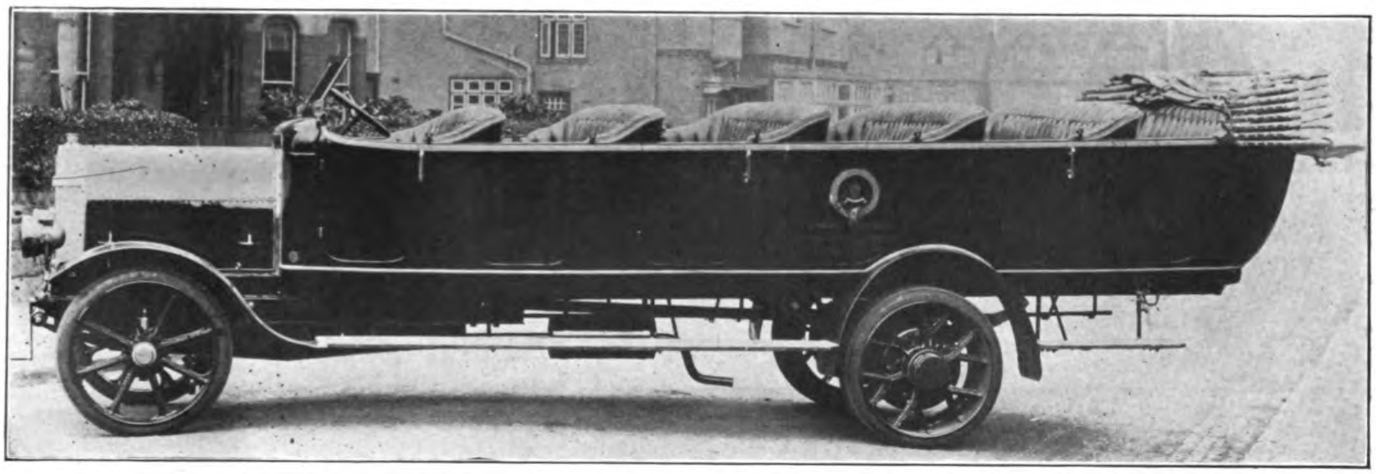
Transportation of freight and merchandise by motor truck in England has assumed such proportions that the railroads recently raised their freight rates, which step has naturally added to the popularity of motor truck transportation. The recent announcement at Los Angeles, Cal., that merchants there had combined to operate a motor truck line between that city and its nearby seaport, in competition with existing railroad service, indicates a repetition in the United States of conditions existing in England. Discussing the matter editorially the London Times in a recent issue said:

In the north of England there are cases even in the neighborhood of well managed railways in which considerable trade is being done between the collieries and wholesale distributing coal merchants by road, and more and more coal is being taken direct from the pit's mouth to the distributor and consumer without the agency of the railway truck.

In addition to this coal trade, in the neighborhood of Manchester and Liverpool, and all over the centre and south of Lancashire, elaborate arrangements have been in operation for some time past by which the cotton is taken up from the seacoast to the spinning mills and thence to other mills, where it goes through other processes, and eventually the manufactured goods are taken back, either to the seacoast for shipment or to a distributing centre like Manchester.

Other trades are now organizing road transports, and market gardeners, laundrymen and men of all the various trades which spring up on the outskirts of a great city are not only discarding their horses, but are now giving up the use of railways for the conveyance of their goods.

Some of the larger firms in London, such as Harrod's, Selfridge's, the Army and Navy stores, Maple's and others, now send out the majority of their goods within 100 miles' distance of London by road; and every year sees a comparative diminution in the proportion of goods and parcels sent by railway. It is clear, therefore, that any higher charges made by the railway companies must stimulate this existing tendency. Makers of commercial vehicles report excellent business, and we hear that firms of producers and distributors are contemplating a large addition to their road motors.



Maudslay 28-Passenger Char-a-Banc of the Torpedo Type, Fitted with Worm Driven Rear Axle of So-Called Bridged Design.

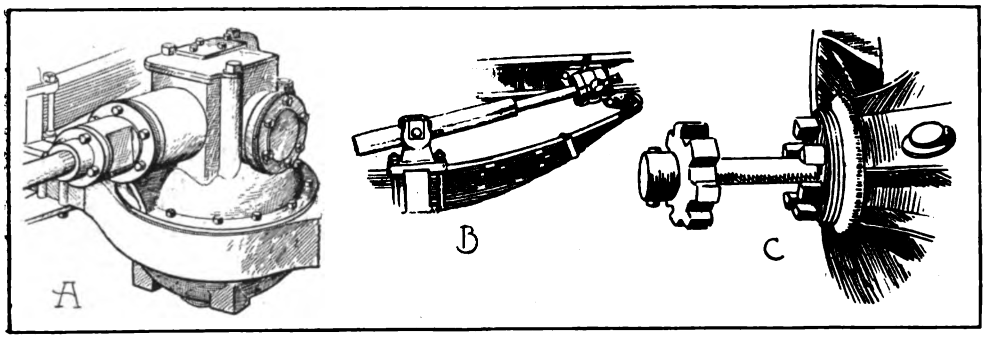
GENERAL NEWS FROM ABROAD.

Opportunities in Portugal—There appears to be a demand in Portugal for commercial motor vehicles, which will probably grow rapidly. At present there are about 30 motor delivery wagons and trucks in use

in Lisbon and 11 motor trucks and one motor delivery wagon at Oporto. German manufacturers have supplied the market to a large extent, but French and Italian makes are represented.

New German Traffic Regulations—Several important modifications have been made in the German motor traffic regulations, the Bundesrat having apparently concluded that automobiles should be constructed to suit the roads. The main modifications are the abolition of the iron tires and the restriction of axle weights and rim pressures. The section which required owners to fit rims with "smooth rims not calculated to damage the road surface," now provides that "rims should be shod with rubber or other elastic material and possess no unevenness likely to damage the roadway." The regulations also forbid the weight upon any axle to exceed six tons when a vehicle is loaded, and the pressure a centimeter of rim width is not permitted to be more than 743 pounds to each inch of width.

Overland in England—A new concern incorporated at London, England, is the Willys-Overland, Ltd.,



Constructional Details of Maudslay Chassis: A, Double Reduction Gear Casing; B, Spring Torque and Radius Rod; C, Rear Wheel Drive and Method of Withdrawing Live Axle Through Hub.

with an authorized capital of $50,000 in $5 shares. The incorporation is for the purpose of manufacturing and dealing in all kinds of passenger and commercial automobiles and the first directors are John N. Willys and Claude A. George. This firm will be the English branch of the Willys-Overland Company, Toledo, O., maker of Overland cars, of which John N. Willys is president. The truck firms controlled by the concern will be represented in the English market by the company.

Situation in South Africa—A great deal of attention is being given at present in South Africa to the use and suitability of motor tractors for farming operations. One of the largest land owners and agriculturists in the Transvaal conveys the information that in order to plow land deep and get moisture into the soil early it is necessary to have some system of kerosene plowing. He stated that the system of plowing with oxen, as is universally the case there, is cheap but slow, and by this process the land cannot be broken in the winter months as the ground is too hard, owing to the dryness of the atmosphere and the winds. Thus the advantage of the mechanically driven plow. There are numbers of farmers who would pay to have new land broken deep, but there is no system of doing it, and as, beyond a few steam plows, there are no examples upon which to work, no general movement for traction plowing has been inaugurated. The field promises much to manufacturers who enter and open it up.

Mining Work in Australia—There appears to be demand for one-ton tipping wagons in the mining districts of Australia. At present railroad cars are loaded in the mines, the contents being transferred to animal wagons at the completion of the run. Investigation of the possibilities with motor vehicles has indicated that they could be operated within the mines, thus eliminating the necessity for the second handling, with much saving in time and expense.

Possibilities in Spain—Since motor cars have come into more general use in northern Spain, there has arisen a demand for commercial vehicles. There are said to be excellent openings in Galicia and Asturia, providing the business is placed in the hands of a capable agency. In constructing cars for this market it should be borne in mind that the gasoline sold there is not very pure, and has a tendency to work great harm to the engines. The road conditions are now particularly good.

Want Trucks in Ceylon—The Morawakorale Planters' Association on the island of Ceylon has requested Charles P. Hayley & Co., to operate a service of motor trucks in that district. It is further announced that if this concern does not find itself able to take up this work, an effort will be made to secure a suitable contractor to take up the work, by advertisement.

Taxicabs in Japan—The success which has attended the establishment of a taxicab line in Tokio, Japan, has resulted in the proposition to start a similar service in Kakata, in the prefecture of Kukuoki.

No Steel Tires in Paris—The prefect of police in Paris, France, has issued an order that on and after Oct. 15 no heavy duty motor vehicles with steel tires shall be operated within the city limits. In addition, the speed limit of all commercial motor vehicles has been fixed at 7.5 miles an hour.

Opportunity in Colombia—A road making contractor in Bogota, Colombia, is making inquiry concerning motor trucks, having requested catalogues and other information concerning various machines from consular agents in that city.

THE A B C OF MOTOR TRUCK IGNITION.

Part XIII---Classifying the Various Types of Magnetos and Outlining Their General Characteristics---Construction and Operation of Inductor Designs Employing Stationary Windings and Produced in Both Low and High-Tension.

By C. P. Shattuck.

MAGNETOS utilized for ignition purposes may be divided into two general classes, high and low-tension, and these may be sub-divided into three types, namely: Double or compound armature (true high-tension), single and inductor (low-tension). With true high-tension magnetos the production of the primary current and its transformation into high-tension, is performed by the instrument itself, the armature carrying two windings, a coarse and a fine. With this type the exterior wiring is greatly simplified, there being but one wire in addition to those conducting the high-tension current to the plugs, and this is utilized to control the flow of electricity. There is no coil or transformer employed.

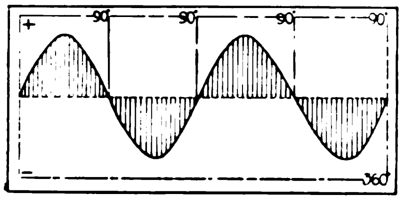


Fig. 67—Current Waves of K-W Magneto.

Magnetos having a single winding and employing a transformer coil to build up the low-tension current are also designated as high-tension, a term somewhat misleading to the novice. The coil utilized for building up the low voltage current so that it will bridge the gap at the spark plug points, or in other words, overcome the air resistance, is also called a step-up coil. These may be of a vibrating or non-vibrating construction, and as the principles involved are the same as those utilized in the induction coil, their operation will be understood fully by the reader. The third class of magnetos is the low-tension, that acts simply as a source of current, and is used in connection with a vibrating coil and a timer in the jump spark system of ignition. This type may be driven by friction, belting, etc., and with it the timing of the motor is not considered, as the speed of the magneto is in excess of that of the engine's crankshaft.

Inductor Magneto.

The inductor type of magneto differs from the armature construction in that its windings remain stationary in operation, the rotors or inductors revolving. The inductor may be one of two forms, a low-tension, having but one winding of coarse wire and employing a step-up coil or transformer, or a true high-tension, as in the case of the K-W.

Certain elementary parts of an inductor magneto are shown at Fig. 68, as well as the position of the driving shaft and inductors at different portions of a revolution. The upper drawing shows the magneto as it would appear with the end plates displaced, the lower illustrations depicting sections along the line X-Y of the corresponding drawing above them. But two magnets are shown, although there are more in a practical magneto because a series will supply more magnetic flux or energy than a single pair. These are securely fastened with all the north poles against the pole piece N, and all the south poles against the pole piece S. These are iron, but the base is brass. If an iron or steel base were utilized, part of the magnetism would pass through it instead of taking the proper course through the winding.

Construction of Inductor, Etc.

The stationary coil or winding is retained by the pressure of the pole pieces against it and by a clip. Two inductors are mounted on the shaft and rotate with it. To provide a path for the magnetic force, the inductors, core and shaft are composed of magnetic material. The direction of the magnetic flow through the revolving parts is shown by the arrows, the full ones indicating the path through the visible parts, the broken ones marking out the course taken through a normally invisible component.

In position A, the front inductor is adjacent to the pole piece N and the rear inductor is close to S. An iron path is formed between the inductors by the metal shaft and core. The cross section of the shaft is not large enough to carry all the magnetism, so the core assists by carrying part of the flux. The magnetism thus passes from the pole piece N to the front inductor, through the core and shaft to the rear one and thence to the pole piece S. The magnetism passes through the coil in this instance from front to back.

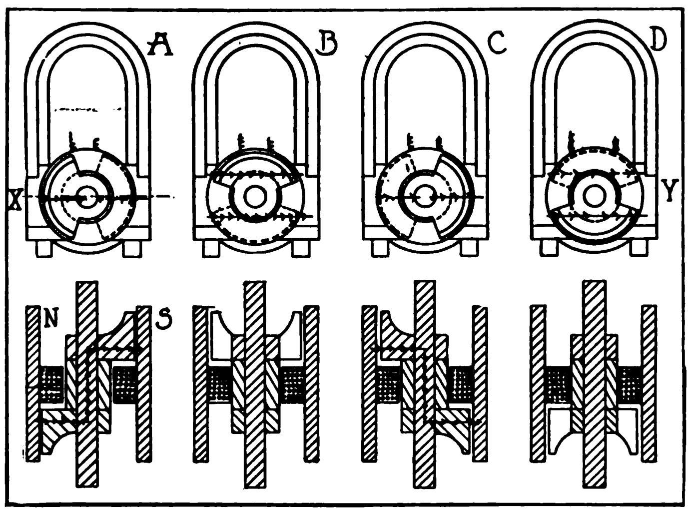

Fig. 68—Principles of Inductor Magneto.

In position B, the inductors are so placed that each one forms a path between the pole pieces N and S, and

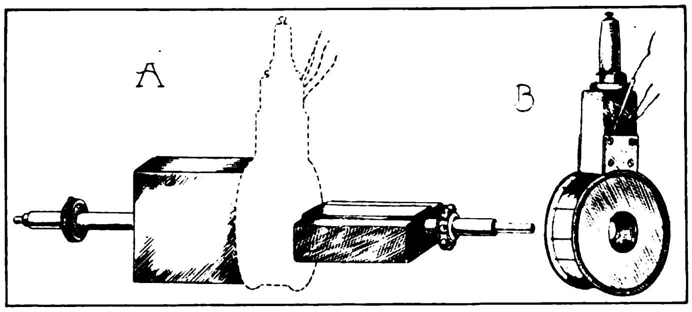

Fig. 69—Components of K-W Magneto: A, Rotors and Phantom View of Stationary Winding; B, Winding of Primary and Secondary Wires.

the magnetic force does not pass through the coil because of the shorter path provided by the inductor assembly. In position C, the conditions are similar to those shown at A, except that the flow of magnetism is reversed, passing through the coil from back to front. When the components are as shown at D, the same effect is obtained as at B, except that the front inductor is down and the back one up. In this position no magnetism passes through the coil.

It will be seen that as the inductors revolve the amount of magnetism passing through the coil is continually varying, thereby inducing in the winding an electromotive force, which is reversed twice during each revolution, when the inductors pass the positions A and C. As long as the direction of the magnetic flow remains the same, increasing and decreasing flow induces electromotive forces in the winding having opposite directions. Increasing magnetism in one direction and decreasing flow in the opposite path induces a current having the same course.

K-W Rotors.

At Fig. 67 is presented the shaft, rotors and windings utilized on the K-W high-tension magneto, a sectional view of which is indicated at Fig. 70. The rotors are constructed of fine laminations of soft Norway sheet iron riveted together and bored out to fit the rotor shaft. They are mounted at exactly right angles to each other, as shown in the drawing. The windings, which are shown at B, are concentric with the armature shaft, are mounted between the two halves of the rotor indicated by the phantom view at A, and remain stationary. These rotors collect the magnetism from one pole piece and conduct it through the centre of the winding to the opposite pole piece, producing a wave current each quarter revolution of the shaft. The winding shown at B is double; that is, it comprises a primary or coarse winding (low-tension), surrounded by a fine winding (high-tension).

The primary or low-tension energy produced by the revolving of the rotors as explained, is led to the circuit breaker, where its flow is interrupted, inducing a high-tension current in the secondary winding, which is conducted to the distributor, thence to the spark plugs. With the K-W magneto the condenser is bridged across the circuit breaker points, its function being to absorb the low-tension spark at the breaker points, caused by the interruption of the primary current. The safety spark gap was explained in the previous installment.

By referring to Fig. 70 the path taken by the primary and secondary currents may be traced. It will be noted that there are two wires leading from the stationary winding shown at Fig. 69 B. The secondary current passes upward vertically through a hard rubber terminal member to a bus bar, thence by an insulated high-tension lead to a brush and the distributor block, retained by a three-legged spider or bridge. The primary current flows through this bridge on its way to the circuit breaker, which carries a terminal to which is secured the wire leading to the switch, thence to the ground.

This lead is utilized for stopping the motor, as by closing the circuit the primary current generated by the magneto is diverted from the secondary winding, flowing through the wire to switch, thence to metal or ground. The circuit breaker mechanism and the distributor operate in the conventional manner.

The K-W magneto can be adapted to provide either one, two or four sparks a revolution of its armature shaft, as four current waves are produced each revolution. The difference in the construction of the cams is shown at Fig. 71, that at B being utilized for single, two and three-cylinder, four-cycle motors, while that

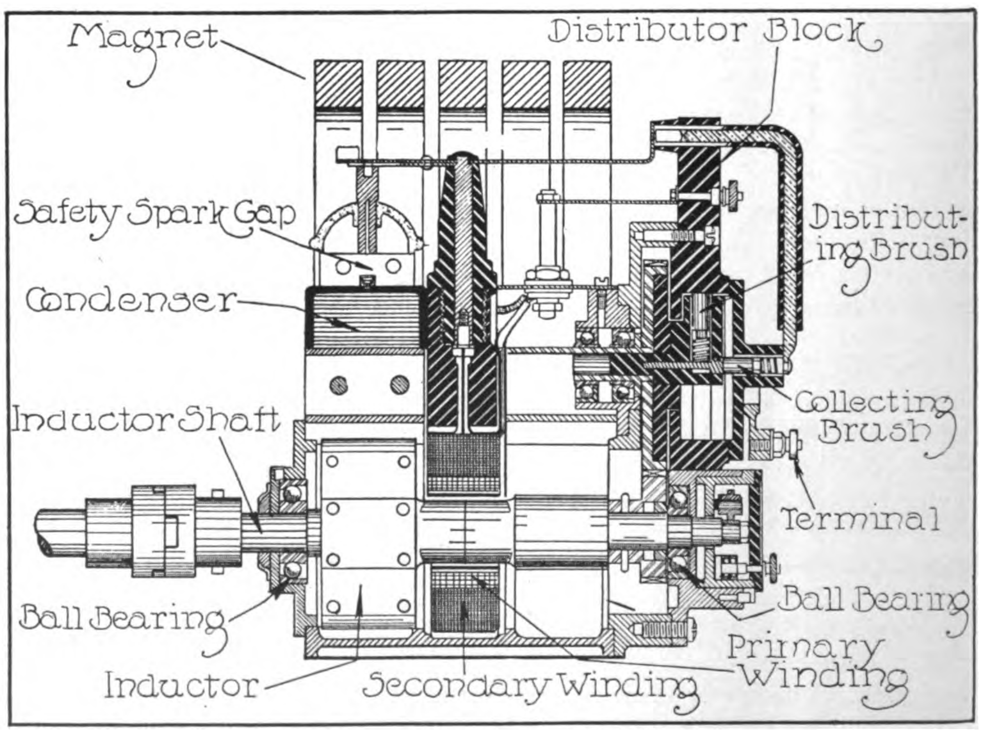

Fig. 70—Longitudinal Sectional Elevation of K-W Magneto, of the True-High Tension Type and Employing Stationary Windings.

at C is employed with four and six-cylinder units. Cam D is fitted to magnetos installed on eight-cylinder engines. All are driven at crankshaft speed, with the exception of the three and six-cylinder.

Cam B is employed with single-cylinder, two-cycle motors, C with two and three-cylinder units, and D with four, six and eight-cylinder engines. Drive is at crankshaft speed with the one, two and four-cylinder motors, 1.5 times with the three and six-cylinder units and twice the crankshaft speed with eight-cylinder engines. These cams are interchangeable.

This type of magneto is constructed to be positively driven in either direction, clockwise and anti-clockwise, the rotation being denoted by an arrow on the brass dust cap located on the driving end of the shaft.

(To Be Continued)

Ed. Note—The next installment will deal with other forms of low-tension magnetos, including those designated as high-tension.

TRUCK VS. MULE TEAM.

Some Interesting Comparative Figures Resulting from Week's Test in Quarry Work.

A recent test covering a week's operation of motor trucks and mule drawn wagons in the quarry service near Baltimore, Md., was conducted with interesting results. McMahon Bros. of Mt. Washington, Md., is using a five-ton and a four-ton Mack, made by the International Motor Company, New York City. These machines are fitted with automatic dumping bodies, and the Schwind Quarry Company is using them to haul broken stone for road building.

In order to show what could be done in this line a week's test was conducted with a five-ton Mack truck with automatic body in competition with a four-mule team wagon, hauling broken stone for road building from the quarry. The truck had to make 10 miles to a round trip to nine for the team, on account of having to go a mile out of the way on the trip from the quarry in order to avoid a bridge which was too weak to carry it loaded. One mile of the trip loaded was up a 14 per cent. grade.

The average amount of gasoline used was 21 gallons; oil, two gallons. The average number of working hours was 10; average time loading, three minutes; average time unloading, 10 minutes; total load carried, 60,000 pounds; number of trips, six; total mileage, 60. There were three rainy days during the test, so that the roads were soft and muddy.

Another advantage in the use of the truck was in the spreading of the stone. It took the truck 10 minutes to do this work, which the contractor stated was done better than could be done by hand, and the labor of two men working with shovels for one hour was saved. This spreading was regulated by opening the tailboard the proper distance and letting the truck travel slowly over the road with the body. The following figures represent in concrete form the results of the comparison:

Four-Mule Team Hauling 4.5 Tons a Day 27 Miles.

Four mules at $325 each	$1300.00	
Harness	75.00	
Wagon	250.00	
Total investment		$1625.00
Interest on one-half investment at 6 per cent.	$48.75	
Insurance on team	32.50	
Depreciation, 20 per cent	325.00	
Fixed charges a year		$406.25
Fixed charges a day		1.85

Assuming 225 Working Days a Year.

Wages a day	$1.84	
Feeding at 60 cents a head	2.40	
Stable man	.25	
Doctor	.20	
Shoeing	.30	
Repairs	.20	
*140 days' feeding at 40 cents a head, $224	.99	
Daily operating cost		$6.18
Fixed charges a day		1.85
Total daily operating cost		$8.03

Five-Ton Dump Truck, Hauling Five Tons a Day 60 Miles.

Truck		$5300.00
Interest on one-half investment at 6 per cent.	$159.00	
Insurance on truck, 2.5 per cent. on 80 per cent. of one-half value	53.00	
Depreciation on truck, not including tires	480.00	
Fixed charges a year		$692.00
Fixed charges a day		3.07

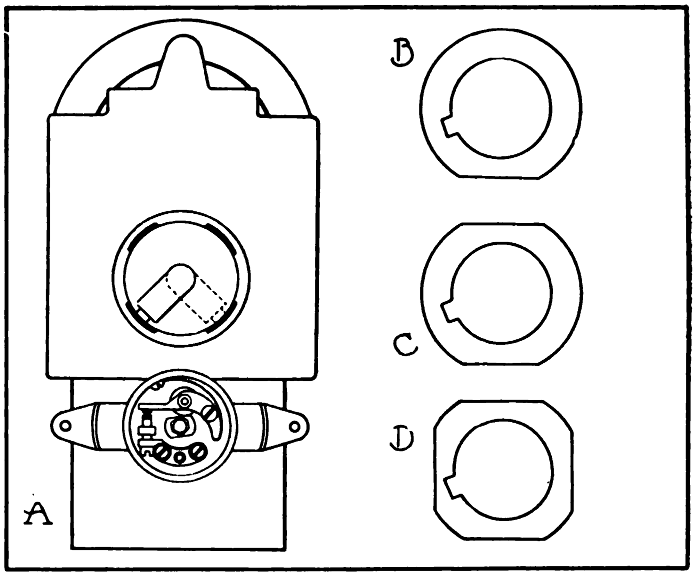

Fig. 71—Construction of Inductor Type of Magneto: A, Distributor and Circuit Breaker; B, C and D, Cams for One, Two and Four-Cylinder Instruments.

Assuming 225 Working Days a Year.

Wages a day	$2.50	
Maintenance, 4.5 cents a mile	2.70	
Tires, 6 cents a mile	3.60	
Gasoline, 4 cents a mile	2.40	
Oil	.60	
Daily operating cost		$11.80
Fixed charges a day		3.07
Total daily operating cost		$14.87

*Due to the mules not working, quarry being shut down, owing to weather conditions.

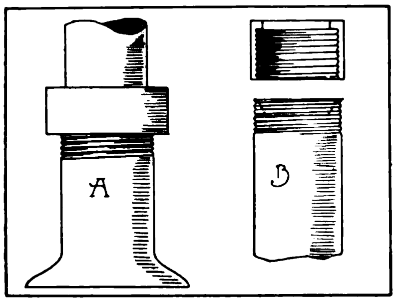
It was shown that a four-mule team hauls 13.5x4.25 at 57.37 ton-miles a day, 13.9 cents a ton-mile.

Five-ton truck hauls 5x30 at 150 ton-miles a day, 9.9 cents a ton-mile, or a saving of four cents a ton-mile, or $6 a day.

The dealers in Atlanta, Ga., have decided upon the week of Nov. 8-15 for their annual pleasure car and motor truck show, to be held in the Auditorium.

HINTS FOR PROPER MAINTENANCE.

EXHAUST pipes are constructed of steel tubing and are easily damaged. The fitting of a new tube requires care in the shaping, as it is an easy matter to kink the material, this not only resulting in an unsightly piece of work, but one that obstructs the flow of the gases. A method of bending is shown in an accompanying illustration, from which it will be seen that the pipe is passed through the hole in the block, while the copper loop forms the fulcrum for the lever. The leverage obtained enables short bends to be made without kinking, and it is secured by gradually moving the block, so that the pressure is not exerted continually at any one particular point during the operation.



Stuffing Box for Leaky Tappet Guides.

Before commencing to bend the pipe, a wire templet of the shape required should be made. If the tube be of copper it should be filled with resin, run in while hot and allowed to cool. Three articles are needed, as will be noted by the drawing: First, a hard wood block with a hole slightly larger than the diameter of the pipe; second, a loop made from an old piece of copper pipe, and third, a stout pinch bar of convenient length.

In bending steel tubing the same process is utilized, but the pipe is filled with sand, and the block should be of metal. The pipe is heated at the point at which the bend is desired, and is cooled off slightly on the side which forms an inner radius of the circle, to prevent kinking. A small hole should be drilled in the pipe in any convenient position to allow for the expansion of the sand when heated. Otherwise the contents are likely to be blown out during the bending process. Before fitting the pipe to the part it should be tested and inspected for flaws.

TAPPET GUIDE STUFFING BOX.

It is not an uncommon occurrence, upon lifting the hood of an old pleasure car that has been converted into a commercial vehicle, to note that the power plant is covered with dirty lubricant. This is generally due to worn tappet guides, although sometimes the oil will work out around the end bearings of the crankshaft. To fit new tappets and guides involves some expense, and the trouble may be remedied, if the design of the motor will permit, by making stuffing boxes as shown in an accompanying illustration.

In this instance the valves and pushrods were displaced and a thread cut on the outside of the guides, as shown at B. The interior of the guide was countersunk, as indicated by the dotted lines. The stuffing box was constructed of a piece of heavy brass tubing, drilled to form a lip at the top to hold the packing, and threaded inside. By using one-strand graphited candle wicking, soaking it with oil in the stuffing box, and screwing it down properly, the loss of lubricant from the crankcase was prevented. The device could be improved by using a lock nut below the stuffing box, this depending, of course, upon the space between it and the crankcase. The same method could be applied to some types of worn valve stem guides where considerable auxiliary air is noted.

RENOVATING FELT WASHERS.

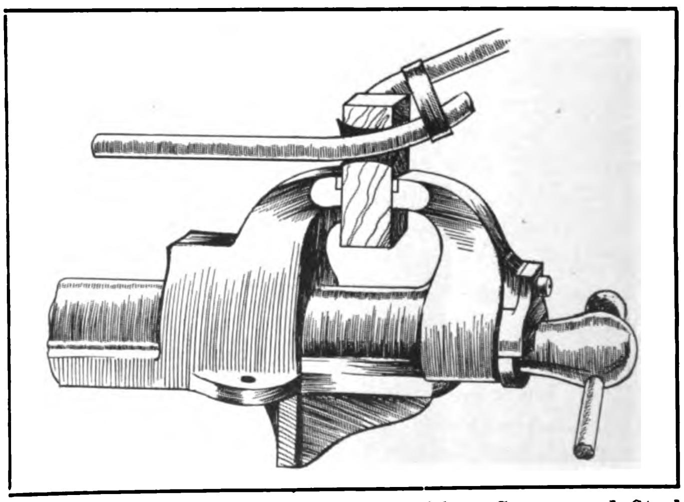
Felt washers that have become hardened or caked with old lubricant may be made serviceable by soaking them in gasoline or kerosene and flexing the material.

CARE OF THE COMMUTATOR.

Magnetos are generally fitted to commercial vehicles, but some machines are equipped with a low-tension magneto-generator having a timer and coil, such as the model T Ford for example. As the commutator is an important factor in the ignition system, breaking as it does the primary circuit, it should be cleaned and lubricated from time to time.

If it is accessible, it is a simple matter to remove the cover and wash out all dirt and old lubricant with gasoline, after which the working parts should be oiled, although some favor vaseline. If the timer cover cannot be displaced without considerable trouble, it may be washed by utilizing an oil can filled with gasoline and squirting the fuel through the lubrication opening.

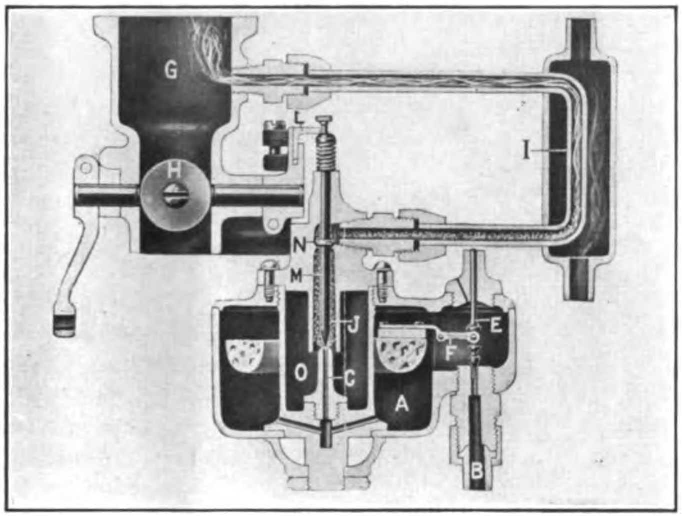
If the car has seen considerable service it will be well to examine the timer bearings, fibre and contact blocks to note if they are worn. If the blocks are uneven the roller will have a tendency to jump, creating a poor contact, as well as affecting the operation of the motor. It is a simple matter to remove the fibre ring, take it to a machine shop and have it trued up.



Suggestion for Bending, Without Kinking, Copper and Steel Pipes of Large Diameter.

CHAMBRAY CARBURETOR UTILIZES HEAVY FUELS.

VAPORIZING and maintaining the vapor up to the time the mixture is ignited in the cylinder is one of the problems confronting designers of carbure-



Chambray Heavy Fuel Carburetor Utilizing Heat of Exhaust Pipe for Preventing Condensation of Mixture After Complete Vaporization.

tors and vaporizers utilizing heavy fuels. The Chambray Carburetor Company, Detroit, claims to have solved this problem in its Chambray carburetor, the most prominent feature of which is the conversion of the primary mixture, including the fuel and a small percentage of air, into a combustible gas before it is introduced into the intake pipe of the motor. It is also held that condensation or precipitation is eliminated, that the highly gaseous state is so fully maintained that it will burn when lighted as with any hydrocarbon gas.

Outwardly the design resembles the conventional carburetor, but its components differ, as will be noted by the accompanying sectional illustration. The fuel, whether it be kerosene or the heavier distillates of petroleum, enters at B, and the height of the fluid is regulated in the conventional manner by a needle valve. With the valve H closed, the primary air is drawn into the chamber O and passes up the tube J, carrying with it a jet of liquid from the nozzle C. The size of the orifice through which the fuel issues is regulated by the needle M, which in turn is actuated by the throttle H. Obviously, the amount of liquid may be augmented or decreased as best meets the requirements of the motor.

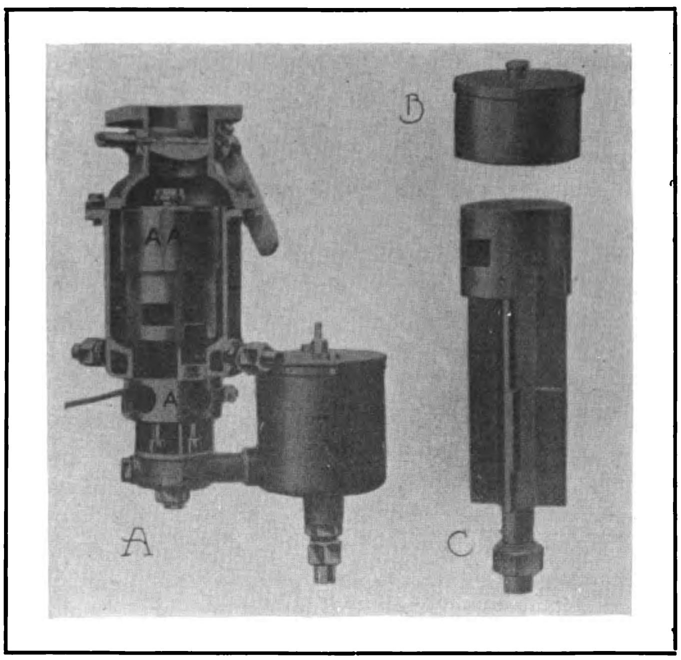
The primary air is controlled by the valve N, and it is stated that the construction maintains a high velocity. The resulting mixture, which passes through a copper tube I, located in the exhaust manifold, is thus heated and gasified. Although at first the mixture is held to be rich, through the action of the member L and resulting heat of the exhaust, it is stated to be productive of perfect combustion and to be independent of atmospheric changes. Three adjustments are incorporated, a low, intermediate and high.

The company is producing a priming device for the carburetor, whereby fuel is drawn direct from the supply tank through a .0625-inch copper tube. Along the course of this tube is an electrical heating device, current for which is supplied by a four or six-volt battery through a wire in the heating tract. It is stated that this construction will enable the starting of the motor cold on kerosene. A plunger valve is located in the priming attachment, which may be operated either from the seat or from the front of the machine, as best meets requirement.

SMITH FOUR-JET CARBURETOR.

A carburetor which has four jets and which is said to have been productive of motor efficiency as well as economy of fuel, is the Smith, the creation of S. Smith & Son, London, England. As will be noted by reference to the sectional view presented at A in an accompanying illustration, the design makes for simplicity and accessibility of components. It is stated that a new jet may be fitted in two minutes.

The first jet is of larger bore than the others and is used for starting, the second, third and fourth being brought into operation consecutively, and automatically. Centrally located in the main body of the device is the automatic controlling valve, which slides up and down, and as the surface is constantly washed by the moving mixture, it is kept free from foreign elements. It is stated that the float chamber may be fitted in eight different positions in relation to throttle valve. Not only is the mixture automatically controlled by the valve member A A, but the latter rises in propor-



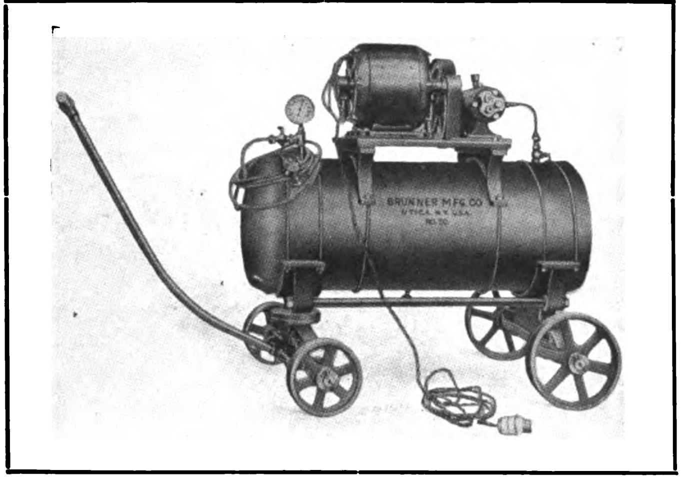
Smith Four-Jet Carburetor, Having an Automatic Controlling Valve: A, Sectional View; B and C, Choke Tube and Combination Piston and Sleeve Valve.

tion to the speed of the motor and uncovers the port of each succeeding choke tube, thus bringing the jets into action.

Each jet is calibrated and stamped with the number of cubic centimeters of fuel passing a minute, with suction equal to a six-inch head of gasoline, this condition being automatically maintained on each jet when in operation, irrespective of the speed of the engine. The adjustment is effected by changing the jets until the mixture is correct at all speeds. By means of a rotary sleeve valve operated by a lever, the driver can alter the mixture from the seat to suit varying atmospheric conditions. Connection to the water circulation system is made by six varying connections, a design making for easy installation.

GARAGE AND SERVICE STATION EQUIPMENT.

THE Brunner Manufacturing Company, Utica, N. Y., maker of the Parker and other forms of compressors, is producing what is termed the No. 50 portable outfit, which is high grade in every particular and designed to meet every requirement of service. It is a complete unit, as will be noted by an accompanying illustration, and is easily operated, a socket being fitted to a convenient circuit.



Brunner Portable Air Compressor Outfit, Utilising Electricity for Driving the Compressor.

The compressor has a capacity of one cubic foot of free air a minute, and the utilization of a safety valve permits of any desired pressure. The tank is of extra heavy steel, tested to 250 pounds, and is 30 inches long and 12 in diameter. Its capacity is 15 gallons (two cubic feet), and it is claimed that it will inflate two flat tires and harden up from eight to 12 according to their size. When the container is filled it will inflate one 36 by 4.5-inch casing to 90 pounds, also three ordinary sizes, before it is necessary to start the motor.

The motor is an electrical unit, .25 horsepower capacity, and is capable of starting the compressor against 120 pounds, and increasing it to 150. Either alternating or direct current motors are supplied, and of any voltage and cycle. The gears are held to be noiseless through the use of a rawhide pinion and a cut cast iron spur. The truck carrying the equipment is substantially constructed, the forward axle revolving on a king bolt, no casters being used. The forward wheels are cast iron, eight inches in diameter, the rear members 10. Patented cushion tired wheels are furnished at a slight extra cost. Each outfit includes 12 feet of .1875-inch rubber tubing, one stop cock, a 2.5-inch polished brass gauge, a globe valve controller between compressor and tank, electric cord and a tire connection. The finish is gloss black enamel. The fittings are polished brass and copper. The cost of operation is stated to be from one-quarter to two cents an hour.

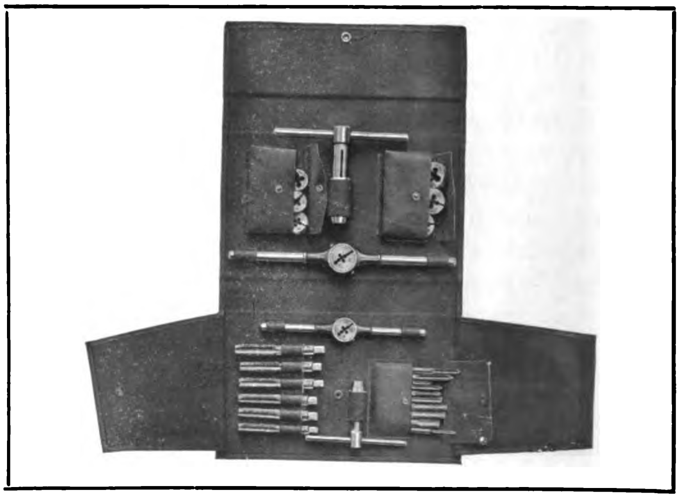
LIGHTNING REPAIR KIT.

The Wiley & Russell Manufacturing Company, Greenfield, Mass., maker of screw cutting tools, is marketing the Lightning auto repair kit shown in an accompanying illustration. The screw-cutting assortment is very complete and was designed with special reference to the screw threads found on the model T Ford and other medium priced cars. It comprises 16 taps, 16 dies, two stock and two tap wrenches, permitting of the cutting of threads from 18 to 32 an inch, also pipe threads; in fact, the equipment is adapted to a large variety of work and different makes of cars, etc.

The assortment comes in a genuine goat skin leather case, having compartments to protect the cutting edges of the tools, and the container is not only compact but very durable.

DETECTORPHONE.

An instrument for locating mysterious knocks or noises by an adaptation of the microphone principle is being produced by the Boston Talking Machine Company, 41 West street, Boston. The device comprises a receiver, similar to that employed by telephone operators, and the 'phone member. The latter is provided with a microphone button, changing the position of which is held to magnify the sound through the vibration travelling up the rod through the button, thence to the receiver and ear of the operator.



Wiley & Russell Lightning Auto Repair Kit, Containing Complete Assortment of Screw Cutting Taps, Dies, Etc.

CORRESPONDENCE WITH THE READER.

Generator Gives Trouble.

(43)—We are using a model T Ford for delivery purposes and frequently the car is employed to make night deliveries. Our driver complains that the carbide generator which came on the car gives trouble. We have fitted new burners and tubing but the trouble continues. We have also tried different sized carbide. Have been told that the generator is faulty. Any information will be duly appreciated. W. E. K.

Philadelphia, Penn., Aug. 21.

The trouble referred to is caused by more or less moisture in the gas generated, which condenses in the tubing leading to the burners. It is experienced with some types of generators, and with the design referred to can be cured by utilizing a condenser or trap in the piping between the generator and the lamps. It should be placed in the lowest point of the line, and will collect the moisture. These traps may be purchased or may be made at home.

At Fig. 1 is shown a condenser which may be constructed easily and which is inexpensive. The material required comprises a T coupling, a petcock and a piece of brass tubing. The latter is slipped over one end of the coupling and petcock as shown in the drawing and the joints soldered to make them gas tight. The petcock is necessary as it permits draining of the water. The device is clamped to the underside of the running board by strips of brass secured by screws. It is advisable to have the section of the coupling to which the petcock is secured at least an inch long to provide a suitable retaining capacity.

Lamps Burn Out.

(44)—Upon my suggestion my employer allowed me to fit electric headlights to our Ford delivery car. Since putting on the lamps I have experienced considerable trouble with the bulbs burning out. If I employ a bulb that won't burn out the light is poor at low speeds. On the other hand a bulb that gives me good light at low speeds burns out at high. What is the trouble and how may it be remedied? R. A. C.

Brockton, Mass., Aug. 23.

The voltage of the current generated by the flywheel magneto on the car mentioned varies with the speed of the motor, and the burning out of the filaments is due to too high a voltage. Similarly, when the motor is operating at low speed the current is not of sufficient value to heat the filament properly.

It is probable that the bulbs employed are not adapted for the work. There is a device upon the market which it is claimed will so regulate the current that a maximum light is obtained regardless of motor speeds. It is called the J & B light controller and is constructed especially for the model T Ford car.

Cleaning Radiator.

(45)—I have been experiencing trouble with the radiator of my car getting very warm. The water does not boil but it gets intensely hot. Have inspected the water pump and oiling system and both work perfectly. Carburetor has been giving no trouble and the mixture seems to be very good. A friend of mine advised the use of sal soda to clean the radiator. Kindly advise me if the use of sal soda would injure the radiator?

Pittsburg, Penn., Aug. 21. C. G. B.

The use of a solution of sal soda and water is recommended by makers of radiators and is not harmful. The heating of the radiator may be due to deposits caused by the continued use of the same water, which creates a scale which is due to minerals in the fluid.

The water should be drawn from the radiator and the cooler refilled with the soda preparation. Dissolve as much of sal soda in the water as possible, and use as much fluid as the system contains. It is a good plan to run the motor with the soda solution, the length of time depending on the condition of the radiator. If the old water was badly discolored, it may be advisable to operate the machine for an hour or more with the soda solution in the cooler.

After removing the solution replace with fresh water and continue to change it until all signs of discoloration are eliminated. Some make it a practise to insert the nozzle of a hose in the radiator filler member, running in fresh water with the motor operating. Of course the petcocks should be opened to allow the fluid to run out.

Proper Advance of Spark.

(46)—Will you give me some simple, concise advice on the advance of the spark lever? I have heard varying opinions. The motor in question is a four-cylinder, four-cycle and is used on a car of one ton capacity. W. S.

Lynn, Mass., Aug. 20.

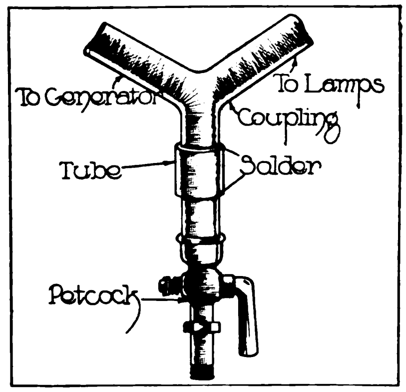


Fig. 1—Home Made Gas Condenser.

The spark lever should be advanced in proportion to the speed of the motor, and the amount of the lead is best determined by experience. Theoretically, the spark is supposed to occur when the piston has completed the compression stroke and to have begun the firing or impulse stroke. In practise, the time of the spark occurs earlier, so that the ignition of the mixture will be more or less complete upon the piston starting downward. At very low speeds, as in starting, the timing is so set that the spark takes place slightly after dead centre. As the speed of the piston is increased, the spark is made to occur earlier through movement of the breaker box or timer, which is actuated by the lever on the steering wheel. It is considered good practise to advance the spark in proportion to the speed of the motor and to retard it when the slightest knock is noted. There is a limit as to the advance; that is, beyond a certain point the efficiency of the engine is not improved.

The Gulf Refining Company, which owned 12 White trucks, has purchased 14 more that are to be delivered at different stations where they will be used for the haulage of oil products. The statement is made by the White Company that 18 of the leading oil companies have bought 145 White trucks.

New Commercial Car Accessories

Winsor Adjustable Valve Remover.

A valve lifter having interesting features, in that it may be adjusted to meet the requirements of varying motor design and is positive in its action, is the Winsor patented adjustable valve remover, made by the Winsor Manufacturing Company, 253 Eddy street, Providence, R. I. It differs from conventional designs in that the mechanism holding and preventing movement of the valve during the compression of the valve spring is screwed into the spark plug opening, a construction preventing slipping of the tool as well as providing a stable leverage. This spindle is screwed into the opening by the fingers until it seats against the valve head, and incorporated with the spindle is a barrel member which revolves. This permits of operation at any desired angle. The barrel is provided with a number of notches into which is hooked one end of a chain, and the free end of this is hooked to a lever. By depressing the lever, which is extra long, it is a simple matter to compress the valve spring and remove the locking mechanism. The spark plug valve cap is utilized for the exhaust members. Extra barrels are furnished to fit different threads at a slight cost. The Winsor is moderately priced and constructed of high grade material. It comes with a black enamel and a nickel finish.

Underwriter Automatic Valve.

Many disastrous fires, originating through a back fire of the carburetor, or ignition of the fumes of the fuel, could have been prevented had it been possible to shut off the fuel supply, confining the blaze to the contents of the carburetor. The Underwriter Valve Company, Industrial Trust Building, Providence, R. I., is marketing the Underwriter automatic valve, which is incorporated in the fuel line between the fuel supply and the carburetor, and which is so designed that the flow of gasoline is automatically shut off when the device is exposed to a certain temperature. This action is secured through the utilization of a link, which in fusing and separating actuates a spring which closes the valve proper. The link section of the valve is removable without disturbing the other parts, and the device is non-leakable. New links may be replaced easily, or a wire may be utilized to retain the valve in an open position until a new fuse can be fitted. The valve itself is constructed of bronze, copper and German silver, weighs but seven ounces and is very compact. The valve bodies are furnished in .125 and .25-inch pipe connections, although special sizes are constructed to order.

Dover Radiator Filler.

Many concerns are particular as to the appearance of their machines and maintain these in first class order, especially the trimmings. In renewing the supply of water in the radiator with an ordinary pail or hose, the polished surface is apt to be discolored unless care be exercised in the operation. The Dover Stamping & Manufacturing Company, Cambridge, Mass., is producing a handy article for this work in the form of a six-quart container having a hooded spout, which permits replenishing the supply of fluid without the usual spilling. The handle is serviceable, and the filler is constructed of heavy galvanized steel. A brass strainer is fitted, preventing the entrance of foreign elements into the cooler. The Dover radiator filler is moderately priced.

Apco Ford Anti-Rattlers.

The Auto Parts Company, Providence, R. I., maker of Ford specialties and accessories, is offering a new device known as the Apco Ford Anti-Rattler. It is made in two styles, one with a screw adjustment and the other with a disc. They are utilized to eliminate the rattle caused by wear of the front axle radius rod ball bearing, which is constructed without means for adjustment. The screw design makes for great convenience in that fine adjustments may be made, the operation involving the removal of a cotter pin and rotating the screw plug until a slot in it registers with the housing member. The other type employs a number of thin discs. A coil spring provides for a cushioning effect, eliminating vibration as well as undue wear, and presses a hardened cup shaped cone against the ball proper. Both types are moderately priced and guaranteed.

Dalitz Spark Plug Tester.

The Dalitz Manufacturing & Sales Company, 803 Union street, Seattle, Wash., is introducing the Dalitz spark plug tester and terminal, which is a simple and easily attached device for testing faulty ignition, locating knocks, and for preventing operation of the car by others than those intended. It is secured to the spark plug, being retained by the regular terminal nut, and provision is made for attaching the secondary wire. The device includes a movable metal part with an insulated handle, and normally there is no contact between the metal and the ground or base of the plug. By sliding the movable part, the current is grounded, thereby cutting out the cylinder. The tester may also be utilized to note the strength of the spark by making a gap, and the ignition system may be locked by grounding, as above described.

Sexton Oil Filter.

In changing the lubricant in the crankcase of a motor, the old oil is generally thrown away. The Sexton Can Company, 2 Hartford street, Boston, is manufacturing the Sexton oil filter, which is a sturdily constructed vessel 10 inches in diameter and 20 high, although different sizes are made to meet individual requirements. The can is provided with a hinged top and a series of filtering members, also a faucet for removing the filtered oil.

Hoyt Pocket Voltmeter.

The storage battery utilized for ignition or lighting, requires proper care and the cells should be tested from time to time to note their condition. The Hoyt Electrical Instrument Works, Penacook, N. H., maker of current indicating devices, is marketing a voltmeter of the pocket type, which is guaranteed to be accurate. The new meter, which is of the coil type, comes in a sturdy case, averages about 40 ohms a volt, is dead beat in action, slightly larger than a watch, and is moderately priced. Being designed especially for storage batteries, it forms a valuable addition to the car or garage equipment.

GASOLINE LOCOMOTIVES ECONOMICAL.

Large Saving Made by Waltham Trap Rock Company in Handling 500 Tons of Stone Daily on Industrial Railroad in Its Quarry, by Change from Manual Work.

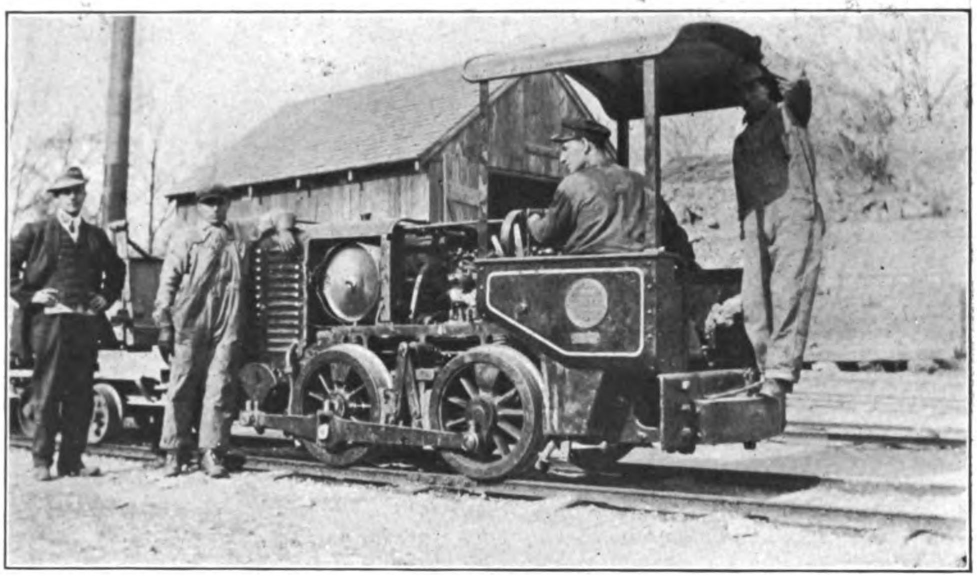
AT THE quarry of the Waltham Trap Rock Company, near the Stony Brook station, Weston, Mass., an industrial railroad is in operation such as is used by many large contractors when the operations are of considerable proportions. This installation is interesting from the fact that a gasoline locomotive is used instead of the usual steam locomotive or cables operated from stationary engines, or horses. As this company has an output of 500 tons of crushed stone daily, and it is intended to increase this to 600 tons a day, it will be understood that the haulage is a matter of great importance, and an economy of a fraction of a cent a ton would amount to a considerable sum in the course of a year. The company operates about nine months of the year, stopping work during January, February and March as a rule.

Industrial railroads vary in size of ties, rails, rolling stock, etc., and the cars will contain from one to three cubic yards of sand or stone. These installations are found very serviceable for excavating and filling, as the track can be laid on almost any reasonably level surfacing and can be quickly removed or changed. Generally the rails and ties are assembled in sections so they may be conveniently handled, and these sections are bolted together, the switches and the cross-overs being similarly constructed.

Frequently large contractors have tracks, cars and locomotive included with their regular equipment, and whenever a job warrants the railroad complete is shipped with the usual paraphernalia. The steam locomotive or the engine used for cable haulage requires fuel and water in considerable quantities, and in many instances the engineers must be licensed, while there are other requirements, such as boiler inspections and the line, to say nothing of the items of expense, including insurance, that may be incurred. When power is not used the track may be laid with sufficient grade so that the loaded cars may be run by gravity from the point of loading to that of unloading, and then they are hauled back by animals or are pushed by men. Where the job is large railroads have been operated in buildings, and under such circumstances manual power is always used.

The Waltham Trap Rock Company has a quarry to which a spur track extends from the Boston & Maine tracks, and beside the track is the crusher. The crusher is located on the steep side of a hill, and about 15 feet above the railroad is the boiler house, and the base of the conveyor that takes the broken rock to the crusher. From this point the quarry extends into the hill like a great fan, the excavation being at the rear close to 100 feet below the surface of the ground. From the crusher to the furthest point into the trap rock ledge is nearly 700 feet, and the bottom of the quarry is worked as close to a level as is practicable.

When the men burrowed into the hillside for a time handling the rock was a matter of ease, but as the work progressed a railroad was believed to be the only solution, and the equipment was purchased. The cost of a locomotive was large, and with the necessary expenses and limitations in connection with its use the management decided to have the men push the cars. This was not expensive so long as the distance was short, but when the trackage had increased to about 1000 feet, and it was 600 feet from the broken rock to the crusher, 10 or 12 men were necessary to push the cars, although the track was laid to have a slight grade. While the men could work a part of the time on loading, they were kept busy most of the time with the cars, and last year the company decided to purchase a locomotive.



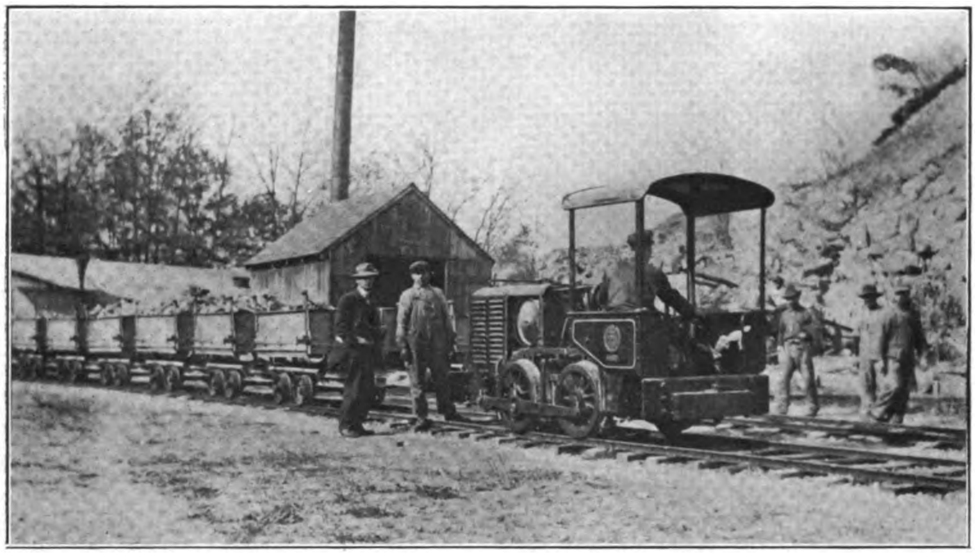
Baldwin Gasoline Locomotive, 40 Horsepower, That Hauls 500 Tons of Broken Stone Daily in Nine Hours at the Quarry of the Waltham Trap Rock Company.

The machine decided on was built by the Baldwin Locomotive Works, Philadelphia, and it is designed for industrial railroad work. The motive power is furnshed by a four-cylnder, water-cooled gasoline motor, with a cylinder bore of 4.25 inches and stroke of 5.5 inches, developing 40 horsepower at 1000 revolutions a minute. This engine is installed longitudinally

in the chassis, and its position is reversed with reference to the customary motor vehicle installation, the flywheel being forward and the starting crank located in the centre of the cab. When first received a dry plate clutch was used, but this was not satisfactory, and it was replaced by a Hele-Shaw multiple disc clutch, such as are usually used in motor vehicles.

The locomotive is driven by four wheels with connecting rods coupled to a cross shaft that is driven by bevel gears, with clutches that afford high or low speed and reverse, the cross shaft carrying counter weights, so that there is no dead centre. In mechanical phraseology, the drive is through patented Scotch yokes. The gear reduction is large and the locomotive is supposedly limited to 10 miles an hour on the high speed, but it can be driven at nearly double that speed.

In the work that is done in the quarry the locomotive is driven 10 hours a day and over the track that is laid out like the ribs of a gigantic leaf, there being a main line with three branches, each of which has three branches and two of these two more, so that cars can be drawn to the end of the lines and loaded with the broken stone. The rock is blasted and sometimes thousands of tons of stone are loosened, and the pieces are sometimes blasted or broken with hammers. The cars are loaded by hand and are hauled to the other end, where they are dumped at the crusher and then backed out on a siding. The company has about 20 cars, and these are kept in motion as much as is possible, some days there being as high as 250 loads drawn. The machine will haul 15 loaded cars, and frequently from three to a half-dozen are drawn at a time.



Gasoline Locomotive and Train of Steel Cars of Two Tons Capacity, Used on Industrial Railroad of the Waltham Trap Rock Company.

The locomotive is operated by an engineer, who has a state automobile driver's license, not from necessity, but because he has had a thorough training as an automobile mechanic, and he is using a motor such as might be used in a five-ton truck. The machine is operated by levers that control the speeds and a wheel that varies the carburetor mixture. One of the chief difficulties experienced with it was in adjusting the carburetor to secure a sufficient supply of fuel so that the motor could be operated slowly, and since this was accomplished the locomotive has been driven with every degree of satisfaction. The speed of the locomotive is slow at all times and naturally the desire is to obtain power at comparatively low engine speed.

The cost of operation is small, for as a rule between three and four gallons of gasoline will suffice for the haulage of from 200 to 250 cars and from 400 to 500 tons of stone, and about a quart of oil will meet all lubricating requirements. The radiating system is large, and the engine has never been heated above a normal temperature, but while the fan draws the air through the two radiators the hood is often lifted to allow free circulation about the motor. The locomotive weighs about 3.5 tons and is extremely solidly built, and it is surprisingly easy riding. Occasionally it leaves the rails, but it climbs back on to the metal again like a cat. It is kept in a small house in which is a pit, so that men may work under it if necessary. When the work for the year is completed the machine is well oiled and greased and stored in this building until the time for resumption of work.

The track is laid wherever cars are wanted, and by disconnecting the sections it can be taken up and relaid without difficulty, this work being often necessary when blasting is done. During the winter season the track is left in the quarry and in the spring a little blocking and oiling the switches will place it in good condition.

As to the economy of the locomotive, this cannot be shown in dollars and cents, for the company has kept no record that would specify it, but to do the work by hand would require at least 10 or 12 additional men than are now employed, and these would be paid the prevailing day wage. Undoubtedly these men might be used to some advantage, but the manager of the company says without hesitancy that the locomotive paid for itself in a year, and this statement was made without qualification. The engineer has a man with him who couples the cars, throws the switches and does other work of this character, so it may be said that two men are required to man it, but against the wages of these can be placed the pay of the men who would be used were the cars hauled manually. As the greater experience is had with the locomotive, the better work is accomplished, and as there is but little wear because of the slow speed, the heavy construction and the comparatively smooth track, the management believes that it will be serviceable for many years and be equally productive and is satisfied that it is an economical proposition.

The MOTOR TRUCK

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., OCTOBER, 1913 No. 10

IDEAL CENTRAL STATION SERVICE DEPOT.

New Plant of the Edison Electric Illuminating Company of Boston, Developed to Serve a Territory of 600 Square Miles, and Splendidly Planned, Includes the Best Garaging and Transportation Facilities in America.

By William W. Scott.

WHAT is without question the largest and most carefully developed central station garage in America, if not in the world, is that just completed and occupied by the Edison Electric Illuminating Company of Boston, located on a tract of approximately 12 acres of land in Massachusetts avenue

The Electric Garage of the Boston Edison Company, 236 Feet Length and 110 Feet Width, with Accommodation for 110 Machines, the Finest Service Station in America.

in that city. The statement made applies to the plant as it now exists, but as it has not as yet been completed, and as work on it will continue for a considerable length of time, this article will deal very largely with the garage and the transportation department, and will not discuss the general proposition of a central service station save outlining the plan as a whole, and defining the relation of the transportation department and the station.

The Edison Electric Illuminating Company of Boston was originally organized to afford a general distribution of electric current at Boston, but when the enterprise became well established and the possibilities were realized expansion was conceived. This resulted in the acquisition of different lighting companies in the adjacent cities and towns, the taking over of the plants, and the consolidation of these services, until today the company is one of the largest in America. Boston

stretches southwest from tidewater for a distance of approximately 11 miles. On the north side of the Charles river and across the harbor are Charlestown and East Boston, and including these the greatest length of the city is slightly in excess of 13 miles. The width from the Quincy line to Watertown is not far from nine miles, but the town of Brookline is sandwiched in between the city and Allston and Brighton, so that this distance is more than the width of the municipality.

The Edison Territory.

Radiating in fan-shape from the water front in Boston is what is now generally known as Edison territory, and this includes an area of about 600 square miles, having a population of nearly 2,000,000 persons. Outside of Boston, and the suburbs of Allston and Brighton, the service of the company reaches the cities of Chelsea, Newton, Somerville, Waltham and Woburn, and the towns of Arlington, Ashland, Bedford, Bellingham, Brookline, Burlington, Canton, Carlisle, Dedham, Dover, Framingham, Holliston, Hopkinton, Lexington, Lincoln, Medfield, Medway, Millis, Milton, Natick, Needham, Norfolk, Norwood, Sharon, Sherborn, Stoneham, Sudbury, Walpole, Watertown, Wayland, Weston, Westwood and Winchester, and within this area, as will be noted from the map that is shown, is the city of Cambridge and the town of Belmont. There is a separate lighting company in Cambridge that gives a service to the town of Belmont.

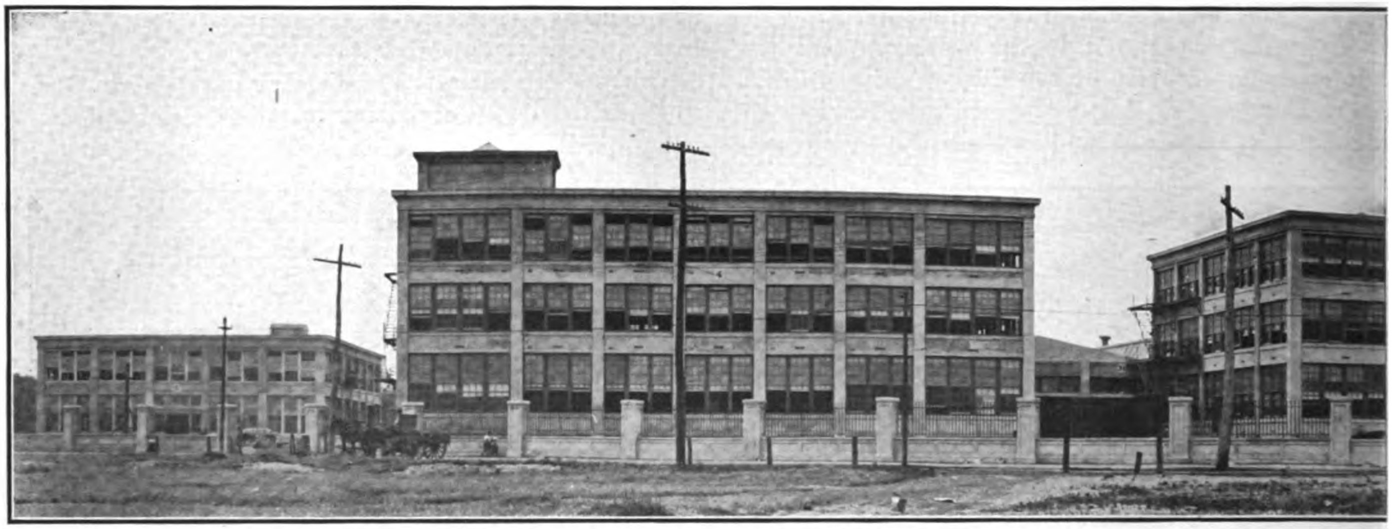
A glance at the map will show the area, as it is indicated by the shaded portions, each town and city being outlined. The suburbs of Boston, Dorchester, Roxbury, Hyde Park, Allston and Brighton are defined within that municipality. Regarding Boston as the centre it will be noted that the Edison territory extends northwest, west and southwest inland, but does not follow the coast save at the water fronts of Boston, Somerville and Chelsea. As a matter of fact the eastern line of the section is nearly north and south, and the extreme western line, which is that of the town of Hopkinton, is more than 30 miles from the centre of Boston. The extreme southern points are those of Sharon and Bellingham, and the southern boundary of the latter is the Rhode Island state line. While a considerable part is north of Boston, the distance to the northern line of Carlisle is by no means as far as Bellingham. The greatest distance between points within the area is about 40 miles, or, to put it more clearly, between the central service station and the extreme point reached by the lighting or power lines.

The Company's Investment.

Within the Edison territory, so-called, the company has property that is valued at more than $30,000,000, this consisting of office buildings, power plants, shops of different kinds, storehouses, pole yards and the thousands of miles of cable and feed wire construction, both underground and overhead, as well as the great diversity of equipment necessary for the maintenance of the systems of distributing the current. This property is maintained at the highest standard.

When the company acquired the different plants and consolidated them it was necessary to follow a policy that was dependent upon circumstances, for centralization was not always economical, that is, to the extent of abandoning property or discontinuing its use, and, of course, the standardizing of equipment or construction could not be hastily decided. But the ultimate purpose was the creation of a system that would afford a constant and certain service, that would be protected so far as possible against such influences as might cause interruption or destruction, that could be expanded with economy, that would require a minimum of upkeep expense, and would be profitable to operate. As might be assumed, the development problem is very large, and this applies to every phase, not only to the distributing system, but to property of every character.

The policy of the company has been to develop substantially, and its property in appearance is such as to always establish the prestige and to impress the observer with the strength and stability of so great and important an industry. The attitude of the company



The Service Depot of the Edison Electric Illuminating Company of Boston, Located on a Tract of 12 Acres in Massachusetts atory, Gasoline and Electric Machine Garage, Covered Drive or Loading Space,

to the public has always been to command respect and commendation, and the welfare of its employees has been given characteristic consideration.

The Administration Plan.

The Edison territory is divided for the purpose of administration purposes, so far as maintenance and construction are concerned, into seven different districts, which are shown on the accompanying map by different shading. One of these consists of the cities of Chelsea, Somerville and Woburn, and the towns of Arlington, Bedford, Burlington, Carlisle, Lexington, Stoneham and Winchester; the second consists of Ashland, Dover (one-half), Framingham, Holliston, Hopkinton, Natick and Sherborn; the third includes Lincoln, Sudbury, Wayland, Waltham and Weston; the fourth is composed of Boston (except Allston and Brighton), Canton, Dedham, Dover (one-half), Milton and Westwood; the fifth includes Bellingham, Medfield, Medway, Millis, Norfolk, Norwood, Sharon and Walpole; the sixth is made up of Needham and Newton, and the seventh of Brookline, Boston (Allston and Brighton) and Watertown.

For operating purposes the districts have separate organizations, each in charge of a foreman, and in each district pole yards are located at convenient places. In connection with construction, work is carried on by another organization, installation being made by the construction departments and up to a definite amount of work by the maintenance department, so that there are three separate divisions that carry on the extension and development, each in harmony with the others, and so systematized that while each has a separate existence the work is never in conflict and expedition and results are always certain.

Demands of the Service.

The company's service is of every character. This means street, building and residential lighting, current distribution for power, heating, cooking, manufacturing, battery charging and any other purpose required. The demand is constant and yet variable. Wherever a customer desires service this is, as a rule, supplied, and it is as necessary to maintain this at the same maximum efficiency at the greatest distance as at the nearest. This can only be done through unceasing supervision and with ample provision to meet any emergency that may arise, for interruption may mean danger to life and property, loss of business by the customer, and dissatisfaction generally, to say nothing of the diminished revenue to the company, as well as the expense for restoration.

Considering the conditions for a moment it will be understood that expansion or development work may be carried on with a view of completion at a specified time, the work of the contract department is with the purpose of affording service at a definite date, and the maintenance department is required to make such renewals and repairs as may be necessary to maintain the service at its normal efficiency. But in addition to this the construction and the maintenance departments must deal with all emergencies and restore the service in the quickest time that is possible.

Avenue, an Ideal Situation for Distribution Over 600 Square Miles of Territory—From Left to Right the Buildings Are: Labor- Temporary Administration Building and Stock House, Storehouse and Power Plant.

In the event of storm, which may damage or impair the overhead construction, cause the flooding of the conduits, the breaking of cables or wires, fires or other happening, it is necessary that the company and its patrons be protected so far as possible, and this means that besides the usual work there must be provision made to instantly begin a temporary or, if possible, a permanent repair or reconstruction of practically any proportion. As approximately 600 square miles of territory must be served with workers and material of any character, it will be realized that there must be means of quick and efficient transportation and of organization for systematically reaching any given point with the least loss of time.

The Transportation Department.

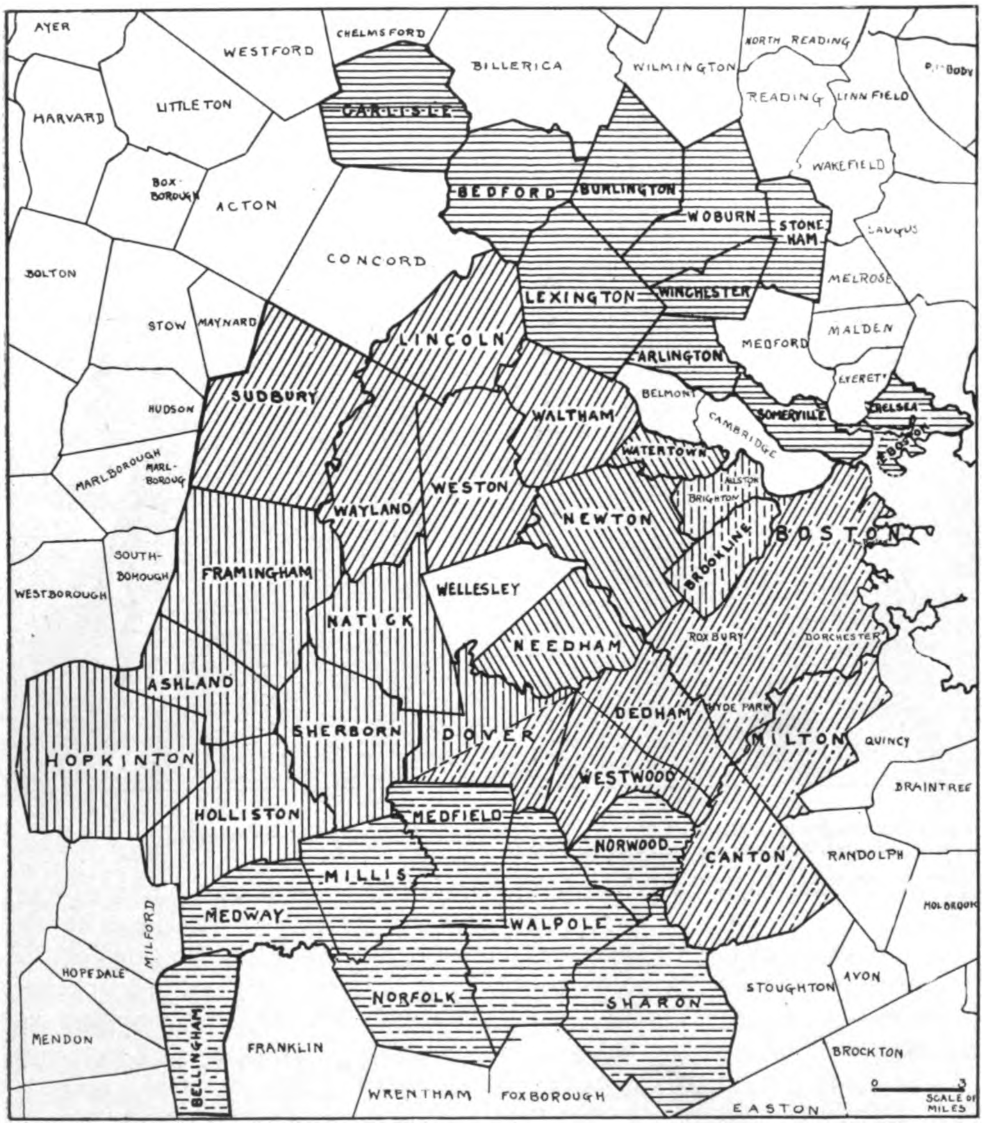
The transportation department is expected to have facilities for every requirement. It is to minimize expense so far as this can be done in the regular or routine work, but when emergency demands the cost is a

secondary consideration. The first result to be obtained is to restore the service. When this has been accomplished economy becomes a normal factor. This necessitates the maintenance of equipment that might not be utilized to its capacity, but a small part of the time, and it is desirable to minimize expense during the period it is not actually in use.

In the transportation work of the company, when it was principally doing business in Boston, horse vehicles were used. Later on freight and express service became necessary, and in emergencies haulage was done direct from the storehouse and shops of the company in Boston. As stated, pole yards were located in different places in the districts and at small stock houses were kept such material as might be required in regular construction and maintenance. This necessitated district organizations for transportation facilities, all under the supervision of the head of the transportation department and yet directly under control of the men in charge of the work in the districts.

The policy of the company was toward centralization, so far as this could be accomplished. With horses it was necessary to have the haulage equipment located where it could be used to the best advantage, for it was impossible to make long hauls save under conditions of great need, and time was a vital factor. In Boston the horses were kept at different stables, and in the towns and cities where equipment was permanently located this was stationed as conveniently as possible to the centres of activities. As the company's territory increased the needs multiplied and the facilities were brought up to the requirements, but creating a condition that was keenly realized.

The company purchased its first motor vehicle in 1903, and with the increased use of this form of equipment and the greater knowledge of the conditions with which the company had to deal, a careful study was made of the transportation problem that, with the definite result of observations, developed a plan that is now in part realized. The magnitude of the proposition may be understood when it is known that nearly three years' time was necessary to construct the plan, and more than a year has been required to execute it to a point where its benefits are obtained. But while a considerable period must elapse before the plant as it is planned will be complete, there is every probability that it will be in a state of transition for many years, for it will be expanded as the needs of the service are manifested.



Map of the Towns and Cities Served by the Edison Electric Illuminating Company of Boston, the Shading Showing the Area of the Territory, and the Difference in Shading Lines the Seven Districts Into Which It Is Divided for Administration Purposes.

The executives of the company approved a plan, and then began the constructive work. Briefly, this plan comprehends the following: A service depot which includes a power house, store house, stock house and shops, garage and a laboratory, together with such other buildings as may be necessary from time to time, as well as a structure given over to the welfare of the employees and such provision as may be desirable for their comfort and convenience. In connection with this is to be maintained sub-service depots for the construction and maintenance of lines departments, and in the further removed sections subservice stations for all the service departments.

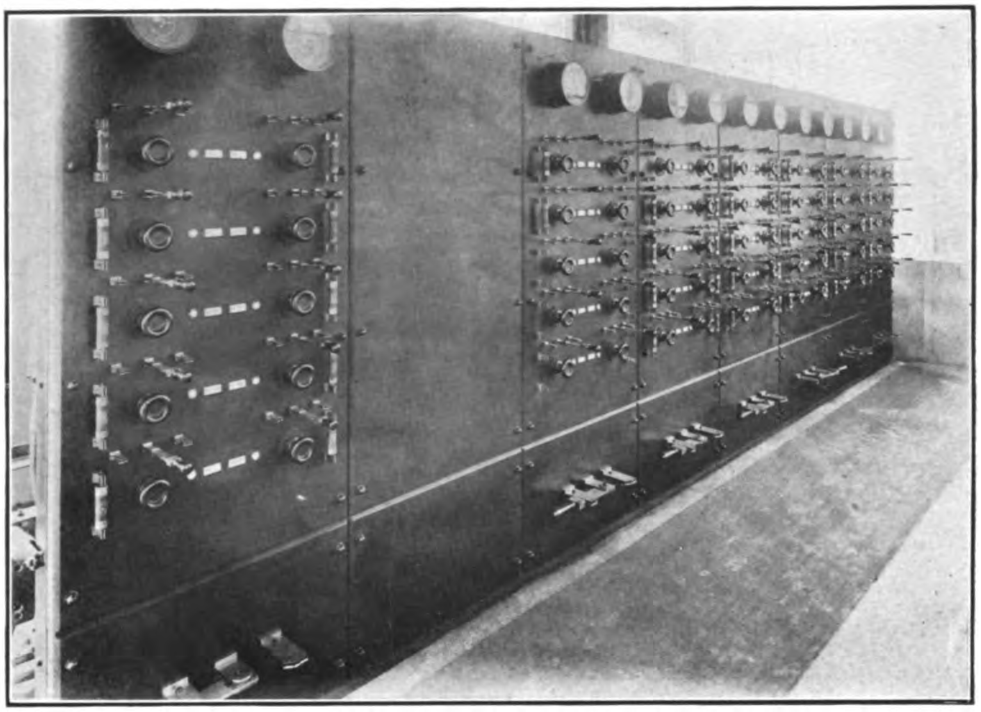
Massachusetts Avenue Plant.

The company purchased a tract of approximately 12 acres between the tracks of the New Haven railroad

and Massachusetts avenue, in the extreme east side of the Roxbury section of the city, close to what is known as South Bay. On this was begun the erection of a series of buildings of reinforced concrete. These are in order, from south to north (and as seen in the illustration from right to left), the power house, the storehouse for heavy materials, general offices, the shops and the stock room; in the rear, the covered driveway and loading platform, the gasoline and electric garage and the laboratory. The property is roughly triangular in shape, and the buildings are located in the apex, close to the New Haven railroad. The structures as built, aside from the laboratory, are in line with reference to the frontage, and stand at an angle from Massachusetts avenue when viewed from that highway. Between the buildings and the street, however, is a considerable area, and this will, if demands justify, be available for the expansion of the plant. The original plans had this provision for possible increase, which will indicate to what extent the future has been anticipated.

These five buildings are the beginning of a group that may eventually cover the entire property, or so much of it as can be built on. In addition to these there is to be constructed within a comparatively short time welfare buildings, which will be removed somewhat from the others for obvious reasons. This article deals with the plant but incidentally aside from the provision made for the transportation department, and the shops, storehouses, power house and the laboratory will be passed over with briefest description. From the viewpoint of the central stations these buildings, however, are exceedingly important, and if space would permit would be worthy of detailed attention.

The advantages of the centralized depot are manifold. It is located on the direct line of the New Haven railroad, from which spur tracks extend to sidings, where cars may be received or sent out and a small train of cars can be cared for on the siding and in the yard, making the receiving and shipping by freight almost ideal. The depot is but a short distance from the freight yard and cars may be sent out or brought in quickly in the event of car shipments. The depot is convenient of access from all parts of Boston and vicinity for haulage, being accessible by Massachusetts avenue from the southern, western and northern sections, and by Albany street from the business section of the city. Between the railroad and the buildings is a large reservoir, that is for fire protection in the event of damage or destruction of the usual service water mains of the city, and a large pump will afford ample pressure for a special yard water supply, which can also be used to supplement the city service. The buildings are sufficiently isolated so that there is little probability of a fire in that part of the city ever reaching them, and the construction is fireproof so far as science has proven is practical. Back of the buildings is a large area that may be used for railroad tracks and open air storage, and incidentally provision will be made for recreation grounds for the employees. There is a very good trolley service, so that the plant can be reached readily by the workers. All of these factors were carefully considered in the plan, and there was a distinct purpose in practically every detail decided on. It is also desirable to mention that practically all of the buildings can be materially increased in proportions by the building of additional stories on to them.

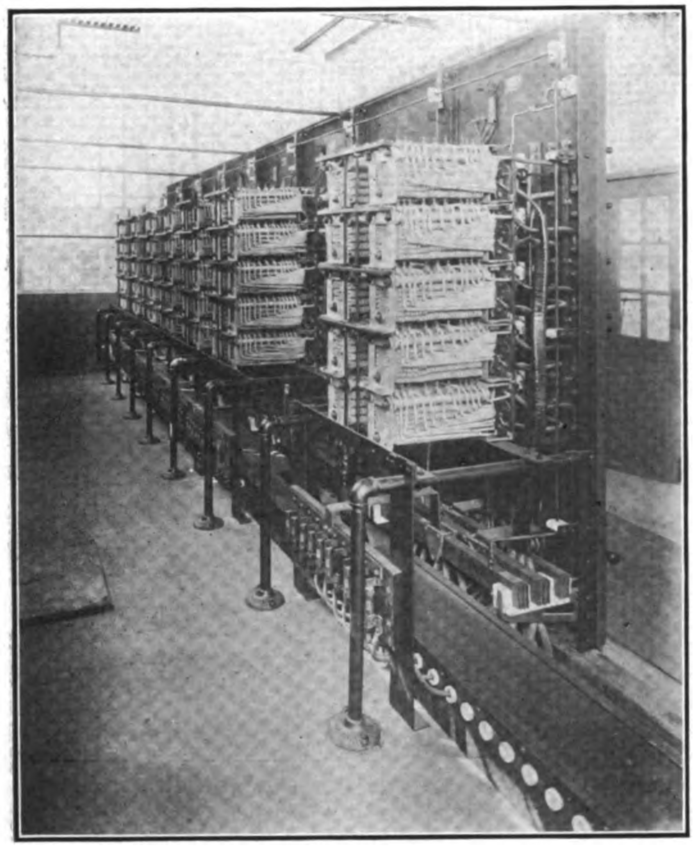


The Switchboard in the Battery Room of the Electric Garage, Showing the Variable Voltage Switches Near the Bases of the Panels, and the Numbered Indications of the Circuits and the Vehicles Charged on Them.

Considering the buildings separately. At the extreme right from the front of the plant is the power house. This is provided with boilers for heating and with three motor generators sets, two of 200 kilowatt and one of 50 kilowatt capacity, and these may be used independently or collectively, affording both power and heating. The equipment is the best that can be procured and the installation is made with the purpose of securing the greatest economy and service. At the extreme left of the present buildings is the laboratory. This structure is now approaching completion and it will have the finest of equipment for testing and developing electrical apparatus. A finely fitted photographic studio is located in the second floor, as well as a photometer room designed for light testing. The laboratory is a department of prime importance and

everything essential or desirable will be provided.

Between the power house and the laboratory are located, from right to left, the storehouse, the stock house and shops, and the garage, the latter being a combination building for both electric and gasoline machines. The storehouse is a single-story building, in which is the shop of the maintenance department, this being fitted with such machine tools as are necessary for alterations, changes and repairs, and equipment for testing machines of different kinds kept in stock and utilized for regular installations. Here, also, are kept the heavy cable and wire, the material of different kinds required in construction and maintenance work, with floor cranes and electric trolley cranes for handling heavy units. This division is departmentalized and the divisions are by heavy gratings. The building is protected from fire by a sprinkler system and it is well heated and lighted. Between this building and the stockroom is a drive with numerous doors so that each department can be reached conveniently from it.



Back of the Switchboard, Showing Its Accessibility, the Double Set of Bus Bars, the Terminal Conduit and the Quickly Removable Resistance Units.

The third building as it appears in the illustration is of three stories, and this is used for the present for administration and general office purposes, but later on this will be devoted to other uses, in part at least. The three-story portion of the structure is 110 feet frontage and 80 feet depth, and back of this is a single-story building, with basement, 110 feet width and 236 feet length. Entering this from the front, at the right are the shops, where the lamps, meters and general equipment are examined and tested before being used or previous to placing in stock, and at the left are the stockrooms, in which in bins and compartments are kept all lamps, meters and material of all kinds used in light construction and installations. In the basement stock is stored and from this the supplies in the different rooms are replenished. At the rear end of this building is a stall that will hold the largest freight car. Into this stall extends a spur track. A lift bridge affords passage across the stall when it is not in use. The floor of the building is level with the floor of a car on the track. A car can be unloaded under shelter and the contents sent to the basement by chutes. In the stall a car can be quickly loaded or unloaded and with no possibility of the contents being damaged by storm or handling. This stall serves as a garage for an electric locomotive used to handle the freight cars in the yard or on the siding, and there is a charging outlet and plug by which the locomotive battery may be charged at night or given a boost by day if this be needed. With this locomotive the company can handle its cars independently of the railroad, and the combination stall simplifies the problem of sheltering the equipment and handling the freight.

The Garage Facilities.

The building at the left of the stock house is the garage, which is in two sections, the three-story part seen in the illustration, and a single-story construction behind it. The picture shows a continuity of structure between the two three-story sections, and this is the end of the roofing over the drive between the buildings. While this is a drive in the use made of it, it is also a loading shed, and with comparatively little change it could be made to serve for additional garaging purposes. The two buildings are 70 feet apart, and over this space, 236 feet long, stretches a modified monitor roof, supported by trussed girders, without a post or obstruction, with end walls in which are three entrances. These entrances can be closed by doors and the entire loading shed kept at a reasonable working temperature in the coldest weather.

The full length of the stock house side of the drive is a loading platform at the floor level, and at the height of the wagon or truck body floor, that is 10 feet in width. The drive itself is paved with brick paving at such inclination as will insure drainage, and it can be flushed with hose when cleaning is desired. On the loading platform and against the side wall of the stock house is a series of steel lockers with doors of heavy grating, and on each of these is the number of a vehicle. In these lockers are placed packages and materials taken from the stockroom as the orders are received during the day and so a portion of the loads is practically made up during the absence of the vehicles, and the loading time of the drivers and the machines or wagons is decidedly reduced. The lockers will not contain a vehicle load, but in them all small orders can be placed. The large packages are made up and left in the shipping room ready for the drivers. This system gives each vehicle a loading place at the platform, and as 45 can be loaded at one time this eliminates confusion or uncertainty and very greatly econ-

omizes time. Doors give access to the platform at frequent intervals and handling is minimized. With these facilities loading may be done in practically the same time during winter or summer, and an enormous volume of freight can be handled during a day. The loading shed is well lighted by day or night, and with three entrances from the street end there is neither delay nor confusion in entering or leaving.

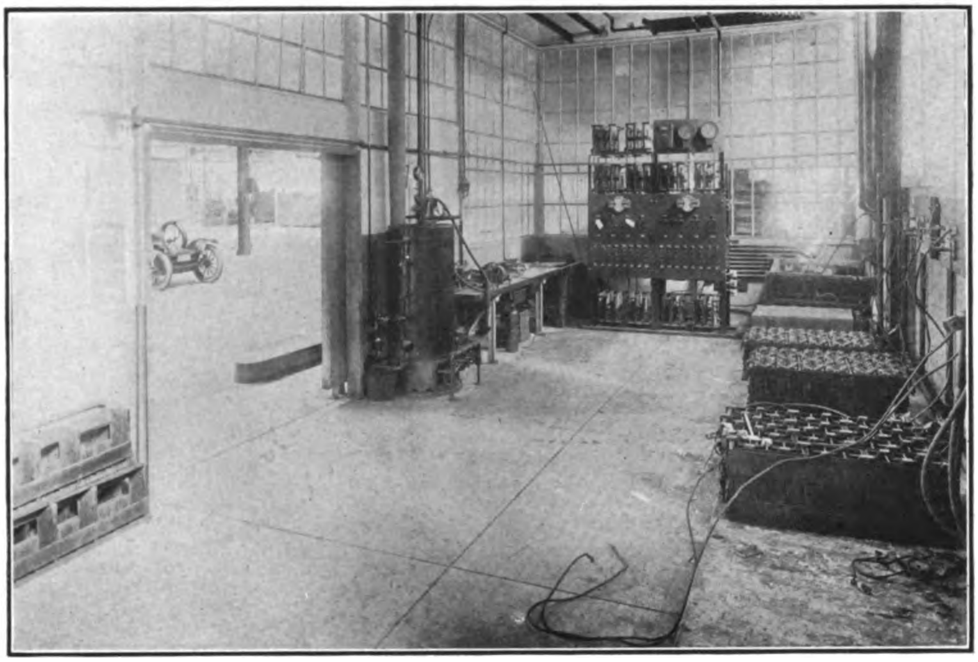
Provision for Gasoline Machines.

The garage building is 316 feet length and 110 feet width, and has a floor area of approximately 52,360 square feet. The three-story section is separated from the single-story portion by a heavy fireproof wall that is in line with the end of the loading shed. The end seen in the illustration is given over to the garage for gasoline machines and the repair shops, and the floor area is 80 by 110 feet. The rear part is the garage for the electric vehicles and is 236 by 110 feet. As stated, the construction is reinforced concrete with a large part of the gasoline garage walls made up of windows, making the interior extremely light, and greatly facilitating the work done during the day. In the centre of the end nearest the laboratory is a tower that contains the hoist for the mammoth electric elevator, 22 by 11 feet, that serves all three floors. The concrete floors of the buildings are supported by large pillars of the same material.

This building has no basement and the entrance to the main floor is in the centre of the end at the main drive between the garage and the administration building, and aside from the office of the head of the automobile division, an oil room and a passage to the electric garage, and the walls that enclose the iron staircase to the upper stories, the main floor is clear for the storage of vehicles. In the centre of this floor is a washstand, drained from the centre, with gang lights that may be placed at any height to permit the washers to have the best of light and on any part of their work desired. In this section is a 300-gallon water tank, suspended from the ceiling, that is heated by electric energy, from which hot water is available, when the boilers in the power plant are shut down, in any reasonable quantity. The oil room contains three portable measuring tanks lined against a wall, which may be filled from a carrier on which a barrel may be raised from the floor and drained into any given tank. The room is protected by fireproof glass windows and walls, and in the event of need the tanks may be removed to safety almost instantly.

Half the second floor of the building is given over to storage of cars, and this section has a washstand with similar lighting; a room for the drivers to lounge in while on or off duty, a lavatory, a shower bathroom, a locker room for the drivers, a room fitted with storage and drying racks for robes and similar equipment, and a dormitory of four rooms furnished for the use of the car dispatchers. The third floor contains at one side of the elevator shaft the stockroom for parts and material and the machine shop, the shop being equipped with lathes, presses, grinders, shapers and other machine tools.

This equipment is such that practically any work can be done that might be necessary in repairing, overhauling or rebuilding a gasoline or electric vehicle. On one side of the floor all of the overhauling is done, there being space for eight vehicles side by side. Along the wall is the work bench with ample space for the workers. The centre of the floor is clear for moving the



The Battery Room, Showing the Concrete Platform at the Right, the "Hospital Board" for Test and Experimental Work, Fitted with Recording Meters, the Workshop and the Steam Boiler.

vehicles. Two portable cranes are part of equipment.

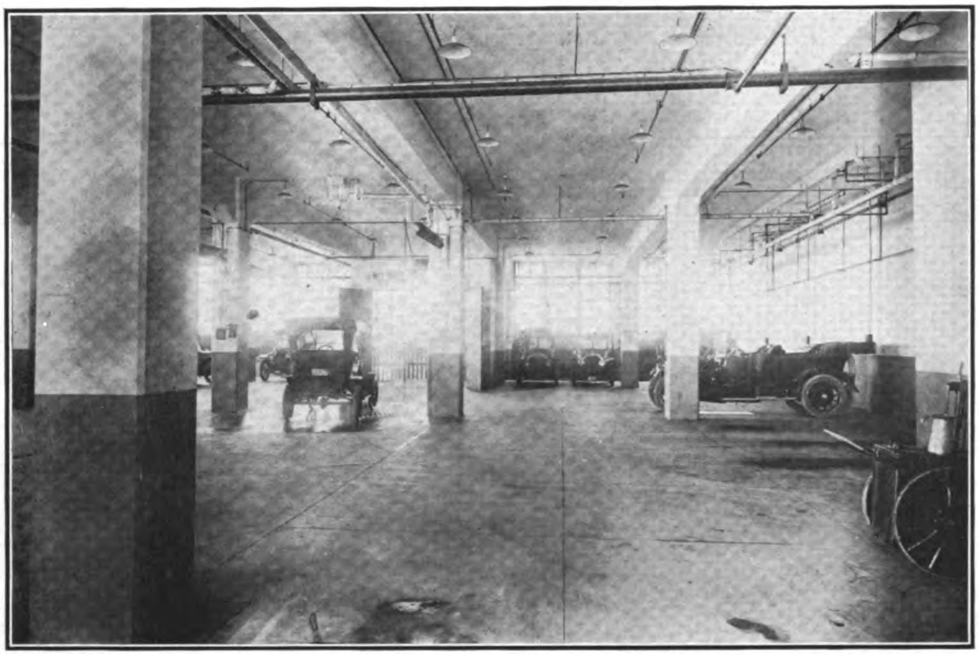
At the other side of the building in the place of the stockroom and machine shop is the blacksmith shop, which is isolated from the remainder of the floor and communicates with a passage open to the air, and there is a pickling room where parts are given a hot potash bath for cleaning, overhead trolleys and chain hoists making for easy handling. This room also communicates with the open air. The purpose of the open air communication is to eliminate all possibility of explosive vapor accumulating. The repair department is arranged as is the overhauling section, and with every facility for the workers. Besides admirably designed heating and ventilating systems the workmen have a large washroom and a lavatory. One of the features of the shops is the lighting, it being equipped with fixtures so that light can be so centred on any part of any

work that there is even better illumination by night than by day. On this same floor is the paint shop and the varnish room, both of ample size.

The garage is a model from every point of view and is planned to store 50 machines with sufficient space about them for work and attention. Every facility that will simplify the work, safeguard the property and contribute to the welfare of the employees has been adopted. One of these is an automatic door to the main floor that can be opened or closed by pressing a button in the office, which is done at a horn or bell signal from the driver. The gasoline is supplied from a large tank buried outside of the building. With the isolation of the lubricating oil tanks there is practically no danger of any kind from fire, but the building is provided with a very complete sprinkler system and with standpipe and hose, as well as with hand extinguishers for protection.

The electric garage is a single floor of practically 26,000 square feet, covered with a roof supported by trussed girders and two lines of angle steel columns. These columns are at frequent intervals and the aisles between them, the length of the building, are approximately 16 feet width. Entering this through the door from the gasoline garage the right wall is broken at intervals by doors to the drive between the building and the stock house. The doors are hinged at the top and are balanced so that they may be raised or lowered with practically no effort and almost instantly. At the left side of the floor, about midway its length, is the charging switchboard and the battery room. These are enclosed by concrete and glass partitions, the glass being largely of fireproof construction. Between the sections housing the switchboard and the battery room is a fireproof partition.

The roof is built with several sections of fireproof glass so that, with the windows at the left side and the end, and the doors at the right, the lighting is admirable by day. The floor is concrete, with four large wash stands that will each accommodate two machines. This floor may be flushed with a hose to insure cleanliness. The heating is by steam with radiation from wall piping. At the walls, at the side, between the doors and at the end, and located on the angle steel pillars, are the charging stations, 110 in number, and these are designated by two numbers. The circuit number corresponds to the circuit number on the switchboard, and at each station, suspended over the vehicle space, is the number of the machine assigned there. Each vehicle number is also posted with the circuit number at the switchboard, so that the charging operator may know at a glance the vehicle being charged or served by any particular circuit. In combination with each station is a wattmeter, that registers the volume of current supplied to each vehicle in charging. Between each door at the side and on each post are four stations, each of which is operated by a knife switch. Overhead the girders carry the lighting and the sprinkler systems.



Section of the Ground Floor of the Gasoline Garage, Illustrating the Location and Equipment of the Washstand, and the Lighting and Fire Protection Installations.

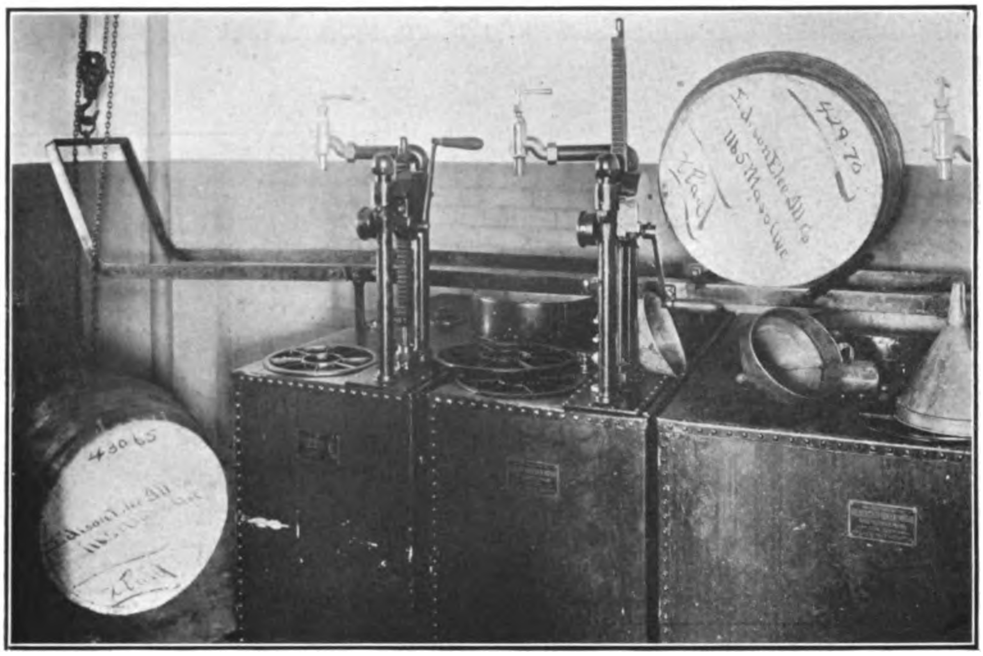
The Charging Facilities.

The switchboard room floor is elevated above the garage floor and on this is placed the board, which consists of eight panels, seven of which are now in use. The circuit lines are under the floor in conduits and are carried from a terminal conduit through porcelain outlets and are connected with the board. The connection is made with a bus bar through fuses that are in plain view, as may be seen from the photograph of the rear of the board, and each circuit is numbered plainly so that it may be located at a glance. The terminal conduit is built to permit a considerable extension of the board without additional construction outside of the installation above the floor. The board is practically in the centre of the floor, with a wide space behind it, and frames carry the resistance, which is so installed that any section may be removed at will without affecting any other part of the board, and any portion is as accessible at the back as at the front. The value of this construction is apparent and will undoubtedly result in a great saving in time.

It will be seen there are four bus bars in the switchboard, and this is accounted for by the fact that the board has two separate circuits which have two separate voltages. The change from the low voltage to the high, or vice versa, is made by throwing the heavy knife switch that is shown near the base of each panel in front. The low voltage circuit is what may be termed normal at 90 volts, but this may be varied at

the power house from 70 to 100 volts, and the high circuit, normal at 130, may be similarly varied from 90 to 140 volts, so that the range of voltage may be as much as 70 volts when necessary, and adapted for any particular service.

This voltage may be varied with reference to any panel, and as the circuits are grouped to the panels for the classes of cars to be charged, variable voltage, from one extreme to the other, may be provided on two adjoining panels. The variation in voltage is secured at the power house by varying the field resistance of the generators. By this construction it will be seen that the line resistance and the battery resistance can be overcome and high voltage secured whenever it is needed, and when high voltage would mean a large loss in the rheostats it may be changed to a lower rate and this in turn varied to as low as 70. The value of this construction is in the large saving in current, which economy can be understood by all electricians, especially when the number of batteries to be charged is large. This may be explained more clearly by stating that when a line has a voltage of 115 volts, for instance, there may be line and battery resistance that lessens the actual charging voltage to perhaps 110 or 109. When a lesser rate is desired this is secured by the rheostats, and though the full line voltage is used, a part of the energy, in excess of the voltage used in actual charging, is lost or consumed by the heating and consequent radiation of the resistance.



The Lubricating Oil Room, Equipped with Hoist and Carrier for Handling Barrels, and Quickly Removable Measuring Tanks.

The switchboard construction and the manner in which the details have been worked out can only be referred to briefly in this article, but it will be understood that when the garage has a capacity of 110 cars, with the voltage requirements varying greatly, and with machines with batteries of numerous types, the advantage of grouping them with reference to charging, and of minimizing current loss, means a very large economy in the course of a given period as compared with charging through a line of fixed voltage.

The Battery Room.

Of about the same size as the switchboard room is the battery room, and especial attention is directed toward the illustration of this department, which shows the construction of the partitions, insuring ample light, as well as the provisions made for work. In this picture is seen at the right a concrete bench for the batteries, where they can be worked on conveniently and where they can be charged from outlets located on the wall. This bench will take a dozen batteries side by side and all can be worked on at once if necessary without crowding the workers.

At the further end of the room is what is known as the "hospital board", which is a charging panel of two sections, each carrying a wattmeter, a voltmeter and an ammeter, the last two being of types that make chart records. With this it is possible to take a battery that is faulty or defective and by means of the charts note all the characteristics in charging and discharging, make any tests or experiments, and make comparisons to determine what work is necessary to restore normal efficiency. By this, also, it is possible to make tests from time to time of batteries and ascertain the degree of lessened capacity. The general purpose of the board is to ascertain absolutely certain records, which are regarded as far more satisfactory for experiment, development and reconstructive work than any other method, especially where so large an investment is made and where efficiency so greatly depends on the serviceable condition of the batteries.

At the left side of the room is the work bench and the boiler, the latter being used to generate steam with which to cleanse the Edison batteries of the accumulations of encrusted potash. This steam is used under pressure and is worked with a hose. At the other end of the room is a stock department with a number of open bins, a water still that will produce 300 gallons of distilled water daily, and a small charging panel where a single cell to 10 cells can be tested, charged or discharged, the generator working as low as one volt. The rooms below the windows are of fireproof material and the floors can be flushed and kept clean. The doors of the battery room are a sliding type, while those of the switchboard room swing and are kept closed by spring hinges.

The garage is equipped with a thorough fire protection service of standpipes, hose and fire extinguish-

ers in addition to the sprinkler system. Close to the switchboard room is an air compressor that affords a constant pressure of 90 pounds for cleaning and tire inflation. There are two entrances through the rear end wall to the grounds independently of the drive. As may be assumed, the vehicles are taken from the garage directly to the loading platform, and there is no possibility of delay so far as the service depot is concerned.

Motor Vehicle Equipment.

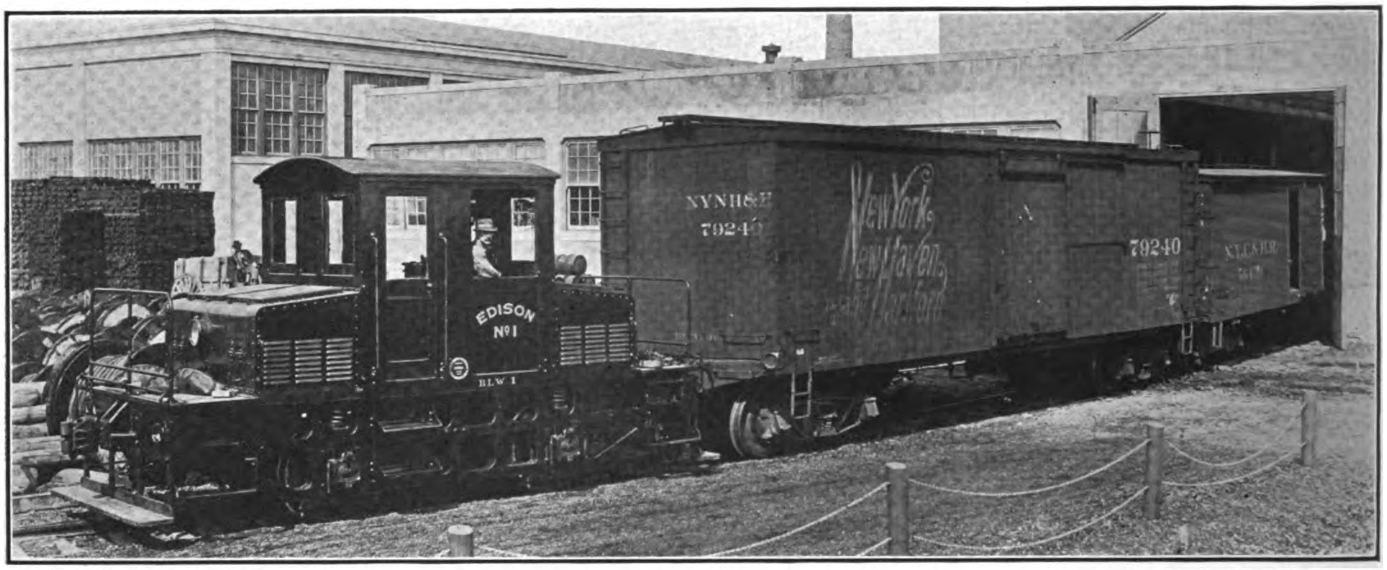
The equipment of the company now consists of the 110 vehicles in use and 33 on order, some of which may have been delivered since this article was written, so that the total that will be in use in a very short time will be 143. Taking up the electric machines first, these include 17 700-pound wagons, 10 1000-pound wagons, one 1500-pound wagon, five 2000-pound wagons, one 3000-pound wagon, two 4000-pound wagons, one 3.5-ton truck, one 10,000-pound truck, one 12,000 pound truck and 22 two-passenger cars. Orders have been given for 11 1000-pound wagons, two 2000-pound wagons, 11 4000-pound wagons and a four-passenger car, this making a total of 60 machines at work and 25 ordered, a grand total of 85. The gasoline equipment consists of one 1500-pound wagon and two 3000-pound wagons in service, and one 3000-pound wagon ordered. The company has 37 different cars in use and seven ordered, making a total of 50 in service and eight ordered.

Of these machines 71 electrics will be kept at the garage and 11 wagons, five 700 pounds, one 1000 pounds, one 1500 pounds, four 4000 pounds and three two-passenger cars will be kept in outside garages, and one 1500-pound gasoline wagon and 12 gasoline cars will be kept outside, and 42 gasoline cars and three wagons will be kept at Massachusetts avenue. The total kept at the garage will be 116, and the capacity is 160, so it will be seen there is ample room for expansion without crowding or congestion in any of the departments.

Machines Garaged Elsewhere.

The fact that 27 machines, 12 of them wagons, are, or will be, kept outside of the garage, may require explanation. In view of the facilities and economy of the central depot the supposition might be that all vehicles would be kept there, but when the area of the territory is realized and the needs of the construction, maintenance and contract departments are understood, the reason for having these wagons and cars stationed in the districts, where very valuable time may be saved, is apparent. These vehicles are kept at garages where they are ready for service and may be reached very quickly at such times as they are not in use. These machines are handled by regular drivers, who may be considered on call at all times when off duty, although in the event of need others may drive. The vehicles are in some instances long distances from the service depot, and quite as essential as the carrying of material, supplies, etc., is the possibility of supervision, for men in charge of work can direct gangs working in different places and decidedly economize. Were it necessary to send the materials each day from Massachusetts avenue a great deal more mileage would be required, and unless men were stationed in the districts, with machines for travelling where the transportation facilities are by no means as satisfactory as in the city, it would be impossible to have the desired oversight without a considerable increase in men. For these reasons the number of passenger machines is seemingly large.

There is no reason to believe that the company will have small garages in the different sections where machines are kept, for such a policy would require too great expense for the service. It is probable that the system will be continued as outlined, and the service garage fleet will be added to as required. But the additions in the districts will be single vehicles as a rule, and there will be no further endeavor to centralize the equipment. Incidentally, mention should be made that the company now works 90 horses, principally in



The Electric Locomotive Used for Moving Freight Cars in the Yard of the Service Depot and on the Sidings That Are Near the Plant.

Boston, and 25 of these will be disposed of when the machines on order have been received. The expectation is that the entire equipment will soon be motorized.

The first motor vehicle equipment of the company was a Columbia electric runabout, that was purchased in 1903, and the following year five electric machines were added, these being a 1000-pound wagon, a 2000-pound wagon equipped with a pump driven by a gasoline engine for pumping water from manholes, a three-ton truck and a five-ton truck, the latter being fitted with winches for hoisting and heavy work. The company then boarded all its horses in stables in several parts of the city, and when the electric machines were bought the company established an electric garage at 516 Atlantic avenue, which was later transferred to the jurisdiction of the committee of the Electric Vehicle Club, and subsequently turned over to the Electric Motor Car Club of Boston, and conducted as a public service station.

Because of the limitations of the electric garage and that the company deemed it advisable to segregate the gas and electric machines, a garage for gasoline cars was established in Stanhope street, but later this was increased in size and the electric machines were kept there after the transfer of the Atlantic avenue garage and pending the construction of the Massachusetts avenue plant.

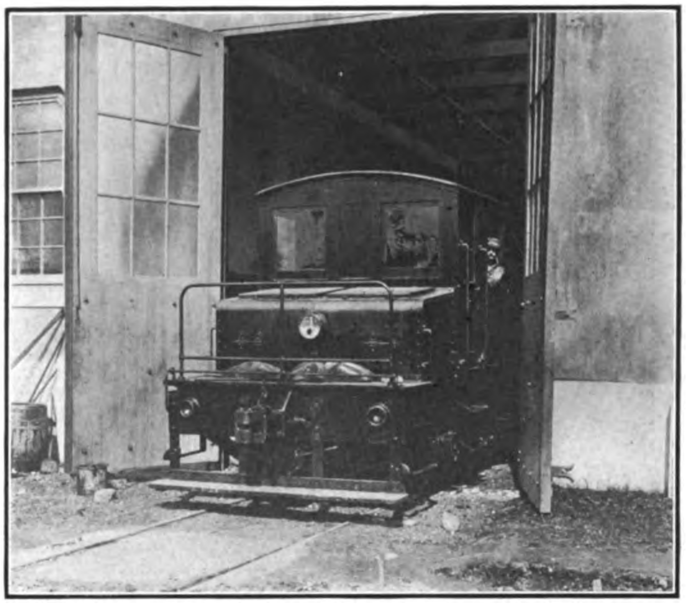
How Machines Are Utilized.

The system of the company as indicated by the map shows seven district organizations, and as stated these have pole yards conveniently located for the distribution of the poles. Up to a radius of approximately 10 miles the distribution of stock, material and supplies required for construction and maintenance is delivered by machines daily from the Massachusetts avenue service depot, but beyond this the deliveries are made periodically to the sub-service stations for the construction and maintenance departments, and still further out to sub-service stations for all departments. In the routine distribution the wagons have regular trips that are covered daily, these serving the outlying districts with supplies, but all emergency requisitions are filled by special trips. The meter wagons are required to make regular trips, each having such assignments as will constitute a day's work, and where occasion requires additional wagons or trucks are hired to do work in excess of the capacity of the regular equipment. In the event of the haulage being done by railroad the cars are loaded in the yard, hauled to the siding and the railroad notified.

All the haulage of supplies, express or freight receipts or shipments, is work done by the teaming division, so-called, of the transportation department, and the handling of the freight cars is also included in the work of this part of the organization. The haulage for the different departments, aside from that specified, is done by the different departments by vehicles that are operated by the transportation department, but this service is charged at definite rates to these departments. Wagons are assigned to different departments and are under the jurisdiction of the heads of each, but are maintained and their service is practically contracted for with the transportation department, so that the departments bear the expense of whatever work is done by these vehicles.

The Operating System.

In explanation of the system it should be stated that when a department requires a vehicle application is made to the purchasing bureau, and after the proposition has been considered by the heads of the department, the purchasing bureau and the transportation department the purchase is authorized. The vehicle is then assigned to the department and is charged for at a fixed daily price, which may or may not include the wages of the driver. Drivers having work of this character take their orders from the department heads and not from the transportation department. Such work may be for the lamp department, meter department, for the use of trimmers, for patrol duty, and the like, or for the use of the officials and engineers. The charge made for the use of a machine includes all operating expense and driver's wages and the maintenance and fixed charges, including depreciation. If an extra vehicle is provided at any time this is charged at a daily rate, but in the event of withdrawal from service for any cause the replacement is charged at the averaged cost. If an extra trip is made this is charged at an hourly rate. It will be seen that wherever possible the department is charged specifically, and only where this cannot be done is a general charge made.



The Stall in the Stock House That Serves as a Garage for the Electric Locomotive and Unloading or Loading Platform for Freight Cars.

As stated, all motor vehicles are under the direction of the head of the automobile division. All machines purchased are those that in the opinion of the superintendent of the transportation department are best suited for the requirements. If a driver is supplied by the department he is carried on its pay roll, and is under its control, but a driver may be employed

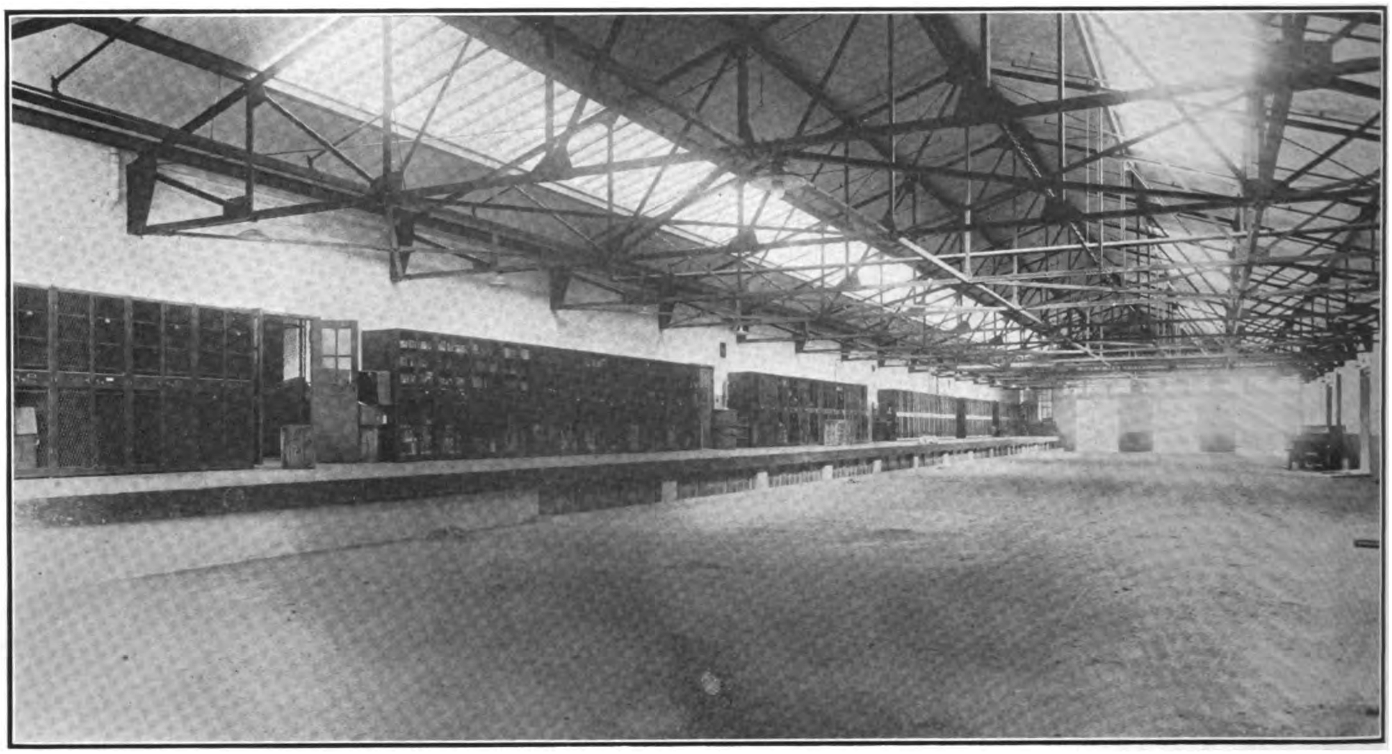
and controlled by the department in which he serves. When a machine is purchased the detail of it is entered on an inventory card that is placed in a perpetual file. Record of the machine is entered in all the forms that may be required of it, and these are carried until the vehicle is disposed of.

Dispatchers and Drivers.

The operation of the division is directed by the head of that division, who receives his instructions from the superintendent of transportation. In the garage is stationed the car dispatcher, who is on duty eight hours at a watch, and there are three watches, so that a dispatcher is constantly at the switchboard, with four men doing this specific duty. Each dispatcher is a thoroughly experienced driver, and should there be a call and a driver is not instantly available, a call is made for another dispatcher, and the man on duty calls a garage man to take his place temporarily and he will take out the car that is called for. The dispatchers have a dormitory in the garage and each man is on duty 16 hours daily, eight hours at the switchboard and eight hours on call, to insure against any emergency. In the event of a fire or any need for the attendance of any special men cars are sent out instantly to rush them to the place where their presence is required, their cars being used if they are available, and other machines if they are not. Notification is given the general manager and his instructions are carried out, besides the usual requirements of the organization. The car dispatchers have important work and the switchboard cannot be left unattended. Besides providing machines for the officials and others when an emergency call is received, drivers are notified, and the entire transportation department's force can be summoned with great rapidity. The dispatchers in the course of routine work direct the drivers so far as ordinary needs are concerned, giving the orders received from the superintendent or the different department heads.

The drivers report at the garage for daily duty and on taking out their machines stamp a time card in a clock for themselves and one for the machine, so there is a record of both vehicle and driver. When instructed to do so the drivers report by telephone, but otherwise they complete their work before returning. On arrival at the garage the driver and the vehicle record is again made on the cards. The card records are in addition to the entries made when the machines are taken from or returned to the garage, such entries being required by law.

On the arrival of the driver or user of a machine at the garage report is made of the condition of the vehicle, the assumption being that it is satisfactory in operation in the absence of statement to the contrary. But the washers, polishers, oilers, batterymen and others working on the cars and wagons are expected to make report of any condition that may require work to insure serviceability. Should breakage, wear, loss or any other cause require attention, report is made to the garage foreman on a repair tag, on which the precise condition is stated and placed in a special rack. The superintendent usually sees these tags, but the foreman takes them, inspects the vehicle and then assigns the work to a man or men if it can be done in a single night and the machine made ready for service the next day. What are known as "repair" jobs are done by the night force of men in the repair shop, and the overhauling and large repair jobs by the day shift,



The Splendid Covered Loading Platform Between the Electric Garage and the Stock House, 10 Feet Width, on Which Are the Load Lockers—The Drive Is 60 Feet Width and 236 Feet Length, with Closed Ends, Each End Having Three Entrances.

so that the shop is always busy and men are on duty constantly, six of them at night. On the repair tag is noted the usual information with detail of the time required and the materials used.

Should there be a road accident of any kind that will prevent the operation of a machine the report will indicate what is required. If a road repair can be made a mechanic with the necessary tools is sent out. If spare parts are required these are taken. If the vehicle can be made operative this is done, but if not such work is done that it can be towed to the garage. If necessary the load is transferred. An emergency wagon is always in readiness for calls of this kind and men are available from the garage or the repair shop.

When a machine is withdrawn from service for overhaul another replaces it and usually two weeks' time is taken to practically renew a vehicle and restore it to first class condition. But if an old car, wagon or truck that is to be replaced by another, such work is done as will make it saleable. At regular intervals the machines are inspected, both in the garage and on the road, the last work usually being done on vehicles that are stationed in the districts and are not often in the garage. The reports usually determine the overhaulings.

The district service cars and wagons are given attention in the garages where they are stationed. Daily readings of the odometers and daily charging reports are sent in to the head of the automobile division, and daily oiling records are also kept.

In the daily work on the machines, washing, cleaning, polishing, replenishments of fuel, water, oil, electrolyte, supplies used, such as waste, alcohol and the like, record is kept of the supplies drawn from stock and, so far as is practical, used for each vehicle. The miscellaneous labor on the automobiles in giving the care and attention in the garage, as well as the materials and supplies, are computed and the expense divided pro rata.

The System Summarized.

Summarizing the system of administration: The machines are charged to the department at stated prices, inclusive or exclusive of the driver's wages. In the event of repair the job cards show the time and material used for the job and after being figured by the garage clerk they are sent to the clerical division for entry in the journal. The cost of each repair is figured on the job card, the time of starting and finishing the work being shown by the time clock stamps.

All supplies are drawn from stock by requisition which, after being priced, are entered in the journal against the machine on which the supplies were used. Some of the supplies and expenses, such as oil and waste, repairing tubes, labor of washing and polishing, etc., are charged to general accounts and pro rated at the end of each month. Whenever possible, however, each item of expense is charged directly on the journal to the account in which it is carried and against the vehicle for which the expense was incurred. The journal is a loose leaf book with a number of sheets for each machine equal to the number of accounts shown on the car ledger. At the end of the month the journal is footed and the totals carried to the ledger for that specific month, and the departments are charged as the accounts require.

The records show a form for the tire, which is filled when the tire is purchased and when a tire is installed the record will show the vehicle and the serial number branded on pneumatic shoes, or the wheel numbers if the tires are solid. The records include what may be termed a history of the tire, that is filled from time to time from the date of withdrawal from stock to the date of disposal. The garage record differs from the office record in that it deals particularly with the service. Both the garage and office records for tire adjustment show detail facts that are essential in working out the eventual cost of service, which is kept for each mile for every tire used.

For the exact information of the reader the forms used by the company in its transportation department have been reproduced on a special insert sheet and these are numbered in approximately the order in which they are used in the records. The numbers on the forms, however, are for the benefit of the reader that he may readily find that which he may seek, and these numbers correspond with the numbers given in the brief explanation of each that follows. These forms are practically self-explanatory:

Description of Forms.

When a vehicle is required for use in any department of the company a request is made to the purchasing bureau of the company by the head of the department, and if this is necessary for continued use an authorization for purchase is made out and submitted by the purchasing bureau to superintendent of transportation, and when this has the approval of the department, the purchasing bureau and the superintendent of transportation, the vehicle is bought.

Form No. 1 shows the authorization necessary for the purchase of a specified motor vehicle. This states the use to be made of the machine, whether with or without driver, the account to which the charge is to be made, the classification of the machine and the rate to be charged the department, plus the driver's wages and other expenses.

Form No. 2 is the team authorization, which is similar to Form No. 1, stating the department in which it is to be used, the class of team, whether with or without driver, the number of the account to which charge is made, and the price to be paid weekly.

Form No. 3 is the file record of the automobile, on which is entered the detail, giving the company's number, the manufacturer's number, the registration number, the horsepower, the date purchased, the type of machine, the name of the manufacturer, the cost of the machine, the cost of the equipment in detail, the assignment, the name of the driver and the license number, the amount of depreciation annually, and with space for changes of driver and license number. When the vehicle is sold this is also entered, with the name of the purchaser and the price paid by him.

Form No. 4 is the record of a wagon, showing the company's number, the date purchased, whom it was purchased from, the cost, a brief description, where it is to be located, and the date of location, with space for recording transfers and the dates, the assignments and the date. When sold the name of the purchaser and the price is also entered.

Form No. 5 is the record of a horse, showing the animal's number, the date and from whom purchased, the cost, a description by color, weight, where located, with space for subsequent transfers and the dates, the assignments and the dates. When sold the name of the purchaser and the price is entered.

Form No. 6 is an order for a team, which is an order on the transportation department for a horse and wagon or horses and wagon, which is a departmental requisition for such equipment as may be needed for a given work, stating the time, place and to whom the driver shall report, and the character of the work, which is filled by the head of the department and

approved by the superintendent of transportation. This is a record of special work, and accounts for the time of the driver and the equipment.

Form No. 7 is a teaming ticket, on which all charges are made to the different departments. This indicates the person and the department authorizing the use, the detail of the use, the date of use, the time and the debit, whether the work was teaming (general haulage), freight or express. When this has been approved by the head of the department charged with the work the ticket is sent to the purchasing department and goes through the regular course for audit. The ticket is printed in duplicate, one copy being retained by the department and the other is sent to the transportation superintendent.

Form No. 8 is the regular garage record required by law on which is entered the time of the departure and the time of return of all vehicles, but this form is also used for other record because it indicates all the machines owned by the company by number, and it is a convenient sheet for noting facts that may be desirable.

Form No. 9 is a record of the daily odometer readings of all vehicles stationed outside of the Massachusetts avenue garage of the company, and these are sent to the head of the automobile division for the mileage record.

Form No. 10 is used for recording the daily mileage record of the vehicles and also for recording the daily gasoline consumption, either use being designated by writing one word in the form, for a period of one month. Each sheet will permit the record of 31 vehicles. This is a garage and an office record.

Form No. 11 is used to record the special work of any vehicle for from one to four trips, showing the time of leaving and return, the time in and out of the garage, and the total mileage and the place to where the trip was made, as well as the number of passengers.

Form No. 12 is a record of the service of any vehicle used nights, Sundays or holidays, and this gives the number, the class of car, the date, the department to which the vehicle is assigned for the work, when it was taken out and by whom, when it was returned and by whom, the number of passengers, remarks and the condition of the machine. Each form is signed and is returned to the transportation department. The record is made in duplicate.

Form No. 13 is a requisition blank that is used by all divisions of the department and it may request either purchase or sale, with such explanation as may be desirable. It is signed by the person making the request and in addition indicates the records on which it is subsequently entered, the account and the vehicle for which requisition was made. This is made out in triplicate, and it bears a serial number, by which it may be filed.

Form No. 14 is a receipt for material received from the different departments of the company for transportation by any express company, and is made out in duplicate.

Form No. 15 is a regular card used by the employees of the garage, either drivers, mechanics or laborers, and on it is stamped the time of arrival and leaving for morning or afternoon, with lost or overtime, and on this is also entered the time in hours and minutes, the rate and the total wages due for any given week or less.

Form No. 16 is the regular card that shows the time of the vehicle in and out of the garage, and is stamped in the time clock, and covers a period of one week. This is kept against the number of the machine.

Form No. 17 is used for entering the record of any battery used in the electric machines, each of the batteries being given a number. This indicates the date of installing in a vehicle, the vehicle number, the meter number, the reading, the odometer reading, by whom the reading was taken; the date removed, the meter number and reading, the odometer reading, the mileage and the kilowatt-hours, by whom removed; the date of equalizing, of washing, the capacity if discharged, and the date it was ready for service with remarks. This is signed by the battery man doing the work.

Form No. 18 is used for entering individual battery reports, showing the date, vehicle number, battery number, the readings of the ampere-hour meter and the wattmeter at the starting and finish of charging, the odometer reading, the wattmeter number, the kilowatt-hours of current indicated, the miles run by the vehicle since the previous charging, the ampere-hours of current used in charging, the driver of the machine and the road conditions, together with the usual record of voltage and amperage at different times, and by whom the readings were made and remarks.

Form No. 19 is for charging records of vehicle batteries in groups of 10, covering the voltage and amperage readings for 16 different periods, or half-hour intervals during a normal charge of the batteries. This is a small sheet and is convenient for handling.

Form No. 20 is designed for taking half-hour readings of a battery at any given voltage or amperage, from 76 to 119 volts and from three to 46 amperes, the blank being ruled so that the voltage and amperage may be varied as desired. The record states the number of the battery, the number and size of cells, the make, and the number of the machine in which it is used. This is used generally in testing and forming, it affording a very accurate statement of the charging conditions.

Form No. 21 is the record of the oiling and greasing of each machine and covers a period of one or more months. This is a loose leaf sheet that requires 23 different entries, each showing that a specific part of the mechanism has been given attention, and the odometer reading, which indicates the distance driven between each work. For instance, one date may show but one part of the vehicle was oiled, another any number or all parts, and the odometer readings will indicate whether or not efficient care was given. The man doing each work signs his name and is responsible for the condition of the machine with reference to the work he does. This record is kept for each machine and in binders.

Form No. 22 is for the use of the inspectors of the motor vehicles, and is a complete record on each machine, whether gasoline or electric, and when filled is in duplicate. This provides for both garage and road inspection, and indicates the condition of different groups of mechanism, the accessories, the permanent and temporary equipment, tools, and with reference to cleanliness. These reports are made to the head of the automobile division and from them instructions are given as to care, repair, attention or other requirement. These inspections are made at regular intervals, or at such times as in the judgment of the head of the automobile division as may be expedient, or upon the road.

Form No. 23 is a repair card and it is used for all work on machines other than cleaning, oiling, adjustments and the like. This indicates the number of the vehicle, the date report was made of needed repair and the date the work was completed; the nature of the repairs, and by whom report was made; the time required for the work for seven days and the total time for each day, the number of the account to which charge is made, the rate of labor by the hour, the total cost, and by whom the repairs were made. The reverse of the card shows the vehicle number, the date and the repairs made.

Form No. 24 is a filing card for the convenience of the superintendent of transportation and it is filled with data on overhauling and painting, showing the make of vehicle, the type and the number, the dates of withdrawal and return to service, days out of service, days in repair shop, days in paint shop, average cost of labor an hour, inside labor and outside labor (such as trimming, etc.), new parts and painting, etc., and the total cost. This card will permit four entries.

Form No. 25 is a tire record, begun when a tire is purchased and ended when the tire is no longer serviceable and is disposed of. This requires entries of the size, type, manufacturer, date bought, cost and the number, the dates of putting on and the numbers of the car, the dates of removal, the causes, condition, miles run, estimated mileage remaining, total mileage, cost of repairs and credit value; the total mileage obtained, the total cost, the average cost a mile and explanations or comment. This is the office record.

Form No. 26 is the garage record of a tire and is prepared for loose leaf binding. This gives the tire number, the make, size and style, the number of the vehicles on which it is installed, the date, the odometer reading, the mileage, the dates sent for repairs and the cost of repairs, as well as notes on conditions, etc. This blank provides for four installations on one or more machines. The blank further shows the adjustments, the total mileage run, the total repair cost, the price of the tire, the credits and the actual cost.

Form No. 27 is a heavy tag which is a record of tires installed or removed, and from which the garage and office records are in part made up. This requires entries of the date received, the number of the tire removed, the number of the tire put on, the wheel, the number of the vehicle, the odometer reading, the reason of removal, whether drawn from case or from stock, whether new or repaired, the make, style, manufacturer's number, the date it was placed in the case, whether it is repaired or new, and by whom the change was made.

Form No. 28 is a filing card and is the tire record of the horse and wagon division and it relates to tires used on wagons, showing the wagon number, the wheels used on, the dates put on and the cost, together with remarks.

Form No. 29 is the garage record of the adjustments made with the manufacturers of tires for motor vehicles, and this shows the name of the manufacturer, the date, the number of the tire, the size, the vehicle number, the miles driven, remarks, the cost of replacement and the cost of repairs. This may contain the record of a considerable number, or may refer to a single day or period, but with one manufacturer. This record is made in duplicate.

Form No. 30 is the office record of tire adjustments, and this gives the name of the manufacturer, the date, the company's tire number, the make, size, tread, the disposal made of it, the miles driven, the cost new and value when disposed of, the weight in pounds, the cost by pound, the charges, the credits and the number of the vehicle on which it is used.

Form No. 31 is a record used for the shipments of express or freight and it is a record of the transportation department, but is not a record of the motor vehicle division or its work.

Form No. 32 is the monthly report of the charging of electric vehicles. This requires an entry daily covering the start and finish ampere meter readings, the ampere-hours used, the odometer reading, miles run, ampere-hours a mile, the start and finish watt-hour readings, the kilowatt-hours of charging, the number of the wattmeter, the time put on and taken off charge, the volt and ammeter readings at normal rates at the end of the charging, the battery number, the road conditions, the name of the driver, if the battery were cleaned, if the battery were flushed, the temperature, and the signature of the man making the entry, together with remarks. At the end of the month the record shows the totals for ampere-hours used, miles run, kilowatt-hours of charging, the averages of ampere-hours output, kilowatt-hours input and notes relative to weather conditions.

Form No. 33 is a disbursement sheet, showing the period covered, the number of the vehicle, the name of the account and the account number, the date, the description and the total of material and labor. The record is kept for each machine.

Form No. 34 is a record of automobile vehicles out of commission. This is kept for each machine and it specifies the period covered by the sheet, the dates of the withdrawals from service and the various causes.

Form No. 35 is a record that shows the distribution of the expense of maintenance apportioned to each vehicle from the different accounts. This shows the total expense figured against each machine, the amount from each account being placed in a separate column, from which comparison or deduction may be made.

Form No. 36 is the car ledger for the year and this is kept for each machine. This gives the registration number, the manufacturer's number, the date and from whom purchased, the capacity, power, cost, service, the assignment and the department using it. Under the heading of technical data is kept for each month the miles run, the kilowatt-hours input (if electric), the gallons of gasoline used, the number of hours out of the garage and the number of days used during the month. Under the heading of current running costs is entered the cost of operation, maintenance, tires, running repairs, overhaul and painting, cleaning, care, etc.; alcohol, oil, waste, etc.; electricity or gasoline, sundries and the total. Under the heading of fixed costs are entered the office salaries, office expense, garage wages, garage expense, insurance and rent, garage maintenance, depreciation and the total. Next is entered the driver's wages and the total costs. Against this is entered the rental credits in the form of the current running costs, fixed costs and total, these being a summary of the different items. In addition, is entered the loss or gain, the days the machine was in service and remarks. At the expiration of the year the columns are totalled. Below these are shown the average for each column for the month and for the mile, and with the previous cost brought forward from the preceding year the total to date is obtained. The total is then averaged for the month and for the mile. The second section of the sheet, under the caption of averages per mile, contains the averages of each column above it, this reducing to miles the cost of the vehicle. The third section shows the adjustment figures in a similar manner, and these are totalled as are those of the first section, showing the average per month, average per mile, the previous cost, the total to date, and the average per month and the average per mile of the period of service.

Form No. 37 is the analysis of the transportation clearing account (K 202) for a month. In columns are indicated the account numbers, the name of the account, salaries, labor this month, material this month, total credits, total debits, the balance and comment. Under "Horses and Wagons" is the cost of stable board, horse shoeing, veterinary services, running repairs for wagons and harness, overhauling and painting, cleaning, care, etc.; oil, waste, etc.; hay and grain, sundries, office salaries, office expenses, stable wages, stable expenses, rents, insurance, etc.; stable maintenance, accrued depreciation, drivers' wages, teams hired and charges to departmental accounts. Under "Automobiles" is the cost of battery operation, battery maintenance, tires, running repairs, overhauling and painting, cleaning, care, etc.; electricity or gasoline, sundries, office salaries, office expenses, garage wages, garage expenses, rents, insurance, etc.; garage maintenance, accrued depreciation, chauffeurs' wages, automobiles hired and charges to departmental accounts. Both of these sections are totalled. Then is specified the reserve for depreciation for horses and wagons and for automobiles, and the total depreciation, and then the total of the transportation department clearing account.

The following explanation will serve to make clear the accounts of the car ledger. "Battery Operation" covers all items of expense in the daily operation of the machines and small renewals, but "Battery Maintenance" includes only the complete renewals, while "Overhauling and Painting" covers the annual overhauling and all painting, and such other repairs as are carried into the running repair account. The item of "Office Salaries and Office Expenses" covers the expense of the clerical division and the superintendent's office.

Depreciation is on the basis of three years for gasoline cars and machines and six years for all electric vehicles. Referring to the car ledger, the upper portion of the sheets shows the actual costs, but the lower portion the "adjustment figures." The adjustment figures have a specified purpose. In making up the figures for the year or the period the machine has been in use the account may be misleading from the fact that the three items of "tires", "battery maintenance" and "overhauling and painting," which make a comparatively large part of the total expense, do not appear often. Possibly with a new machine these would not appear in the first year, and to show more accurately what the machine is costing the adjustment figures are computed and entered. The depreciation is figured on the entire cost of the vehicle, including tires and batteries, but less the estimated salvage. In the adjustment figures the cost of tires and batteries is omitted. These figures have been worked out completely each month, but when sufficient data have been accumulated it is probable that this will be done but once a year, when the final cost figures are computed.

All the original charges recorded in the books of the transportation department are sent to the accounting department, where the total figures for the various accounts are kept, and at the end of each month a report is submitted to the transportation department, showing the total cost of operation. It will be noted that the statistics show the cost of operating any given vehicle by the mile, day, week, month or year. This information is also kept in a pocket data book, showing the comparisons of the operating cost by month and by year, and these costs are reduced to cost a mile, so that the superintendent of transportation may at any time determine the efficiency of the department.

Over 100 White motor trucks, made by the White Company, Cleveland, O., are used to make deliveries to Pittsburg, Penn., shoppers. Three of the prominent department stores of that city have added White machines to their equipment. The Rosenbaum Company, which has operated seven Whites, placed its order for six more; Boggs & Buhl, Inc., which has operated 10, brought its total to 16, and Solomon & Co., purchased two.

The Commerce Motor Car Company, Detroit, Mich., maker of Commerce delivery wagons, has plans for largely increasing its production the coming year. The company has now more than 300 machines in operation in different sections of the United States, and with the experience of three years, having well established the utility and practicality of the wagons, the purpose is to manufacture them in larger numbers through a well organized and efficient selling force.

BOSTON EDISON COMPANY'S TRANSPORTATION DEPARTMENT OPERATING RECORD FORMS.

The insert facing this page shows the 37 different record forms used in operating the Transportation Department of the Edison Electric Illuminating Department of Boston, each of which is designated by a number shown within a circle, and on this page the use of each form, the color of paper, ruling and printing, as well as the dimensions, are stated. Reference to the insert will show any desired form and its general proportions and makeup, while on the preceding pages a brief description of each may be found. The arrangement of the forms on the insert is not in the order of use, but to convenience reproduction, and the numbers will be found to be so applied as to group the several records of each department. In several instances forms requiring similar entries may be noted, but one of these is for use in the garage office and the other for the office of the superintendent of the transportation department.

This series of forms has been developed from an experience covering years, and the value of each record has been established beyond question. The company has an extremely comprehensive system, and the possibilities of economy are such as to justify what may appear to be without reflection a complex or unnecessarily careful administration.

No. 1, Automobile Authorization, typed in purple on white filing card, five by eight inches, unruled.

No. 2, Team Authorization, typed in purple on white filing card, five by eight inches, unruled.

No. 3, Record of Car, printed in black on white filing card, head rule of red and body ruled with blue, five by eight inches; reverse of card similarly ruled.

No. 4, Record of Wagon, printed in black on white filing card, ruled both sides with blue, five by eight inches.

No. 5, Record of Horse, printed in black on light yellow filing card, ruled both sides with blue, five by eight inches.

No. 6, Order for Team, printed in black on white paper, 5.25 by 8.25 inches.

No. 7, Teaming Ticket, printed in duplicate on white paper and light white card, and numbered serially, five by eight inches; padded.

No. 8, Checking Sheet, the record of vehicles leaving and returning to the garage required by law, printed in black on white paper, ruled with blue, with red vertical lines between the rules enclosing the vehicle numbers, 15 inches length by 8.5 inches width.

No. 9, Daily Odometer Record, for vehicles stationed in suburban districts, printed in black on white paper, 5.5 inches length by 3.75 inches width.

No. 10, Daily Mileage and Gasoline Record, printed in black on heavy white paper, with head, foot and left end rule of blue, horizontal ruling blue and vertical ruling red, 10.25 inches length and 20 inches width.

No. 11, Special Report on Car, printed in black on white filing card, with head rules in red, horizontal ruling in blue and vertical ruling in black, three inches length and five inches width.

No. 12, Report on Car Used Nights, Sundays or Holidays, printed in duplicate on white paper and light card, five inches length and eight inches width.

No. 13, Request for Material, used by all departments, printed in black in triplicate on two sheets of white paper and a light card, with head and foot ruling in red and line ruling in blue, five inches length and eight inches width.

No. 14, Receipt for Material, for shipments made by express, printed in black in duplicate, the original on white paper and the copy on yellow, numbered serially and padded, four inches length and seven inches width.

No. 15, Driver's Time Card, used in time clock, printed in black on obverse and red on reverse of manila card, 5.5 inches length and 3.5 inches width.

No. 16, Car Time Card, used in time clock, printed in black on obverse and red on reverse of manila card, 5.5 inches length and 3.5 inches width.

No. 17, Battery Record Tag, showing installation or removal and condition of battery printed in black on manila card, eight inches length and four inches width.

No. 18, Battery Charging Report, printed in black on white, 8.5 inches length and five inches width.

No. 19, Charging Record of Batteries, to show the conditions at half-hour intervals by volt and ampere meter readings, printed in black on yellow paper, padded, 8.5 inches length and 10.5 inches width.

No. 20, Charging Record of Battery, to show conditions at any given voltage or amperage, at half-hour intervals, printed in black on yellow, with cross and vertical ruling in blue, 15 inches length and nine inches width.

No. 21, Car Oiling Record, printed in black on white paper, head and vertical ruling of red and cross ruling of blue, perforated for loose leaf binding, 11 inches length and 8.5 inches width.

No. 22, Automobile Inspector's Report, printed in black on white paper, 14 inches length and 5.75 inches width.

No. 23, Automobile Repair Card, for use in the garage, printed in black on both sides of a manila card, 5.5 inches length and 3.5 inches width.

No. 24, Data on Overhaul and Painting, for office reference, printed in black on white card with head and foot ruling of red and cross ruling of blue, three inches length and five inches width.

No. 25, Office Record of Tires, printed in black on white filing card, with ruling of blue, five inches length and eight inches width.

No. 26, Garage Record of Tire, printed in black on white paper, perforated for loose leaf binding, 8.5 inches length and width.

No. 27, Record of Tire Installation and Removal, printed in black on manila card, 5.5 inches length and 2.75 inches width.

No. 28, Wagon Tire Record, printed in black on white filing card, with head and foot ruling of red, cross ruling of blue, and vertical ruling of black, three inches length and five inches width.

No. 29, Garage Tire Adjustment Record, printed in black in duplicate on white and yellow paper, with vertical ruling of red and cross ruling of blue, padded, 10.5 inches length and eight inches width.

No. 30, Office Tire Adjustment Record, printed in black on white paper, with ruling of red and blue, 11 inches length and 8.5 inches width.

No. 31, Freight and Express Shipment Record, printed on either side in black on white, with head, foot and vertical ruling of red and cross ruling of blue, cut for loose leaf binding, 11 inches length and 15.25 inches width.

No. 32, Monthly Battery Charging Report, printed in black on white, vertical ruling of red and cross ruling of blue, perforated for loose leaf binding, 18.5 inches length and 14 inches width.

No. 33, Monthly Disbursement Sheet, printed on either side in black on white, ruling of red and blue and of both colors, cut for loose leaf binding, 14 inches length and 13 inches width.

No. 34, Record of Automobiles Out of Commission, printed on either side in black on white paper, vertical ruling of red and cross ruling of blue, cut for loose leaf binding, 14 inches length and 13 inches width.

No. 35, Monthly Accounts Pro Rated Sheet, printed on either side in black on white paper, with vertical ruling of red and cross ruling of blue, cut for loose leaf binding, [illegible] inches length and 13 inches width.

No. 36, Car Ledger Leaf, printed in black on white paper, with ruling of red and blue, perforated for loose leaf binding, 13 inches length and 22.5 inches width.

No. 37, Analysis of Transportation Department Clearing Account Sheet, printed in black on pink paper, with ruling of blue and red, perforated for loose leaf binding, 10 inches length and 17 inches width.

ANALYSIS OF VEHICLE SERVICE.

Scientific Study of Well Equipped and Assumedly Economical Equipment Shows That the Actual Working Hours are Surprisingly Small and Time Is Very Valuable.

THERE is no more important factor in economical transportation than the productive time of the vehicles in service. The best equipment and the most

The Servis Recorder Case as It Is Installed on a Vehicle for Recording Mileage and Speed.

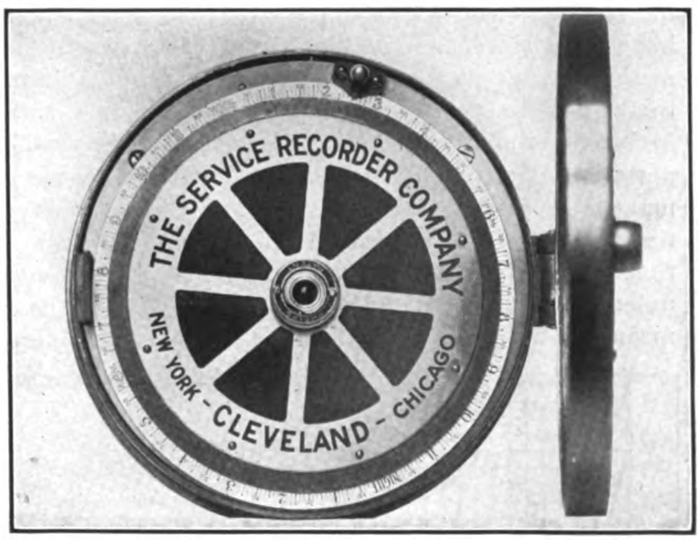
approved facilities are valueless if not profitably used, and when the possibilities for loss are considered the study of actual working time becomes the more significant. By this is meant that a record is without value if it is not used, and if it used then it should be so utilized that it will produce economy to the greatest practical extent.

Probably 75 per cent. of the vehicles used for haulage are in service during what may be regarded as the business hours of the day, from 7 in the morning until 6 at night. The other 25 per cent. are utilized during the remaining 24 hours of the day. Wherever the business interests are large the traffic in the highways is correspondingly heavy and delays from differing causes are material. In practical transportation not half the actual mileage is doing profitable work. Assuming that each vehicle were fully loaded for each trip made, and returned empty, there would still be such work as going from the garage to the place of loading and returning, to say nothing of incidental trips, which would probably reduce the actual work to 45 per cent. of the mileage. There is every reason to believe that this figure is conservative.

Assuming that the vehicle were in continuous service during 10 hours each day, then 4.5 hours would be in productive haulage, and the remainder of the time would be unproductive. The possibility for economy would be to increase the percentage of productiveness, which could not, without carrying loads when returning, be increased to more than 50 per cent., or five hours. This might be accomplished where the garage was in combination with the place of business, warehouse, factory or shop, but this condition is not always possible to develop. In proportion to the decrease of actual haulage time is the loss in productiveness, but it will be seen that the loss of an hour of a 10-hour working day is not a shrinkage of 10 per cent., so it is a decrease of 12.5 per cent of the productive time of the vehicle.

The usefulness of any machine depends upon its operation. This is true of the motor wagon or truck. If there be delays in loading, in driving, in unloading, from accident or any other cause, then this is a direct loss that cannot be made up, and it is well enough known that overloading, or fast driving with or without load, will not compensate for losses through delay, because of the destructive influences upon the vehicle. Common sense dictates that these cannot be permitted. Economy demands that the machines be operated with care and kept moving as much of the time as is practical. Whatever time is taken from the service time of the wagon or truck for loading, for delivering, for traffic delays, for adjustments or repairs upon the road is the loss of the owner, and the value of this time is seldom realized or understood.

The determination of the actual work performed depends practically upon the form of record made. Primarily it is not possible to have a definite load unit that can be generally applied, and the loads will vary widely. There are instances where the loads may be standardized, but these are not often met with. If one



The Case of the Servis Recorder Opened, Showing the Circular Chart on Which the Data Are Automatically Noted.

were to keep precise data of the loads this would necessitate more labor, and this is to be avoided when possible. In many cases loads will differ as to weight and

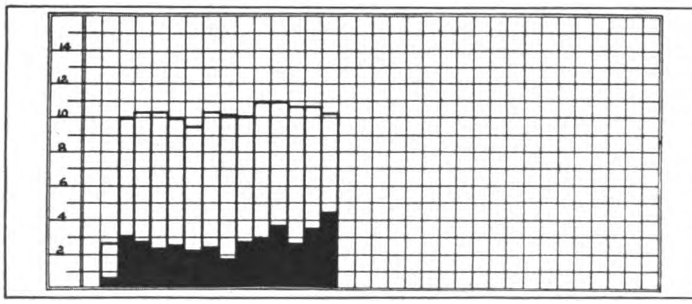


Fig. A—Graphic Chart Showing Two Weeks' Test of 10 Trucks in Heavy Haulage Service.

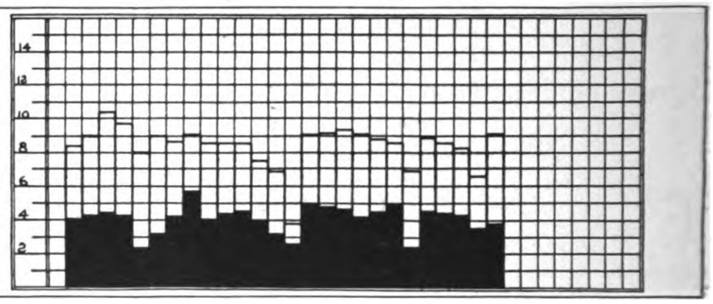

Fig. B—Record of Cleveland-Akron Bag Company's Equipment Fitted with Recording Instruments.

bulk and to average them does not afford the result sought. When freight is weighed and the mileage is known one basis accepted is tonnage and ton-miles, but where packages and goods of variable bulk and weight are carried, sometimes the cost of each is averaged. But where productive time is to be ascertained the assumption must be that the loads are normal—the capacity of the vehicle. Otherwise a smaller machine would be more economical. Surprising as it may appear, the general inclination is to overload motor wagons and trucks, which is destructive of mechanism and tires, and to disregard the time of productiveness. This is a more general fault than is almost believable, and instead of the economy that might be possible there is a loss that is seldom realized.

There are those who have accurate record with reference to administration, operation, care, maintenance and expense from every angle, who do not give the attention to the economy of productiveness that is desirable or necessary. The fact that this is neglected is because there is indifference as to methods or a continuance of work under conditions that existed with horse equipment. There can be no doubt that no manufacturer or business man generally would purchase improved machinery and continue manufacturing as before. He desires to realize the fullest benefits of his increased productiveness, and it was this prospect that impelled the change. This being so he adapts his methods to whatever the requirements may be. But this is not done with motor transportation equipment.

Those who have given careful attention to transportation efficiency understand that the working time may be of practically any length and the productive time, which is the real factor, but a very small part of this. There must necessarily be time for loading and unloading, but all stops or delays aside from these mean a sacrifice of useful work. How this can be best economized is a problem that can only be ascertained by careful study, and by comparisons of the working time and the actual working time. Figures do not always adequately represent these, because few can measure accurately by a measure they cannot readily picture, but by charting these by days it is practical to reduce the factors to a state where they can be clearly understood.

Of course it is necessary to obtain specific information, which cannot be done without a dependable instrument that will record the facts essential to such analysis, but when this has been secured the reduction can be made in whatever manner will best serve. Some extremely interesting facts have been developed by the Service Recorder Company, Cleveland, O., in studies of delivery work of different companies that use the instruments made by this concern, and these have been presented in chart form that the statements made can be the better understood. Without question the operation of the motor wagon or truck is not within the control of the manufacturer of the machine, though it is entirely practical for his representatives to observe the work and to make recommendation for service, but a very large proportion of owners, while they will agree that the principal object to be accomplished with motor equipment is to keep it moving, will not admit that their own service is in any way inefficient.

The man who makes his own comparisons from reports submitted does not always grasp the conditions as they really are, and some can only comprehend fully where losses are experienced when attention is directed specifically to some glaring fact. Perhaps this statement is best emphasized by the quotation of this paragraph from a letter received by the Service Recorder Company:

> We are glad to tell you for your information that we are now operating one five-ton ...., two 3.5-ton .... and one two-ton .... While these trucks are giving us

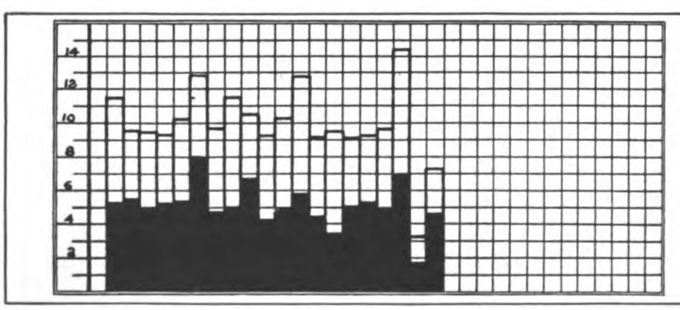

Fig. C—Chart of Halle Bros. Company, Cleveland, O., Showing Result of Superior Loading Facilities.

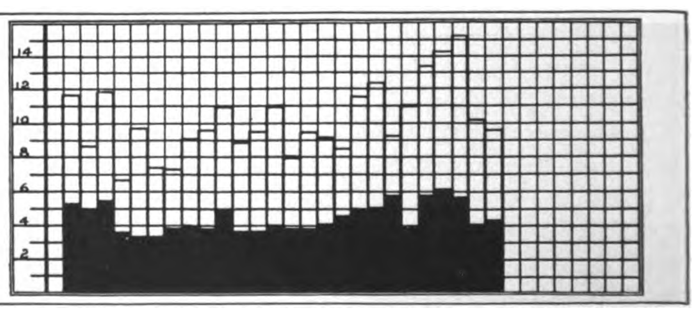

Fig. D—Work of May Company's Equipment, Cleveland, O., Reduced Service Resulting from Conditions of Doing Business.

very good service, we find the expense of the upkeep a great deal more than horses. We are perfectly willing to concede that a gasoline truck does more work than a team of horses, but we cannot yet figure out after our depreciation, insurance and wage charge are accounted for, whether we are going to come out as cheap at the end of the year as with horses. We can get all the teams we want for $6 a day and the trucks do not do all the work that two teams would and we cannot operate a truck for $12 a day. It may be due to the fact of our driver, etc., and that is what we are willing to spend a little money to determine.

The statement was made that the actual working time, not productive operation, was in this case not four hours a day, and a test for a week showed an average of two hours and 40 minutes, which was a sufficient explanation of the condition that had been stated by the owner. It is quite needless to state that this analysis resulted in a substantial improvement and decidedly greater efficiency. Assuming that the loading facilities are reasonably satisfactory and the delivery conditions such as are customarily met with, the statement is made that a machine should be moving 66 per cent. of the working hours, this giving the remaining 34 per cent. to loading, unloading and the delays that may be experienced from causes beyond the control of the driver or the owner.

In connection with this some decidedly interesting charts have been prepared by the Service Recorder work in the same city, so that the comparison may be regarded as being as fair as could be made.

Fig. C chart is plotted from the records of Halle Bros. Company, a well known department store of Cleveland, O., and its usefulness can best be understood by comparison with Fig. D, which is similarly plotted from the records of the May Company, which also conducts a department store in that city. The difference in service time may be credited to superior loading facilities and to a different class of dwellings and to the fact the packages are lighter and smaller as a rule. In Fig. D it may be noted that there is considerable variance in the actual working time, and the delivery made shows that the greatest volume of business is at the first and last of each month.

Fig. E shows the chart compiled from a month's work by the delivery equipment of a firm that is using seven trucks to do what could be done with five machines, and the first three weeks represent an average of 70.6 per cent. of the service time the machines were not working, and the highest daily tonnage was 69,000 pounds. The fourth week the percentage of working time was increased to 34 per cent., with an increase of the daily tonnage to an average of 89,000 pounds.

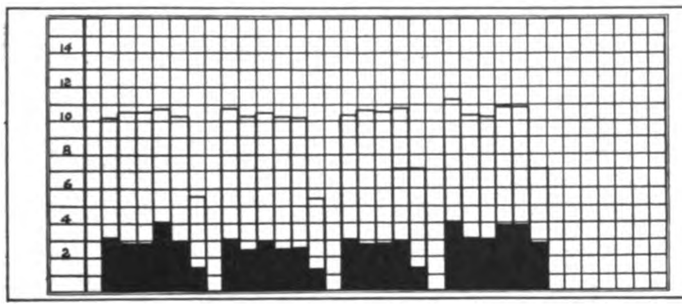

Fig. E—Showing 70 Per Cent. Idle Time for Three Weeks and Reduction to 66 Per Cent. by Improved Supervision.

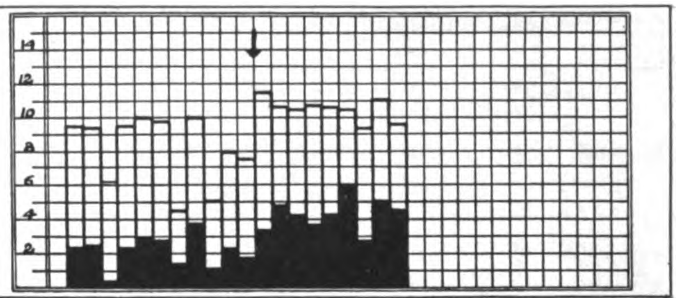

Fig. G—Chart Showing Work for Two Without Recorder Data—Arrow Indicates Improvement After Information Was Used.

Company which show the proportion of actual working time, not productive time, to the daily service of different haulage equipment. That shown at Fig. A represents a two weeks' test of the service of a concern that used 10 heavy duty gasoline trucks for inter-factory and delivery haulage. The slight improvement indicated in the last four days was caused by casual supervision of the shipping department. When this test was made the company was considering the purchase of several more machines, and the record showed that better administration and not more machines was needed. In reading these charts the vertical columns indicate days and the transverse columns indicate the hours of the day up to 16, and the figures shown at the left side indicate the hours in multiples of two.

It will be noted there is a considerable difference when comparison is made of Fig. A and Fig. B, the latter being a record of the service of the Cleveland-Akron Bag Company, which has its equipment fitted with recorders. Fig. B shows that the service time is less, but the actual working time, and consequently the productive time, is greater. The trucks are similar in size and make and are engaged in a similar class of

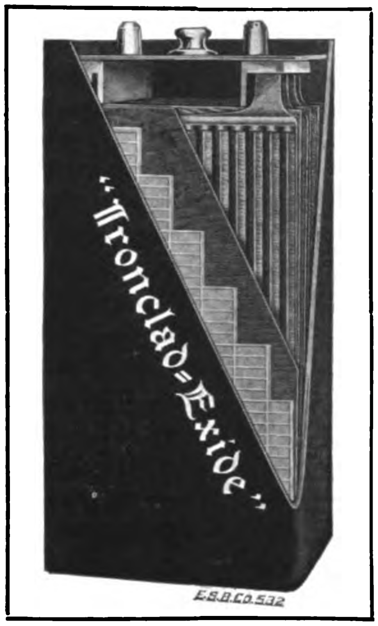
Fig. G is the charts of two weeks' work for a firm that was made with a recorder equipment, and the arrow indicates the day when the drivers and the shipping clerk were both notified of the need for improvement. When the full equipment was installed the percentage of working time fell below the results shown by the last half of the charted record, as there was not sufficient work to keep all of the machines busy, and the shipping clerk admitted that while the recorder was on but one truck the vehicle and the crew were worked to the extreme to make a showing.

The value of such records is demonstrated from the charts, for they afford a means of accurately measuring the proportions of the service time the vehicles are actually working, and by record of the loads carried the real productiveness of any vehicle or number of vehicles can be very accurately determined. Carrying the analysis further, it is practical for an advertising manager or merchandising manager to study the number and character of stops made in any given section of a city, and by study of that section to determine what best appeals to the residents, and whether a given section or a specific class of residents yields profitable business.

THE SIMPLICITY OF THE LEAD BATTERY.

By C. H. Bristol.

WITH the enormous increase in the use of electric trucks should naturally come a corresponding interest in storage batteries. "Electrics" in their proper fields of service have been proven to furnish the most efficient and economical form of transportation for city and suburban use. For various reasons, however, truck owners and prospects have not always given sufficient time and attention to properly investigate batteries, and to learn of the differences in the various types and of the simplicity in the care and operation of the lead battery, which is so universally used. The battery is a most important part of a car, since it furnishes the power for propulsion, and since the efficient and economical operation of the car depends largely on the battery.



Sectional View of "Ironclad-Exide" Cell.

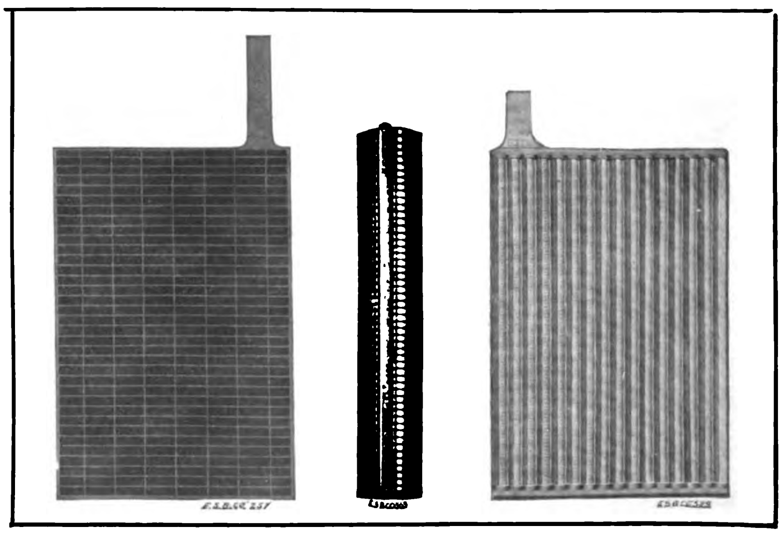
This reluctance on the part of merchants and manufacturers to give the battery proper consideration has been due, as stated, to a number of causes. First, perhaps, it has been due to the numerous stages of development through which the lead battery has passed to its present state of perfection; second, to the technical and uncommon terms usually used in describing it, and third, knowing that the battery was both a chemical and electrical proposition, they had inferred it was naturally complicated and without investigation have simply evinced no further interest.

It is true in the case of the lead battery, as in many other pieces of apparatus or articles which have gone through numerous stages of development and refinement, that the present lead battery is an entirely different proposition from the earlier batteries that were developed and in many cases marketed, and the failures of earlier types have been an obstacle which the present lead battery manufacturers had considerable difficulty in overcoming. The mere fact an electric vehicle is operated by a storage battery has been enough to frighten away some truck users.

However, in contrast, it has been interesting and instructive to note that many large concerns who have tested and used "electrics" have regularly added them for delivery or haulage service and these same concerns are now among the largest users of this type of vehicle. In all fields, including both light delivery and heavy haulage, "electrics" are being adopted in large numbers. Such a showing is perhaps the best evidence to the storage battery agnostic that the present lead battery is a practical and dependable source of power for propelling a vehicle.

It has, of course, taken years of work and experience to develop the present type of battery. The first type of storage battery was developed in 1860 by Plante, from whom one type received its name. The forming of the active material on this plate proved to be such a tedious and expensive process that it was only used for few purposes. In 1880 came a wonderful advance in the art when Faure brought out a plate in which the active material was placed in a lead blank in the form of paste. This improvement was looked upon then as the final answer in storage batteries, with the result that large quantities of these batteries were at once manufactured. This type of battery, however, also proved to be unsuited and it was its failure which gave the lead battery a set-back that took years to overcome.

In 1895, when electric vehicles first appeared, battery manufacturers turned their attention to the development of an electric vehicle battery. The well known "Exide" battery was then brought out. This battery has been improved from year to year, and having stood the test of time, is now used in thousands of "electrics". It was the successful result of an attempt to make a vehicle battery that would give sufficient capacity and at the same time long life—this accomplishment having been previously tried with all attempts resulting in failures. The early success of the "Exide" battery was due no doubt to the years of ex-



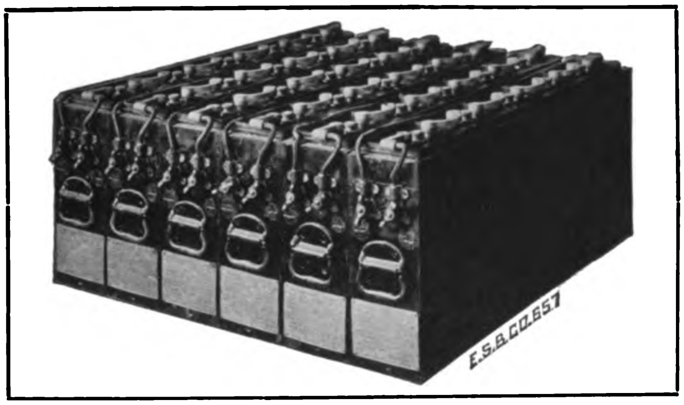
Electric Storage Battery Company's Construction: Exide Positive Plate; Horizontally Slotted Hard Rubber Tube of "Ironclad-Exide" Positive Plate; "Ironclad-Exide" Positive Plate.

perience that the manufacturer had in other fields of storage battery use.

For years this type of battery has made remarkable showings in electric vehicle service and the growth in the use of "electrics" was in no small measure due to its success. Modifications of this standard design, which has been used in a large percentage of all "electrics" manufactured, followed. The demand for greater mileage among some users was met in the "Hycap-Exide" battery and later when even longer distances must be covered by one charge of a battery, the "Thin-Exide" battery was developed.

During these years in which the pasted plate type of battery was showing such good results, there had been one feature of its design which showed promises of improvement. Vehicle users found that it was sometimes an annoyance to take a vehicle out of service for cleaning the battery, this being necessary, due to the fact that part of the plate material had been shed and had collected in the bottoms of the battery jars, where, if allowed to remain, it piled up, short circuited the plates and thus seriously affected the capacity.

This, the last and only objection that could possibly be raised against the lead battery, was completely solved in the "Ironclad-Exide" battery. This improved type of battery, instead of using for the positive plate a metal grid into which the active material is pasted, uses a series of hard rubber tubes containing the active material, which are horizontally slotted, allowing the free circulation of electrolyte. This new and latest type of battery has overcome the annoyance and expense previously experienced from taking a vehicle out of service for battery cleaning. The reliable day-in and day-out service from an electric truck, which is such a desirable feature, is now assured.



Thirty-Cell Type 13 MV "Hycap-Exide" Battery in Six Trays.

An interesting feature in connection with the development of the lead battery has been that at the same time the battery was being developed to give more capacity and longer life, it has also in turn been simplified so that it could be more easily operated and cared for. Referring again to the "Exide" battery, which has been chosen for illustration on account of its wide use and familiarity among vehicle users, it is found that the instruction book furnished to a vehicle user is a small envelope size pamphlet of but six pages. This in itself should instill confidence in the mind of an electric truck owner or prospect and at least prompt him in finding out what these few pages contain.

There are but few rules to be followed in connection with the use of a lead battery such as one of the four "Exide" batteries. Any man of ordinary intelligence who will give a battery a reasonable amount of attention can procure perfectly satisfactory service from it. There are, of course, exceptional occasions when conditions arise with which a man is not familiar, but at such times he can readily obtain advice or information of any kind by communicating with one of the sales offices or depots of the battery manufacturer, which are conveniently located in various cities about the country.

The operation and care of a lead battery is in no way complicated and with ordinary care will give excellent service. Good evidence of the simplicity in the care and operation of a lead battery is shown by the thousands of owners of electric pleasure cars—many of them being women—who take care of their own batteries and who had no knowledge of storage batteries until they purchased an electric car.

"FENDERIZING" MOTOR TRUCKS.

Chicago Owners of All Service Vehicles Have 90 Days to Comply with Ordinance.

Unless some of the city solons repent and suspend or extend the provisions of an ordinance recently enacted by the city council of Chicago, it will be necessary for the owners of all vehicles used for business purposes, aside from carrying passengers, within 90 days, to provide them with "a fender, as in the case of street cars operated and used within said city", such as may be approved by the board of inspectors of public vehicles.

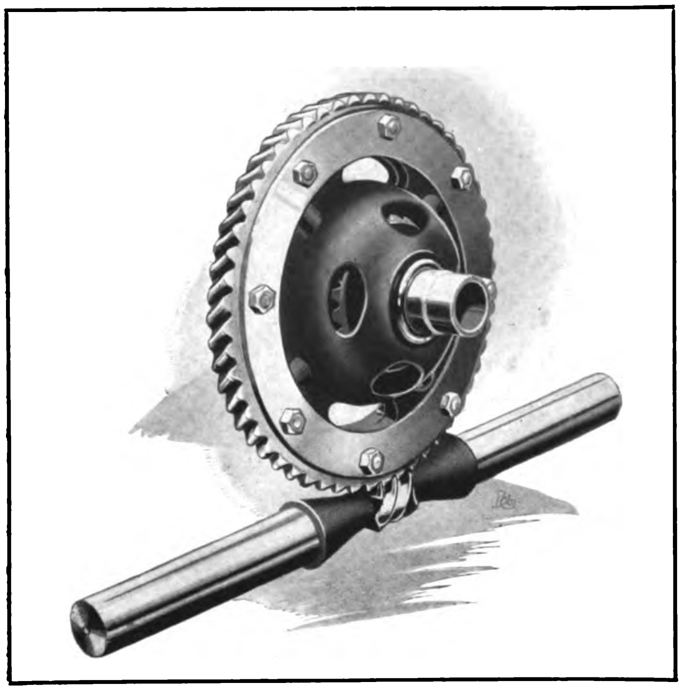
So far as known the only motor vehicle ever constructed that was equipped with a fender was that built for John Shepard, Jr., of Providence, in 1896, and this was for the purpose of exploiting the device as applicable to street cars rather than with any idea that it would be useful with motor carts and wagons. In this case the machine was more of express wagon construction than what is now regarded as conventional truck design, and the fender was permanently located.

To afford satisfactory protection a fender must be ahead of the wheels and be so low that it will lift an object, and to have the strength and permanency the construction must be well designed and be so adapted that it will not reduce the utility or efficiency of the machine. Just how the Chicago men are going to meet the problem is unknown, but there is no doubt that the ordinance, if it is not materially changed, will be a hardship for the owners of vehicles and will militate against the further use of power wagons and trucks in that city.

THE WARNER-LANCHESTER WORM DRIVE.

By Paul Davies.

DESPITE the great progress which has been made during recent years in every branch of engineering knowledge, there still remains a certain prejudice against the use of worm gearing. This is due to a variety of reasons. In the first place, there has always been a general impression that worm gears were inefficient compared with bevels or with chain drive, and even when this view was proved to be unfounded, those manufacturers who took up the supply of worm gears failed to secure the necessary accuracy of workmanship and high quality of materials which are essential for the securing of satisfactory results.



The Warner-Lanchester Worm Shaft, Gear and Differential.

In consequence of these facts, many car manufacturers who have experimented with worm gears have not obtained good results and have therefore reverted to the use of bevels, acting under the belief that satisfactory worm gears were unobtainable.

This is quite an erroneous idea, and we would impress upon the reader two main facts: That worm gearing of the type constructed by us is as efficient as the best of bevel gears, and that, so far as durability and freedom from trouble are concerned, these worm gears are absolutely satisfactory in every way and, indeed, superior to bevels, in that they run noiselessly without the need of adjustment.

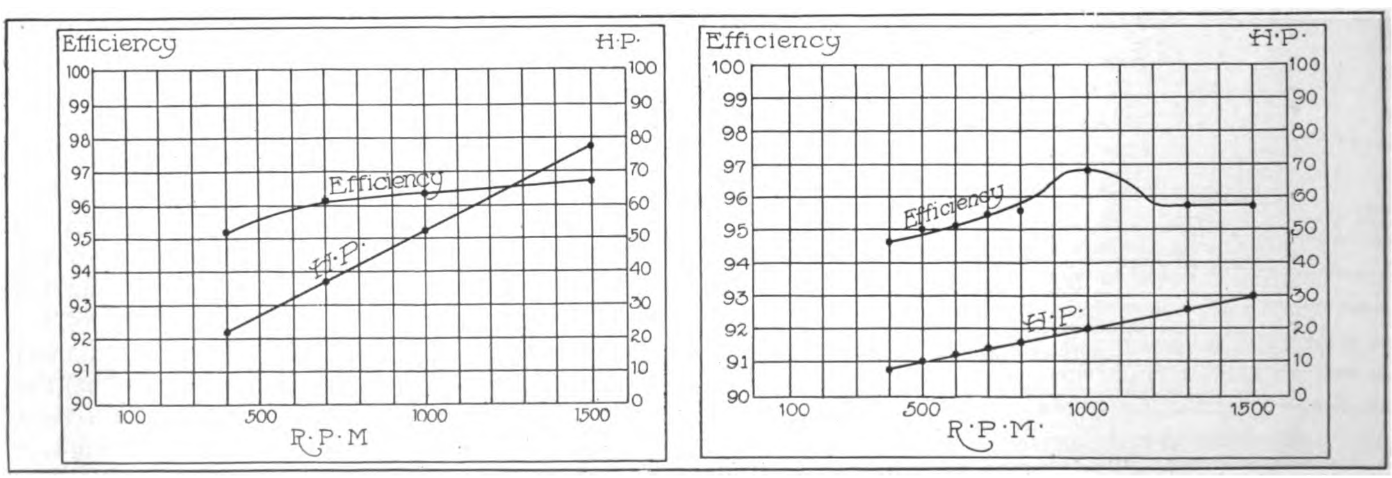
The advantage which worm gears offer in comparison with bevels are widely known, and it is hardly necessary to do more than recapitulate the chief points. What we have to emphasize most strongly is that on the one feature which has previously been regarded as debatable—the efficiency of transmission—there is no longer any room for doubt. As far as efficiency is concerned our worm gears are quite equal to the best bevels manufactured.

The Warner-Lanchester worm gear has much in common with the Hindley worm. That is to say, the worm and wheel are of a form mutually adapted to each other. The teeth are fully entered during the whole of their engagement and are entirely free from the tooth form difficulties of the ordinary parallel type of gear.

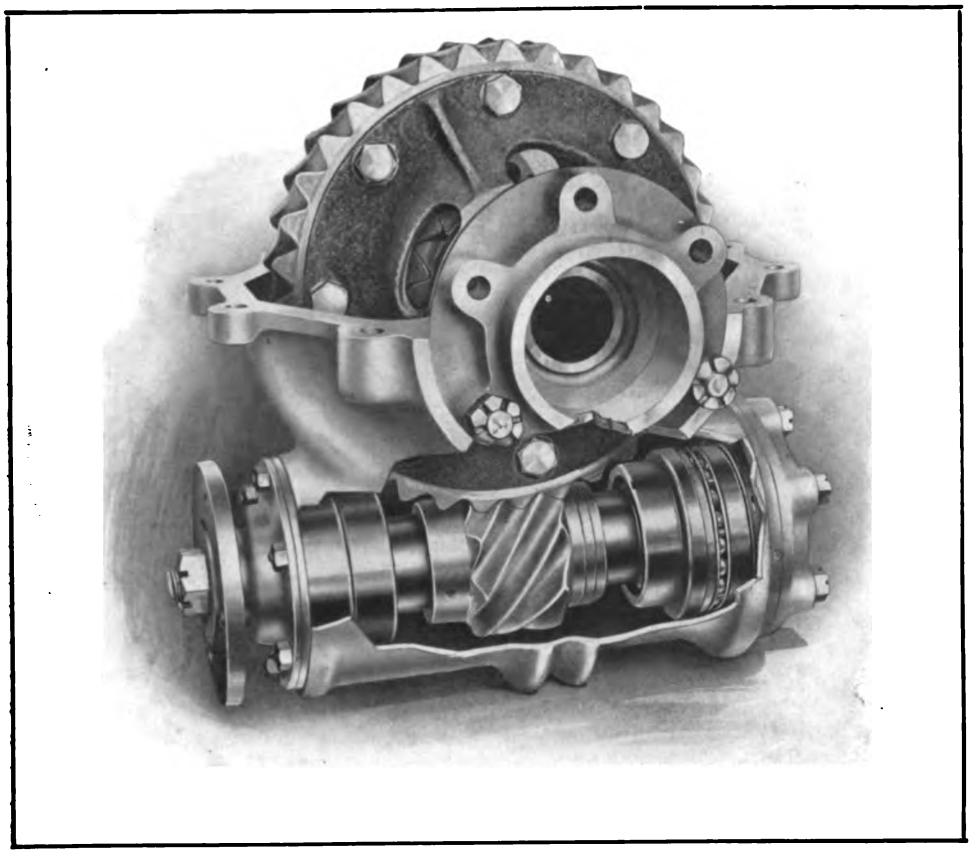
Silence and Strength.

Worm gearing provides a smooth and uniform means of power transmission. This contrasts favorably with the intermittent action which obtains in the case of bevel gears, and which is the cause of the humming noise characteristic of the bevel drive. But apart from the big difference in the actual nature of the impulse, it is important to note that in worm gears the load is distributed over several teeth—in the Warner-Lanchester worms there are always three teeth sharing the load at once.

In bevel gears, however, there is only one tooth actually transmitting power at any particular instant; the other teeth just coming into or leaving contact hardly bear any appreciable share of the load. Hence it will be realized that worm gears are much stronger



Efficiency of Worm Gearing: At Left, 9-34 B. L. H.; at Right, 8-35 B. L. H.—Plotted from Tests Made by the National Physical Laboratory of England.



Phantom View of the Warner-Lanchester Worm Shaft and Gear.

in every way than bevels and that they can be subjected to a considerable overload without risk of failure.

Another important fact is that the wear which takes place on the worm teeth in course of time does not affect the efficiency or silence of running of the gears in any way. On the other hand, worn bevels are invariably noisy and are, in addition, much less efficient than newly-cut gears.

Bevel gears have but a limited range as far as gear ratio is concerned, but with worm gears there is no difficulty in obtaining as big a reduction as is ever likely to be required. This is an important fact in the case of commercial vehicle work; here, the use of a single pair of worm gears replaces the double set of bevel and spur gears necessary when a big reduction is required.

Even more important is the thoroughness of the lubrication obtained with the hollow worm gears. By reason of the fact that the area of pressure moves right across the face of the tooth, there is a constant passage of oil to the regions of highest pressure. The value of this fact cannot be over-estimated; it at once places the Warner-Lanchester worm gears on a level far above the ordinary type of gearing.

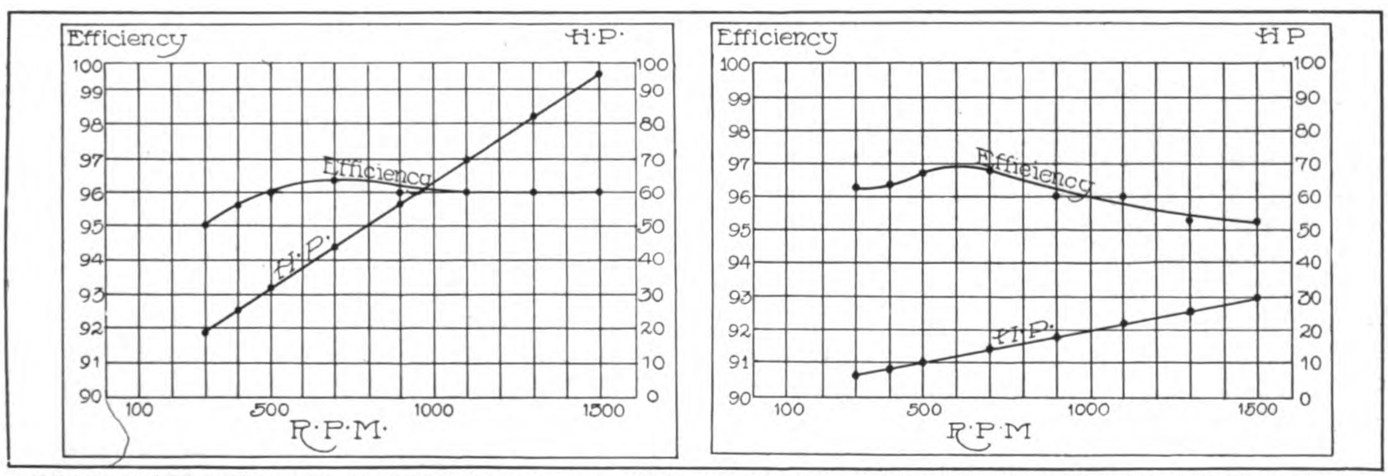
Efficiency.

Recent investigations have shown that the efficiency of the Warner-Lanchester worm gear under ordinary conditions of usage (that is to say, at worm speeds ranging from 500 revolutions upwards) is over 95 per cent., and efficiencies of 97 per cent. and above have been recorded.

The measurement of high efficiencies such as these presents difficulties of a serious kind, and the usual method of measuring power input and output separately cannot be relied upon, the errors of the experiment being far too serious.

The new Daimler testing machine (the invention of F. W. Lanchester, patent applied for,) has been designed to give a direct measurement of efficiency and successfully performs this with an error of probably less than one-tenth of one per cent. The new testing machine insures certain special refinements both as to finish and lubricant. The advantages of these separate improvements could not have been detected by previous methods, but their accumulated effect is of most marked value.

The actual results of careful tests are shown in the following figures, which call for no explanation. It will be observed that the efficiency is quite high, even



Efficiency of Worm Gearing: At Left, 10-31 B. L. H.; at Right, 8-33 B. L. H.—Plotted from Tests Made by the New Lanchester Machine at the Daimler Company's Works.

at low speeds—this is the point which we desire to emphasize.

Overload Capacity.

One of the most important features of the Warner-Lanchester worm gears is their ability to withstand excessive loads without damage. This overload capacity is a very great advantage in view of the heavy driving and braking stresses which can be imposed on the transmission gearing by a careless driver. With bevel gears there is always the danger of stripped teeth, but such an occurrence is an impossibility if worm gearing is employed.

As with every other form of gearing, proper lubrication is an essential condition for obtaining satisfactory results with worm gears. Under normal conditions of running, our worm gears will outlast bevels of similar service, with this important difference, that the worm gears will always run as silently as they did at first, whereas with bevels a certain amount of adjustment is necessary when wear has taken place.

Position of Worm.

The standard position of the worm is below the axle; lengthy experience has proved that this is the best method of ensuring adequate and constant lubrication—especially at low speeds. The Warner Gear Company recommends the worm beneath the worm wheel, and this practise has been adopted by almost all car manufacturers who employ the silent drive. However, when special conditions, such as the necessity for maximum ground clearance, render it advisable to place the worm on top, this may be done, provided that precautions are taken to ensure a copious supply of oil at all times.

DISCUSS PARCEL DELIVERY.

Motor Truck Club of New York Listens to Department Store Shipping Heads.

The September meeting of the Motor Truck Club of New York was given over to the consideration of parcel delivery by motor truck, and the subject was discussed by club members and some of the heads of the shipping departments of New York department stores. The club membership is composed of men active in the industry and trade, as well as those connected with industrial and commercial enterprises, and the discussions are intended to bring about exchange of ideas and experience for the general benefit of all.

Among those who addressed the club were H. M. Martin, president of the H. C. & A. I. Piercy Contracting Company, general transportation contractor; Louis Crispin, superintendent of transportation for John Wanamaker; C. R. Langenbacher, superintendent of delivery for Lord & Taylor; George Stevens, transportation engineer for the Adams Express Company, and George H. Bailey, delivery manager for the Riker-Hegeman Corporation, each explaining the systems the vogue of which they were in charge, and stating conditions and problems that were met with in organizing the work. The opportunity of learning first hand of the character of work performed, the facilities, the systems, the forms of administration, the territory covered, and the results accomplished, which information could not be otherwise obtained save at material expense and time, developed surprising interest and decided benefits. The purpose of the club is to continue these educational gatherings monthly.

EDUCATING THE COMMUNITY.

Worcester Electric Light Company Disseminating Information Promotive of Electric Vehicle Use.

The example of John E. Smith, who has charge of the electric vehicle department of the Worcester, Mass., Electric Light Company, is worthy of the reflection of those who have to do with the promotion of the use of electric vehicles. He has sought to educate the business men of the territory served by his company by the publication of statements of the practicality of the machines and the uses that can be made of them. This publicity is necessarily in generalities, for it is prepared for wholesale consumption, but Mr. Smith maintains that it is beneficial and that it attracts the attention of those who might have casual interest were not the economy of the electric machines emphasized, and the assurance of the co-operation of the company impressed upon them.

During the California state fair, that took place at Sacramento beginning Sept. 12, there was an exhibition of service wagons of all kinds, and demonstrations of capacity, etc., by the exhibitors. A considerable number of the exhibits were driven from San Francisco over the road, leaving that city together, and showing the people the practical possibilities of the machines by using them under normal service conditions. The distance between the two cities is approximately 100 miles and a stop was made at Oakland, where a night was passed. At the fair the machines were displayed in a large tent and 10 different concerns showed 15 makes of vehicles, including delivery wagons, trucks and tractors. Two of the exhibits were electric machines.

The principal business of the monthly meeting of the New York Section of the Electric Vehicle Association of America, held at the Edison auditorium, 44 West 27th street, in that city, Sept. 23, was hearing and discussing a paper on "The Value of Power Wagon Operation in the Community," read by F. J. Ryan.

The National Transportation Company has been formed at Bloomfield, N. J., for the purpose of operating a motor omnibus line between Paterson and Montclair, to afford a public service to the state normal school. The company has contracted for two vehicles that will carry 35 passengers each.

U-S-L MAINTENANCE SERVICE.

The U-S-L Service Station and Electric Garage at Buffalo, N. Y.

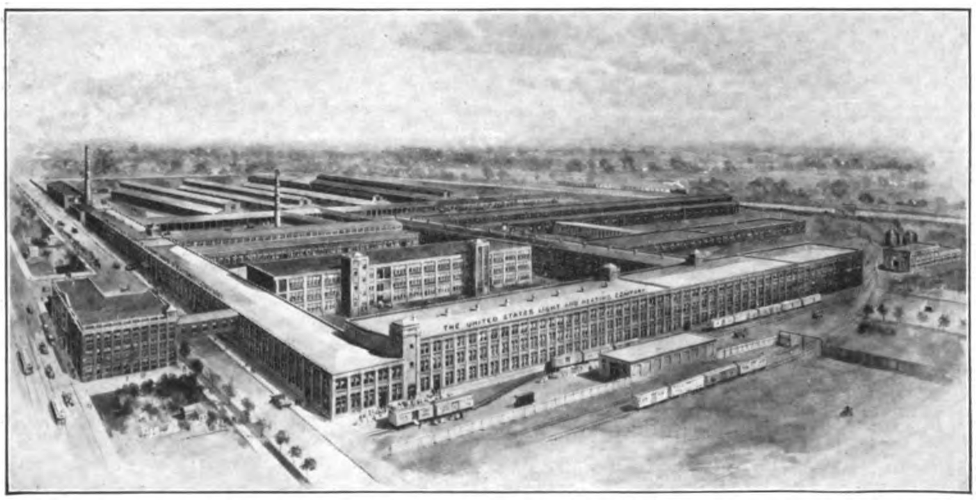
THAT branch of the U-S-L organization termed the service department, which the United States Light and Heating Company, manufacturer of the U-S-L guaranteed storage battery, has built up for the specific purpose of extending service co-operation to users of U-S-L products, is international in the scope of its operations, reaching every nook and corner of the United States and also all foreign countries where the U-S-L trade mark is found.

In the early days of electric vehicle transportation there was a scarcity of men who thoroughly understood the proper care of storage batteries and who were capable of conducting an electric garage so as to obtain the greatest number of years of continuously good battery service. This condition was only natural. It could hardly be otherwise in the inception of such an industry and the United States Light & Heating Company early recognized the great value to both itself and customers of a service department devoted entirely to instruction in the proper care of storage batteries and to keeping in touch with the every-day performance of the batteries to insure to owners that they obtain the best and most economical results.

The U-S-L service department has grown with the electric vehicle industry and now has headquarters in the United States in eight large cities: Boston, New York, Buffalo, Cleveland, Detroit, Chicago, St. Louis and San Francisco. At each U-S-L service station there is a corps of service men constantly employed in travelling through the territory which that particular service station covers, giving assistance wherever needed to U-S-L battery owners. These men are not only battery experts, but are also thoroughly familiar with the mechanism, care and operation of electric vehicles, both pleasure and commercial types. In fact, before a man can qualify for the U-S-L service department he must have a complete practical understanding of batteries and electric vehicles so that he will be able to extend the kind of service co-operation that really helps.

All U-S-L service men are graduates of the U-S-L training school, which is in session the year around at the U-S-L factory. Here the men are taken in hand by engineers and given a full course in the methods of battery manufacture from the first operation on the raw materials to the final assembling and testing. They are instructed in the care and operation of batteries and electrics and are required to do practical work in every department. Once in the field each factory graduate spends a certain amount of time under the tutelage of one of the regular service men. After this training he is competent to give U-S-L battery owners the best kind of service co-operation.

At seven of the eight U-S-L service stations depots are maintained for the purpose of assembling and repairing batteries and of keeping a complete stock of spare parts on hand for quick delivery. This does away with the delay that would occur if all assembling and repairing were done at the factory, and if the factory were the only place where spare parts could be obtained. Each depot is equipped with all the apparatus necessary for the complete assembling, repairing and testing of batteries, and because of the fact that the stock of spare parts is always complete all work is accomplished with dispatch. A great deal of



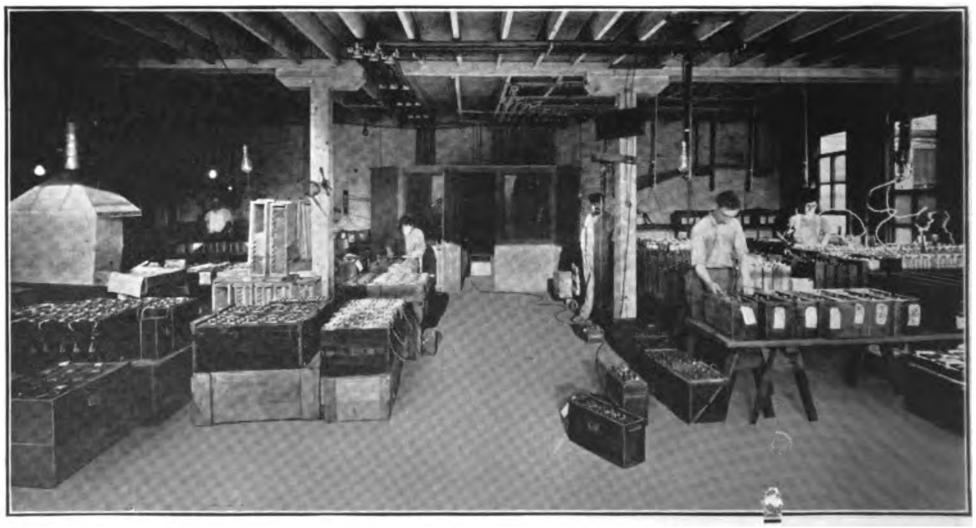
The U-S-L Plant at Niagara Falls, N. Y., Claimed to Be the Largest Storage Battery Factory in the World.

The U-S-L Branch Office at Cleveland, O.

attention has been given by the United States Light & Heating Company to the depot feature of the U-S-L service department because, especially in the case of electric delivery wagons, it is often essential that repairs be made in the shortest possible time.

The kind of service that the United States Light & Heating Company is prepared to give is especially valuable, for example, to anyone who is changing to the electric vehicle method of delivery. In such a case, if assistance is needed, a U-S-L service man gets on the ground early so as to insure that the batteries are handled properly, beginning with the first day. He keeps closely in touch with the performance of the vehicles until the garage men in actual charge understand thoroughly every point involved in the proper care of the batteries, and he is therefore ready at any time to render such aid as may be necessary. The work of the service men is supplemented by instruction books which the company sends out with all shipments of its battery equipment.

U-S-L service is available to every U-S-L customer whether he operates an electric pleasure car, one truck, or a fleet of trucks. In building up its service department the United States Light & Heating Company has endeavored to make it all that the name implies—large enough to reach all those who require assistance and capable of rendering such assistance in the most beneficial manner. Service co-operation is only of value when intelligently given and to this end the U-S-L service department has been developed.



The Interior of the U-S-L Service Station at Cleveland, O.

TARIFF TAX REDUCED.

Duty on Chassis and Finished Parts Now 30 Per Cent Instead of 45.

The new tariff law, which is now effective, places the import tax on chassis and finished parts of motor vehicles at 30 per cent. instead of the 45 per cent. tax imposed by the old schedule, and this is expected by dealers and agents of the manufacturers of machines made abroad to be of material advantage to them, as it will make possible the importation of service wagons and trucks for sale at a materially decreased price. There is no change in the tax on complete automobiles valued at more than $2000, this remaining at 45 per cent.

As the foreign machines are generally sold abroad without body equipment, it is expected that, to take advantage of the reduction in tariff, importations will be generally of the unfinished vehicles, the importers leaving to the purchasers the option of having bodies built to meet desires. So far as service wagons and trucks are concerned, however, there is no particular demand for imported bodies, and most buyers would prefer to have equipment built to specification or for special purposes. The importers of foreign machines believe that they will have a widely increased market because of the change in the tariff, and they maintain that because of the decrease in the tax there will be no discrimination made by other governments with reference to the sale of American machines in foreign markets.

The competition of motor vehicle manufacturers and agents was illustrated when the board of revenue of Jefferson county, Ala., meeting at Birmingham, gave hearing to nine different representatives who responded to an invitation to submit bids for a five-ton truck to be used in road construction. The "sellers" were so numerous that they were limited to 10 minutes each to make a "convincing argument."

SOLID TIRES FOR ELECTRIC TRUCKS.

The Essential Qualities Sought in Designing and Constructing Tire Equipment for All Methods of Vehicle Propulsion--How Efficiency Tests are Made.

By A. H. Leavitt, M. E.

IN GAS truck practise little is required of the solid truck tire except it be of sufficient resilience to insure protection to the truck mechanism, of positive application to insure permanence, and of a quality to give maximum mileage service. The solid tire for electric truck service, however, presents a different problem to the manufacturer, as not only resilience and permanent application are required, but in addition the compound must be such as to reduce the current consumption to the minimum, at the same time increasing the speed of the truck to the maximum.

The Problem of the Tire Manufacturers.

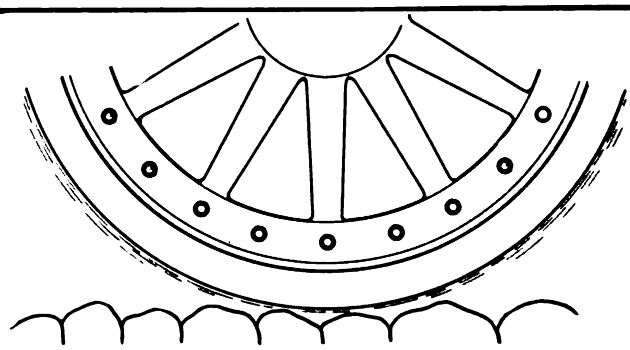
To the uninitiated this problem may appear of little consequence and the general impression of the efficient solid tire is one composed of either a very hard or very soft compound. The highest current efficiency is obtainable by equipping a truck with steel wheels and operating it upon a steel track; however, a rubber tire of excessively hard compound has been found to be efficient only under ideal road conditions such as asphalt or good hard macadam surfaces. On brick, cobble stones or rough roads generally, the vibration is extremely detrimental to the truck mechanism and the efficiency falls below that of a more resilient tire due to the slip of the wheels during the period of vibration. On the other hand, a tire built from an excessively soft compound presents such a large area of contact with the road when under load that there is a holding back or "drag", which materially reduces the speed and increases the ampere draw.

Knowing that too hard or too soft a tire will not be of the proper efficiency to meet the requirements for electric truck service, the tire manufacturer must develop a compound between these extremes, combining high current efficiency and speed. To determine the most efficient solid tire it must be taken from the laboratory and the final development made by numerous different tests, comparing various compounds and shapes.

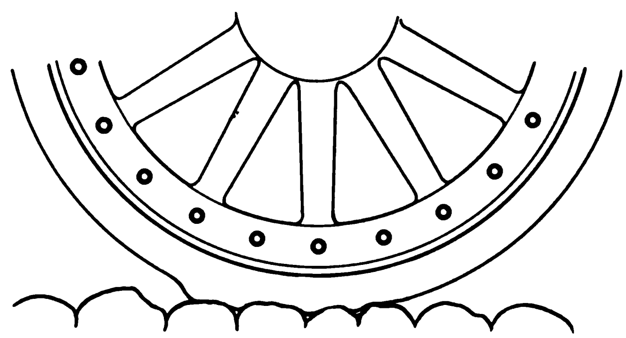
The Road Test.

Manufacturers of electric trucks have established methods of testing solid truck tires for efficiency and while few use the same test upon which their decision is based, a majority use what is termed the road test. In this test a chassis is loaded to normal capacity by means of accurate weights and driven over a measured course at a constant speed. The records kept in such a test consist of the time consumed in covering the course, volts, amperes, atmospheric temperature, wind velocity and direction, and road conditions. In some cases ampere-hour meters are used to show the total current consumed, but as a general rule fully charged batteries are used in each individual test and total watts or ampere draw used as a basis for comparison. The tires showing the greatest efficiency are those covering the course at the greatest speed and with the lowest ampere draw or watt-hour reading.

There are many chances for inaccuracies in making this test, and unless tires of differing types and makes are tested under identical conditions a fair comparison cannot be established. For example, it will be observed that an accurate comparison cannot be made if two sets of tires are applied to different chassis, even though they are of the same weight and capacity. The friction and other losses of the moving parts, as well as the efficiency of motor and batteries, might vary so



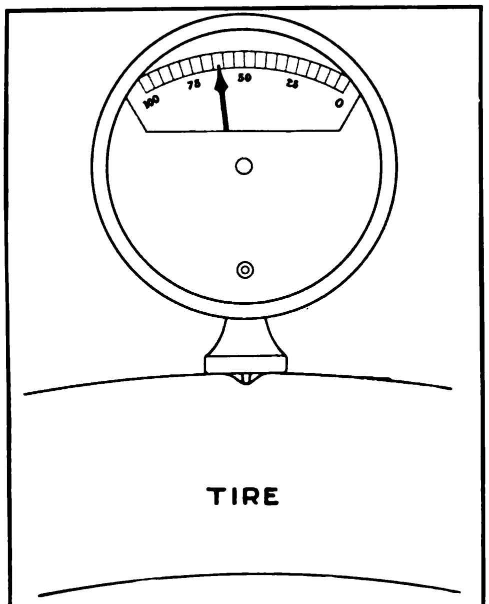
VIBRATION EFFECT ON HARD COMPOUND



"DRAG" OF SOFT COMPOUND

widely as to cause an apparent increase in power consumption not attributable to the tires.

Differences in the atmospheric conditions during separate tests will be reflected in the final results, hence accurate comparisons may be expected only where practically identical weather conditions prevail. Since atmospheric conditions also affect road conditions, the same set of tires would not show the same results if tested on a dry course as over the same route after being wet. Temperature also plays an important part in affecting road conditions, as can best be illustrated in the case of asphalt. On a hot day the asphalt would soften, causing the tire to stick or drag and con-



YIELD GAUGE

sume a greater amount of current than on a cold day when the asphalt would harden perceptibly, making a much faster course.

Wind resistance should also be constant in making comparisons, for it is obvious that more current will be required in running into a 20 mile an hour wind than one whose velocity is 10 or even 15 miles an hour.

The course over which road tests are run is usually either asphalt or good brick, and the final results show current efficiency and speed over but one type of road construction. In actual service the average electric truck meets all varieties of road and street construction and as the solid tire, most efficient on good hard asphalt, may show decreased efficiency over brick or cobble stones, and vice versa, the most satisfactory course is one including the greatest variety of paving. In this case an accurate average performance may be obtained. While the road test is theoretically the most accurate in determining the tire or tires with highest current efficiency, in order that dependable results may be obtained, the foregoing conditions must be as nearly alike as possible and the testing course should be a fair average of actual street conditions in service.

Grade Test.

The grade test consists simply of noting the length of time elapsing from the instant the brakes are released on a truck standing on a 20 per cent. grade, to the instant of passing the end of the grade. In this test time only is figured, for no current is required, and as the grade is usually artificial not much dependance can be placed upon the results. Should the same complete chassis be used in testing various makes of tires the results would be fairly reliable for comparison only, but the conditions under which the test is made are theoretically too perfect for drawing accurate conclusions with respect to results in actual service.

Coasting Test.

This test is very similar to the grade test except that distance is the basis of comparison rather than speed. In making the coasting test the truck is run at highest speed up to a marked point, at which the down grade begins. Here the power is cut off and the truck allowed to coast until coming to a standstill. Many of the variable factors are encountered in this test, as outlined in the road test, but in the main, the results are fairly accurate for comparison.

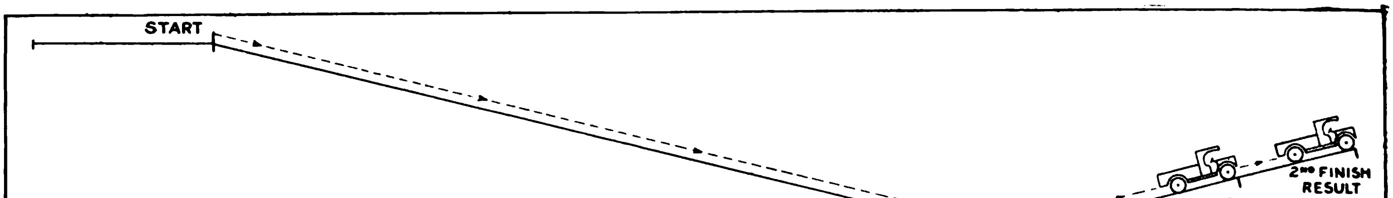
Impression Test.

This is a minor test used by one or two manufacturers and the results obtained are inadequate and unconvincing in comparing the efficiency of solid tires. The test is conducted by jacking a wheel from the floor, chalking the surface of the tire and removing the jack, allowing the weight of the wheel to rest upon a piece of cardboard or heavy paper. Upon removing the cardboard an impression of the length and width of the arc of contact is obtained. By comparing these arcs for various tires the results are supposed to show the comparative hardness. However, even these results are inaccurate for different shapes, and the test can best be used as a check for uniformity in tires of the same make and shape. Efficiency in current consumption and speed cannot be determined by this test.

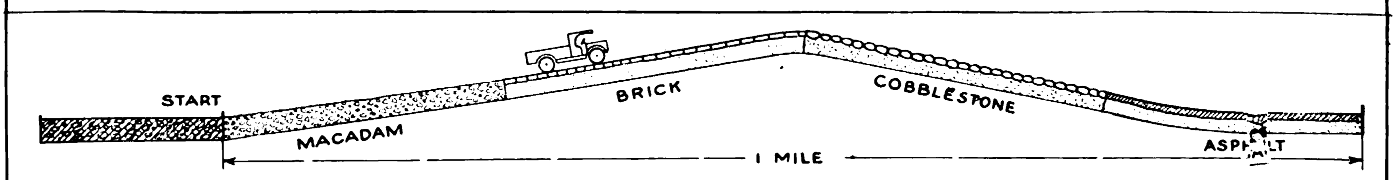
The Scleroscope.

The scleroscope, an instrument primarily designed for testing the hardness of metals, is sometimes used to compare solid tires for efficiency. This instrument has been accepted as a standard by different authorities for testing hardness of steel, and while a trifle intricate in its make up, consists mainly of a glass tube, graduated to scale, through which a weight is dropped and the rebound observed on the scale.

The results from this instrument are obtained by dropping a weight upon the tire and noting the rebound, the more resilient tires showing the greater re-



THE COASTING TEST

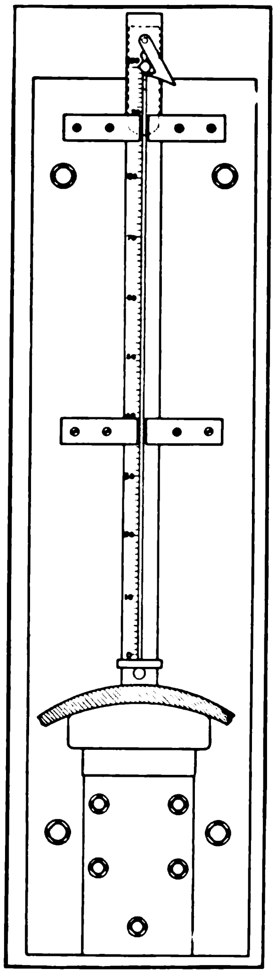


PRACTICAL ROAD TEST

bound. This test is not accurate for tires or rubber compounds, unless test pieces of the same dimensions are used. The difference in the shapes of tires, as well as the possibility that the tube may not be perfectly vertical for all tests, allows a great chance for inaccuracies. Again, the testing conditions are more nearly ideal than those encountered in actual tire service.

The Yield Gauge.

Practically everyone is familiar with the common practise of testing the resilience of rubber by biting specimens with the teeth or pressing with the fingers. Since these are very unsatisfactory methods, an instrument known as the yield gauge has been produced to take the place of the uncertain element of "feeling". By pressing the blunt end of the gauge against the tire to be tested, the amount of resistance to the pressure of a standard spring balance is shown on a graduated scale.



Modified Form of Scleroscope.

This test results in only a determination of the hardness of various tires, hence is not reliable for tire efficiency in point of current consumption, but is a fairly accurate check for compounds found to be up to requirements in this regard.

Conclusions.

From the foregoing it is apparent that the electric truck manufacturer should not base his decision for tire equipment upon any one single test, but should, so far as possible, make a careful comparison of results obtained from several. Far too frequently truck manufacturers are willing to sacrifice increased tire mileage in favor of reduction in weight. Tire manufacturers from long experience have established standard carrying capacities for all tire sizes, and the strict adherence to this standard is one of great importance in securing satisfactory tire service.

From the point of view of the truck owner, the problem is one of obtaining a tire which will reduce his cost a battery charge to the minimum, and at the same time increase his ultimate tire mileage to the maximum. Primarily the operator wants low current consumption, but it is also advisable to bear in mind the high cost of frequent tire renewals, involving also a considerable loss of time. Unfortunately, the truck operator has neither the time nor facilities for conducting the tests described above, but in view of the fact that practically all users are maintaining accurate daily records, any losses in speed or mileage a battery charge are promptly noted. When such losses occur an investigation of the tire equipment may disclose the weakness, especially if motor, batteries and transmission test up to standard.

WANT BOSTON SHOW SANCTION.

Electric Vehicle Men Protest Against Action of Governing Organization.

The annual meeting of the New England Section, Electric Vehicle Association of America, was held at Boston the evening of Sept. 25, at which time the following officers were elected: Chairman, J. E. Hunnewell, of the Lowell Electric Light Corporation; vice chairman, E. S. Mansfield, of the Edison Electric Illuminating Company of Boston; secretary-treasurer, Leavitt L. Edgar, of the Edison Electric Illuminating Company; executive committee, Day Baker, Fred M. Kimball, Frank N. Phelps, Howard T. Sands of Malden, Frank J. Stone, H. F. Thomson, Albert Weatherby, C. A. White and Paul E. Whiting.

The section adopted resolutions protesting against the refusal of the Motor & Accessory Manufacturers to sanction the exhibits that might be made by members at the annual Boston automobile and motor truck shows, and the executive committee was instructed to formulate the resolutions and forward them to the governing association.

A committee consisting of Day Baker, J. C. Codman and Business Secretary O. G. Draper was appointed to arrange for the attendance of the New England delegates to the annual convention of the Electric Vehicle Association of America, which will take place at Chicago, Oct. 27-28, and Mr. Draper was appointed master of transportation. James Fortescue, of the Massachusetts State Automobile Association, urged the section to make provision to oppose prejudicial legislation that would be proposed at the next session of the Massachusetts legislature, and maintained that it would be possible by properly directed influence to defeat, at the state election in November, some candidates who were known to be antagonistic to reasonable laws. The executive committee of the organization has charge of the campaign that will be conducted against the candidates and the measures that may be proposed.

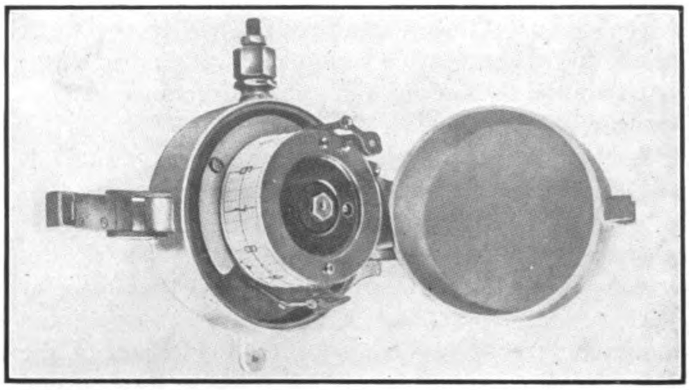
The Brockway Motor Truck Company, Cortland, N. Y., has issued a well designed booklet in which are illustrated the uses of Brockway air-cooled delivery wagons by 28 different concerns engaged in 24 lines of business, for all of which this particular type of machine is adapted.

The Coleman Gas Producer Company, New York City, will ship a motor car fitted with a Coleman gas producer to England, Oct. 15, which will be entered in the fuel competition of the Society of Motor Manufacturers & Traders, in which large prizes are offered for practical and economical operation.

VALUE OF VEHICLE HAULAGE DATA.

IN THE operation of any system of transportation there are factors that may be met with in all others, and there are others that may be peculiar to any given example, and with these variables to be considered in any analysis one must necessarily place some value upon these factors that specific and accurate knowledge may be obtained. One of the greatest difficulties experienced in the collection of haulage data has been the absence of a definite unit by which measurement may be made. In many instances endeavor has been to establish monetary value, either cents or dollars, as this standard, while others have sought to make comparison by work accomplished. But these are not sufficient because these factors vary materially.

The solution of the problem appears to be in adapting a definite standard to any business and then by comparisons with this standard ascertain whether or not the relative expense is greater or smaller. To illustrate: It is obviously valueless to regard wages as



The Recordograf with the Case Open, Exposing the Roll of Tape op Which the Record of Vehicle Movement Is Made.

a constant in any compilation when these will vary in some instances as much as 100 per cent., and, similarly, fuel expense cannot be established when not only the cost, but the character of the driving, the form of the motor, the topography, the street conditions and the loads carried all must be regarded as having material bearing upon this particular item of expense. One may go through every detail of expenditure for operation and maintenance and find that each may differ essentially.

Obviously the only certain determination can be made by first having all necessary facts with reference to one service and then making comparison—comparing the items, if there be desire to economize in this service, and the total, or, if there be a changed method of transportation, in the aggregate expense. To obtain such knowledge, however, it is necessary to have records that are standard and dependable. But in the absence of data that will permit of such comparison the only manner of obtaining precise knowledge is by adopting a system of records and then studying the work and the expense with a view to making such changes in the administration that will eliminate or reduce such costs as can be dispensed with and without impairing the efficiency of the service.

If one is to take up a problem of this character and would reach a solution that will economize in every detail one must begin with the administration and determine the expense that will include all fixed charges, such as interest on investment, depreciation, rent, heat, light, water, taxes, insurance, salaries, clerical work, printing, including real estate if a garage is owned and regarding the possible appreciation of property; the wages, fuel, lubricant, supplies, repairs, maintenance and upkeep, and with these as a measure determine if there be increase or decrease with reference to any one or all. Analyzing the cause of any variation in these items it is practical to ascertain whether or not there is economy or extravagance with reference to any or all, and to bring about such changes as will be economical.

But all this may be regarded as applicable to administration only. Yet this is not sufficient. What must be determined is the work actually performed by each delivery or haulage unit, which is only possible through following other factors, such as the loading methods, the facilities for handling freights, the conditions of making delivery, the system of routing, the manner in which the vehicles are operated, and the human element. No one form of record will show all of the facts that have been specified, and these must be divided so that they can be compiled and maintained with the least labor and expense.

Aside from administration and fixed charges, which may be applied pro rata or otherwise, the other factors are variables so far as expense is concerned, but the work performed is dependent upon conditions that must be definitely known, and which cannot be represented by office records so definitely as to be of value to others than the owner or those in charge of the transportation.

Considering the matter of handling freight and loading facilities as two conditions that must necessarily be known, and taking up the routing, the delivery, the operation of the machines and the human element, it is possible to ascertain very closely facts that have important bearing on efficiency. The record of mileage, for instance, will show distance driven and this will be of value in determining tire wear and fuel and lubricant consumption, and it is a necessary factor. It will also show the character of the routing if the hauls be anything else than straightaway and return trips. Under ordinary circumstances it is probable that the useful or productive mileage will be less than 50 per cent. of the distance travelled, for the average load is seldom carried more than half the time the vehicle is moving. In some work a load is carried the entire trip, but these instances are decidedly the exception.

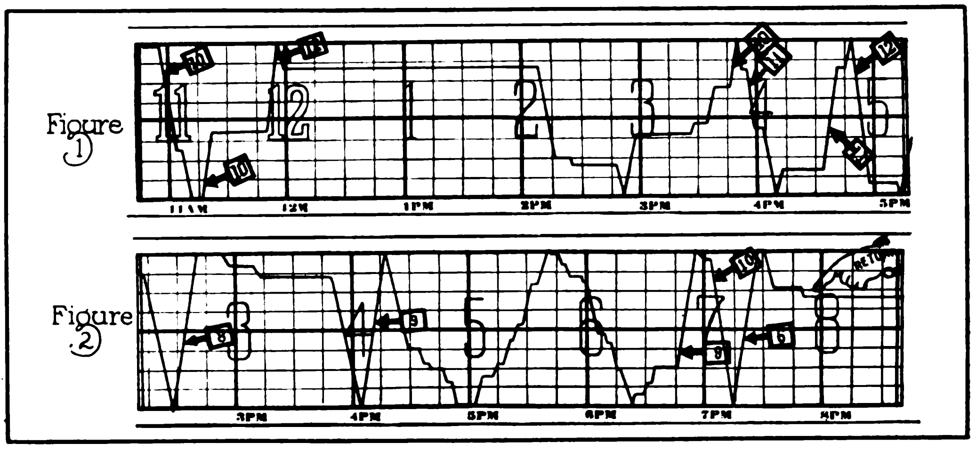
But when the vehicle has left the point of loading the manner of driving, the speed, the time taken for deliveries and the losses of time are factors of prime

importance, and these can be determined with exactness, so that the efficiency of the driver can be established beyond question. It was the necessity of affording such a record that caused the development of the Recordograf, an instrument invented by Edward A. Henkle of Philadelphia, Penn., and produced by the Delivery Supervision Company, that can be adapted to any vehicle. This device is contained in a circular metal case and is operated by a flexible shaft from one of the forward wheels, which records on a paper tape the time of starting a trip, the time of the return, the distance driven during the day and during any stated period, every stop made and the time of each stop, as well as its duration, and the various speeds during the entire time the vehicle is moving.

The record may be for a very brief interval or it may include the entire 24 hours of the day, and this will represent every fact that is desirable in establishing the use made of a machine. The record, like every other, has its chief value when it is analyzed and the work represented by it is known. That is, unless it is examined and the relation of every detail is known its value is not realized. It shows the work of the driver with regard to efficiency and safeguards the employer against imposition.

The instrument contains a roll of paper tape that is ruled longitudinally and transversely to form tiny squares, and each space between the longitudinal lines represents quarter miles, there being two miles to the width of the tape. The miles are differentiated by a heavier central lines. The spaces between the transverse lines represent quarter hours, the hours being represented by heavier transverse lines, so that each section of tape between the heavy lines is a mile in distance and an hour in time. A clock actuates a pointer or indicator transversely forward and backward across the paper tape and an indelible line is made that is at varying angles with reference to the ruled squares, or a line may be made which will run longitudinally of the tape.

The clock moves at a given speed and the tape is touched by the indicator. If the vehicle is standing the line is longitudinal, but if moving the line will be diagonal with reference to the ruled lines. Starting at any position the indicator will register on the tape, and the movement is shown by the transverse lines, so that the length of these lines shows distance driven, while the time is indicated by the heavier transverse lines. To the better illustrate: If the vehicle were driven 10 miles an hour, for instance, and at a constant speed, the line would be five times across the tape; if 20 miles, 10 times across the tape; and the angularity of the line indicates the speed. The variations of angularity show the changes in speed. Thus there are the three indications, speed, time driven and the length of stops. Differentiating these the degree of speed, the time taken for any distance and the number of stops may be ascertained.



Specimen Recordograf Records from a New York Department Store: Fig. 1, Part of the Work of a Horse Wagon; Fig. 2, Portion of the Record of a Motor Vehicle.

The company producing the Recordograf has its headquarters in New York City, and branches in Philadelphia, Chicago, Boston and San Francisco. In New York and where the branches are located the instruments are leased or rented and the supervisors of the company collect the records daily. These are examined by experts, the records analyzed, deductions made and reports made that are submitted to the owners, from which the work done by each vehicle can be learned at a glance. Where branches are not maintained the instruments are sold and the purchasers are instructed in obtaining the facts that may be useful. The company agrees to provide expert testimony in court whenever this may be necessary as to any facts that may be proven by the records.

The collection of the tape by the company and the compilation of the reports prevents possibility of error or tampering, and as the reports are purely disinterested so far as the employee or employer is concerned, and deal only with efficiency, they are in every way dependable. The record shows whether care was exercised by the drivers, whether reasonable time was required to drive a given distance, and if lengthy or unnecessary stops were made. Records covering details of use show really astonishing facts, and curious frauds, some by the drivers and others by customers, and innumerable instances of neglect, carelessness or incompetency, many of these being of such a character as to be quite beyond suspicion until the evidence had been seen.

Two Atlantic electric five-ton trucks in the service of the Kips Bay Brewing & Malting Company, New York City, which have been in use for about four months, as now used by that concern, make two trips daily to South Brooklyn, averaging from 46 to 52 miles to the battery charge. With horses but one trip can be made to South Brooklyn, and the haul is extremely long.

SUBSCRIPTIONS:
The United States and Mexico, the year $1 in advance; Canada and Foreign Countries in Postal Union, the year, $2 in advance. Fifteen cents the copy.

ADVERTISING RATES.
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

ELECTRIC VEHICLE HAULAGE.

The electric road vehicle of today represents at least 16 years of practical development. The motor has been utilized in vehicular propulsion for more than 20 years. The first electric delivery wagons were produced for a New York City firm more than 15 years ago, and since that time remarkable progress has been made in design and construction. During the period from 1897 until now the electric machine has been tested, refined and improved, and, strange as it may seem, no principle has been changed. In other words, no weakness has been discovered, but by perfecting the efficiency of the electric vehicle has been increased by several hundred per cent.

With this development of efficiency a material reduction of operating cost has been realized. This increase of efficiency and reduced expense of operation is represented in every vehicle. Concerns that have used electric vehicles for long periods have been taught by experience the need of accurate records and systems, and of the necessity of careful supervision, which have resulted in large saving. A very logical and reasonable assumption is that if a highly successful industrial or commercial enterprise approves organization and administration it does so because of business reasons, and where haulage is concerned the actual result is economy.

The experience of many firms and corporations utilizing electrics with reference to records and organization is worthy the attention of every business man, not from the fact that these machines were used, but because method and administration have developed efficiency. The electric vehicle has its sphere of usefulness, just as has any other type of machine, or the animal vehicle, to its limitations. Beyond these other means of economy must be sought.

DUPLICATION OF DELIVERY.

One of the conditions that has been developed in the recent investigation of the transportation problem in Boston is the duplication of delivery, which means that the cost is materially increased through the maintenance of so many different transportation concerns. In the suburbs of Boston, aside from the store equipments, from three to 24 established express companies are available for transporting goods regularly or casually. It is impossible to say how many different deliveries are made when all of the stores serving their customers are considered, but the number is no doubt very large. So it will be seen that these figures do not by any means represent the actual facts.

Without doubt there is sufficient business to justify the existence of these companies, but it is evident enough that while competition may establish comparatively low prices and probably satisfactory service from one point of view, the expense of maintaining them must eventually be borne by the people. The condition so far as highway haulage is concerned is not to be paralleled by any phase of industry or commerce, and systematization and organization have not been applied, at least with a view to eliminating waste and improving the service. The logical solution would be the organization of concerns that would take over the different companies and operate them as units in different localities, and by this method of operation materially improve the services and lessen the cost.

THE TARIFF REDUCTION.

What effect the reduction of tariff will have in the market for service wagons and trucks is purely problematical. Viewed practically it would appear that the advantage will be more imaginary than real, because, leaving the matter of price aside for the moment, the real demand of the purchaser of vehicles for industrial use is for attention and service, which cannot be afforded without branches and stations in the sections in which a market is found.

The business man requires vehicles that shall be useful as much of the time as is possible, and he does not care to make investment in stocks of spares that might be used eventually, but which represent actual money that could profitably be utilized otherwise. He does not care to buy what may be out of service because of the inability to secure attention, and especially when withdrawals mean actual losses, when this can be very largely insured against. Not only this, the American manufacturers are developing facilities and organizations for protecting the users of their vehicles and better results can be consistently anticipated.

TRYING TRUCKS ON ALASKAN TRAILS.

Trial of White Machine by United States Army Engineers Between Valdez and Fairbanks, On Route That Will Save Time and Expense of Travel, Shows Its Practicability.

THE use of motor wagons and trucks in some parts of Alaska, where the distances are great and the only means of travel are by horses or "mushing", is a possibility for the future, in view of the experience of the United States Army this summer, when, as an experiment, a 1500-pound White wagon was driven from Valdez to Fairbanks and return, a distance of 826 miles, in 19 days. This work was undertaken by the Alaska board of road commissioners, a military board that is entrusted with territorial development of roads within the district, and the result was in every way gratifying.

On Alaskan Trails with a White Truck: A, Road Work Along the Military Telegraph Trail Through a Typical Delta Country; B, Cliff Trail Through an Ice Canyon in the Coast Range; C, Arrival at the Mining Town of Fairbanks; D, Camping on the Guncreek Flats in the Valley of the Delta River; E, Street Scene in the City of Valdez; F, Volcanic Wilderness in the Alaska Range, Through Which a Road Will Be Built.

Alaska is a wonderful country in many respects. The summer season is short and during the period when vegetation develops it grows with amazing rapidity. The autumn season is brief and early in October cold weather is experienced. By late October the rivers are closed by ice and from that time until April the temperature is very low as a rule. Spring is the month of May and then a summer succeeds for a period of about three months. During the months of winter the snow and ice accumulates and with the advent of spring the ground thaws and becomes water-saturated, while the glaciers melt and the streams, at first torrents of icy water, subside to what may be regarded normal proportions late in the summer.

Through this country men first travelled on foot, following the paths of least resistance, generally along the water courses, and later on pack animals were used, but while today horses are found wherever roads exist, "mushing" and dog sledges are the common means of travel, the latter being used during the period when the ground is covered with snow. When the rivers are frozen the ice is generally the roadway, because it at least has the quality of a reasonably even surface, and it is more generally clear of snow, and wherever possible boats are used. On some of the rivers steamboats ply the navigable portions, and in some instances, as along the Yukon, these are the only practical means of travel.

Alaska is a United States district and is controlled as is the District of Columbia, by a commission, which administers its affairs without reference to politics or political preference, and this commission undertakes public work of all kinds, as well as supervising the general development. The road commission has been created to develop highways and means of communication between the different points with a view of having these available the greater part of the time, instead of for several months of the year, and it is now engaged in exploration and some construction work, as well as making surveys and securing engineering information which will be useful in improvements. Naturally the board has examined the trails between different points and given immediate attention to those needs that are greatest.

Valdez is one of the most southern ports of Alaska, and north of it about 350 miles is the town of Fairbanks, this being the head of navigation of the Tanana river, a tributary of the Yukon, which is within two degrees of the Arctic circle. Could this journey be made overland the journey to the interior could be reduced many hundred miles, this being usually made by steamer to the mouth of the Yukon and then up that river and the Tanana. For four years the road commission has been developing a road between Valdez and Fairbanks. There are numerous mountain ranges in southern Alaska, and there are several of these close to the coast and between Valdez and Fairbanks. The Copper river valley is the general highway from Valdez north until the ranges are passed, and then the valleys of the Delta and Tanana rivers are followed to Fairbanks. There are, of course, diverging trails. It will be understood that with the development of the highway from Valdez to Fairbanks the steamer lines will afford communication between all points along the Yukon and as far west as the mouth of that river. Now there is a telegraph line north to Valdez, and there is another that follows the Yukon easterly into the territory.

Few have any conception of the difficulties of travel in Alaska. The rivers are swollen to extreme heights in the spring and early summer, the earth is saturated with water and is soft and yielding, much of the surface of the ground is covered with alluvial deposits that cannot compact, the growth of timber and brush is often heavy, and the trails are often through canyons over bare rock and where the walls are precipitous. Frequent accumulations of snow and ice that are not dissipated until late in the summer and which in melting keep the earth flooded and consequently almost impassable, are met with. These are some of the conditions with which the road commission has to deal in its construction, and the main purpose is to build what will be practical ways, that can be maintained and will permit safe and reasonably fast travel.

One of the greatest difficulties the road commission has to contend with is the short season, but added to this are the facts that the material and supplies have to be transported and the demand for labor is such that men are not always available, nor can they be kept at work when they are attracted by the possibilities of sudden wealth.

The road commission decided to experiment with motor transportation from Valdez to Fairbanks, and practical results were desired and obtained. A standard machine, such as is used in other branches of the army service, was delivered to the road commission at Valdez July 26, and July 28 it was started overland with a load of supplies and mail for the different camps along the military trail. Some of these camps had not received mail for more than a year. Aside from a supply of fuel and tools no special equipment was carried, and the only food freighted was for use in the regions where none other was obtainable.

The departure from Valdez was in a drizzle of rain and the route was across the delta of the Valdez glacier, through the Keystone canyon, 14 miles long, where the trail is amid walls of rock and ice that at times tower to a height of 1000 feet above the Love river, the roadway being in several places a groove in the solid rock. The truck reached a camp known as Workman's that day and the following day the party passed out of the canyon and began a climb of 25.5 miles to reach Thompson's pass at the summit of the Chugach mountains. During this ascent to an altitude of 3000 feet the truck was caught in four snow slides, which, fortunately, had no results other than shovelling snow. The descent was much steeper and this brought the party into a delta, in crossing which a half dozen glacier-fed streams were forded. The stop was at Beaver Dam.

From this point for three days the truck was driven much of the time over trails that had been opened by the road commission within the past three years, and these were in every way far from being roads that could be relied upon. Much of them is a corduroy of scrub timber, narrow and very rough, so that for many miles the party passed through dense scrub and timber, and over immense beds of tundra, into which heavy objects will quickly sink to depths of several feet, but, during the winter, affords a reasonably even surface that can be driven over. These trails are in the deltas of the Copper and Gulkana rivers. Only by wading and determining the nature of the river bottoms could the truck be driven over fords. Over the trails from the Copper river valley to the fork of the Gulkana the surface in many instances was alternately ice and glacier mud, where in some places the wheels were wrapped with rope to secure traction. Many times cutting trees and blasting rock, ice and stumps were necessary before the truck could be driven on. At this point the party was in plain view of Mount Wrangell and Mount Blackburn, respectively 17,000 and 16,000 feet in height, towering skyward, and beyond this Mount Sanford, 14,000 feet high, and an active volcano was visible.

At times the vegetation was luxuriant and again the earth was mere bald rock. Trees, shrubs, brush and flowers grew in wild profusion and game was

plentiful. The Indians were abundantly possessed of fruits and vegetables. The natural beauties of the trail were such as to constantly excite admiration. The grandeur of the scenery amply compensated for the hardships experienced, from the viewpoint of the lover of nature. Following the Gulkana river for three days the party reached Paxson, in the foothills of the Alaska range, and here the military trail led straight north over the mountains, to great heights, showing large areas of the country and many beautiful lakes. Though the average climb was but six per cent., it was at times necessary to ascend grades of 16 per cent. on solid and rough ice. At this time the wheels were wound with wire cable to afford traction, but it did not entirely prevent skidding. Once the edge of a bank crumbled under the weight of the truck and only by great effort was the truck kept from a plunge into a stream far below in a canyon. Near the summit of the range a peak was seen that has the shape of a perfect dome. Nearer the top of the trail the grades were steepest and not infrequently delays were caused by washouts. Several times sharp curves could only be made by use of the reverse.

Descending the range the trail was inspected for considerable distances to insure safety of the machine, and by careful driving the Guncreek flats of the Delta river were reached, where camp was made in a field of mud and quicksand. The following day, after passing a succession of flats and marshes, a long stretch strewn with boulders was traversed, in which movement was only by very hard work for the truck. During this march rain fell. On reaching Donnelly's the first evidence of road work was seen, and for 90 miles the road traversed a surface of clay and gravel, with a fairly good foundation, through a country that was then generally devoid of snow and ice, but is rough and rugged. The road surface was soft in places, but it was a real road as compared with what had been passed over.

Reaching the Tanana river the truck was ferried at McCarty, and followed the other bank of the river to Munson's, and thence to Fairbanks, a distance of 379 miles from Valdez, the destination being reached the ninth day. The truck had made an average of 42.1 miles daily during the trip.

Three days later the machine, laden with supplies and mail to 600 pounds in excess of the normal capacity, was started on the return to Valdez in charge of Lieut.-Col. Richardson, president of the board of road commissioners, who was accompanied by Supt. Ingraham, Lieut. Egerton, Lieut. Steef, Thomas H. Parramore, Jr., and Homer Jones. The start was begun during a heavy rain and the intention was to follow the outward path as closely as conditions would allow. At Guncreek flats three days' rain had obliterated the trail for a considerable distance and there was considerable danger from quicksand. In a number of instances the machine sank into the earth so deeply as to lose traction and hard work was necessary to extricate it.

Approaching Gulkana the party met with a detachment of troops commanded by a first lieutenant sent by the War Department to investigate an alleged gold strike on the Gulkana river. The troop had six pack animals, an army field wagon and a buckboard. Six horses drew the two-ton load, which was largely food for the animals. At Willow creek the party detoured to Chitana, which added 68 miles to the trip, and this required an additional day's time. At Sheep creek, near Keystone canyon, a path of 500 yards was cut through woods to avoid a bad washout, a bridge 12 feet above water when the machine passed it before having been washed away, so fording the stream was necessary. Going through the Keystone canyon the crew had to fill many washouts in the trail with stone to pass over it. One of the discomforts of the trip were the mosquitoes and moose flies, compelling the wearing of net by the members of the party to protect their faces.

Col. Richardson stated after the completion of the trip that when the work now planned for next summer had been completed he believed the machine could go from Valdez to Fairbanks in four days. Following the experimental journey the machine was used for the distribution of mail and supplies to camps and settlements near Valdez. It will be used by the road commission and its further value practically determined.

ECONOMY OF GARFORD TRUCK.

Did Two or Three Times the Work of Horses at Practically the Same Cost.

The Garford Company, Elyria, O., builder of Garford trucks, has information from a company operating a two-ton Garford machine in transfer work in an eastern city, which in a year cost for operation and upkeep $1617.92, as against an expense of $1618.15 for a two-horse team and wagon which it replaced. At practically the same cost the truck did from two to three times the work, affording attention to custom in a territory several times larger and service to patrons that could not be done with the horses. The company handles everything from a small package to a piano, and competition impels promptness in collection and delivery, so that the service practical with the truck has materially increased the gross earnings of the company without additional expense.

The Service Recorder Company, Cleveland, O., is now represented in Porto Rico by the Atlas Commercial Company of Ponce and San Juan. The company now has factory branches in New York, Boston, Philadelphia, Baltimore, Buffalo, Atlanta, Washington, Pittsburg, Chicago, Detroit, Indianapolis, Cincinnati, Minneapolis, Kansas City and St. Louis, and it is represented in San Francisco, Los Angeles, Portland, Ore., and Seattle by the George F. Eberhard Company. The Hopkins-Benedict Company of Chicago has charge of the large volume of railroad business handled by the company.

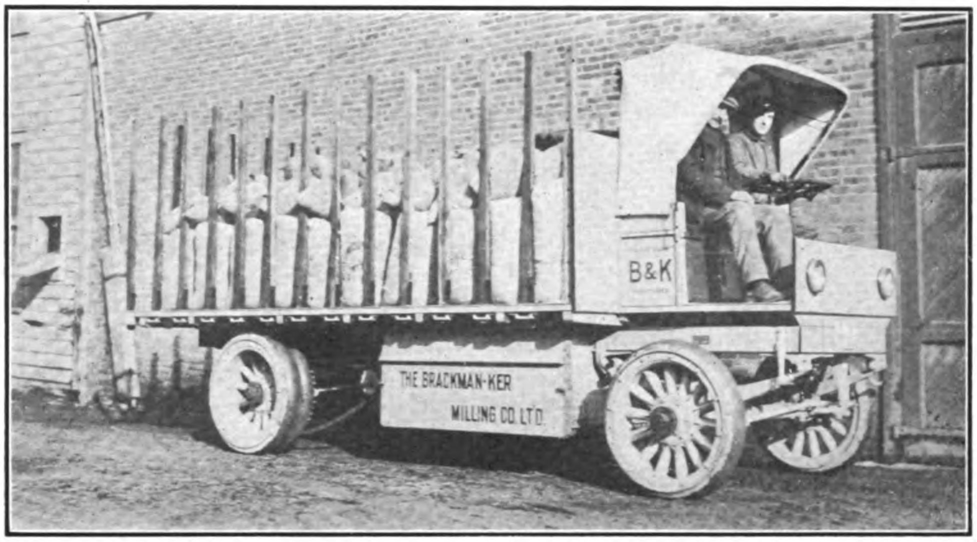
VERSATILITY OF ELECTRIC VEHICLES.

Are Utilized in All Sections of the World with Surprising Success, But Many Manufacturers Are Unwilling to Exploit Foreign Markets.

By F. Nelson Carle.

(Contributed Exclusively to MOTOR TRUCK.)

WE ALL like to see the wheels go 'round, and a great many of us have the small boy's love of the spectacular. Like the savage we want color, noise or rocket like exhibition of speed, power and magnitude.



Electric Truck in the Service of the Brackman & Ker Milling Company, Ltd., at Vancouver, B. C.

The electric vehicle is still misunderstood, perhaps largely because it is out of the ordinary. The blank thing won't act like other automobiles (and I'm afraid it never will). Like the great primal force which drives it, the electric is practically noiseless; goes along about its business without "playing to the gallery," and very seldom gets in the limelight, either through its virtues or its faults. A pair of prancing grays or the "orneriest" Louisiana mule alive can create more excitement in 10 minutes than the average electric truck will in five years.

So it comes to us more or less as a shock that a five-ton electric truck, for example, can adapt itself to any considerable variety of work. To analyze its distribution, for one thing, is to get more or less of a jolt. American made electric trucks are now used in over 40 of the 48 states, and, note this please —in Canada, Cuba, England, Germany, South Africa, Brazil, Australia, Japan, Siam and the Philippine Islands.

Portion of the Electric Truck Delivery Equipment of the El Dorado Brewing Company, Los Angeles, Cal.

When we come to trucking and deliveries we find the electric represented in 122 lines of trade. We find it hauling coal and ice as readily as groceries or beer; moving goods from the 10-cent store and gold from the banks. It pulls great wire cables through manholes, repairs overhead trolley wires, hoists safes and tows disabled cable cars; all with energy from its own battery. The electric works for the junk man with the same enthusiasm as it does for Tiffany, and just to show that it can be real careless when it likes, it capers about the streets with dynamite.

When we come down to special applications of the electric we find it in a class by itself. Indeed the electric motor has found a field of infinite expansion since becoming identified with the power wagon. There is the battery truck crane, the baggage truck, the freight truck, the electric tractor, pump wagon, street cleaner and a score or so of other electrically propelled semi-automatic devices still in an embryonic stage, but are more or less "hooked up" with the storage battery and carried on solid tires.

The advent of the electric into foreign lands is being watched with unusual interest by both American

and foreign truck manufacturers, and the eyes of merchants in distant lands are turned with no less interest toward America. In 11 days a single electric truck manufacturer received inquiries from Hobart, Tasmania; Auckland, N. Z.; Ipoh, Federal Malay states, and Pondicherry, India.

While few manufacturers will feel like attempting to develop an export business until a greater distribution has been secured in this country, the fact remains that the high grade electric possesses the same advantages in foreign cities as it does here. Electricity can be found in some very small towns, and the rates are usually very low. The problem of spare parts, tire renewals, etc., is common to all automobiles, while the handling of battery renewals is offset by practically prohibitive prices for gasoline (from 50-60 cents in the West Indies to 98 cents in Paris, if reports are authentic). At one of the recent shows was a man from Alaska who wanted an electric coal truck, because though he preferred almost anything else (so he said), gasoline was 75 cents a gallon, while he made his own "juice". He didn't get the electric though, because the manufacturer had once sent two trucks into Peru.

That the electric truck will keep pace with the steady onward march of electricity seems obvious. It has economic law behind it and a splendid "big brother" as guide. It has no hard feelings for the gas car—in fact, in older phraseology, it is much beholden to it.

INDUSTRY WANTS GOOD ROADS.

Automobile Chamber of Commerce Advocates Well Constructed Highways.

The executive committee of the Automobile Chamber of Commerce at a recent meeting, after consideration of the subject of good roads in general and the indorsement of the Lincoln Highway project in particular, resolved to approve the proposition, and made a declaration of approval of the principles adopted by the good roads committee of the organization at a meeting of that committee at Detroit.

The executive committee of the chamber has adopted the following: "That we realize thoroughly the necessity of improved road conditions * * * and we believe it is advisable to adopt the construction that, after thorough investigation, will give the greatest permanency, first cost being of lesser importance," which was a resolution adopted by the commercial vehicle committee, which represents 95 of the leading motor vehicle manufacturers of America.

In the announcement of its attitude and policy the Automobile Chamber of Commerce states that the solution of the problem of road building has been given much attention by the motor vehicle industry, emphasizing that many authorities have pointed out that roads are worn very rapidly and the cost of keeping them in even passable condition has increased enormously. Reference is also made to large state bond issues for the construction of highway systems when so far as known no specification has been made for a moderate cost road for which is claimed a life of more than from five to 10 years without resurfacing, even when repairs are made each year. The statement is further made that radical and immediate changes in road building methods must be adopted if the country would keep pace with its industrial, commercial and social needs. In connection with this is the statement that France is to spend $50,000,000 during the next 10 years tarring 6000 miles of roads in addition to an expense of $270 a mile for maintenance and repair to 25,000 miles of national road.

"OIL TOPPINGS," A MOTOR FUEL.

Waste Oil from Petroleum Refinery Develops Large Economy in Trial.

A test of "oil toppings", a refinery product that has until now been regarded as practically valueless, was made by O. W. Kern, who drove a 1500-pound KisselKar delivery wagon from Los Angeles, Cal., to San Francisco, carrying 2000 pounds, in 24 hours and 40 minutes, seems to show that this oil may be commercially useful and that it is an extremely economical fuel as compared with gasoline and other hydrocarbons. The trial was made to demonstrate a new carburetor, which has been designed to carburet kerosene and similar heavy oils, and with a view of showing its qualities the "oil toppings" was used.

"Oil toppings" has been used for a long time for firing boilers and furnaces, and it has a specific gravity of 38.5 Baume as against 59.7 for commercial gasoline, which indicates a much greater density. The carburetor in which it was used is practical, it is stated, with all oil fuels and without change. The cost of "oil toppings" was rated at Los Angeles as three cents a gallon, which shows that consuming 46.5 gallons for the drive of 472 miles, the total expense for fuel was $1.40 and the consumption was one gallon to each 10.15 miles. It is maintained that the "oil toppings" is productive of more heat units and consequently greater power a volume than any of the lighter oils or distillates. The carburetor used is the invention of Harry Miller of Los Angeles. "Oil toppings" has a specific gravity of 41 at 85 degrees of heat and is slow in evaporating and sluggish in combustion unless used with a carburetor that thoroughly vaporizes it. According to the tests made the carburetor gave satisfactory results with "oil toppings", kerosene, a mixture of equal parts of kerosene and distillate, distillate, a mixture of equal parts of distillate and gasoline, and gasoline.

A delivery wagon that will weigh 750 pounds and have a load capacity of that weight is to be built at Detroit, Mich., by the Internal Gear Drive Company, from a design perfected by Albert F. Mais, a well known engineer. Benjamin Marks is associated with Mr. Mais in the new venture.

PRACTICAL CO-OPERATIVE PROMOTION.

Recognition of the Electric Vehicle As a Material Factor in Highway Transportation the Result of the United Endeavors of the Industry and Allied Interests.

By Harvey Robinson.

CO-OPERATION between manufacturers, dealers, supply men, users and electric power interests has been the means of establishing the electric vehicle in the position it now occupies. It has brought the storage battery vehicle from the comparative obscurity of only a few years ago to a position where it is the dominating influence in many fields of delivery.

Harvey Robinson, Secretary, Electric Vehicle Association of America.

Yet even with this accomplished there still remains a great work to be done before the electric will have been established in its relations with other types of delivery wagons. This calls for still further co-operation, and even now the forces are uniting for a campaign whose influence will be felt throughout the country. In its national affairs this co-operation is brought about through the Electric Vehicle Association of America; back of this is the local co-operation between the central stations and vehicle selling agents in each city, and then back of that is the individual advertising of each manufacturer.

Last year the national association carried on a $50,000 advertising campaign that reached millions of people a month. Forty-five mediums were used, and the "ads" were directed to the readers of popular magazines, fashion and social publications, central station bulletins, auto trade journals, physician's journals and a miscellaneous selection of trade publications. Practically the same methods will be followed during the campaign of 1913 and 1914, except that the scope will be wider.

In New York, we who are trying to promote the electric vehicle are confronted by a problem backed up by 120,000 horses. However, motor trucks are making steady headway against the prejudice that for a long time refused to consider anything but horseflesh, where hauling was to be done. Now there are approximately 5000 motor trucks in New York and of these 1626 are electric. These figures are from the official record of the New York Edison Company of Aug. 1. In addition to the trucks there are 525 pleasure cars, making a total of 2151 electric vehicles in New York.

Development by Co-Operation.

It was perhaps 10 or 12 years ago that electrics were first used in New York. From the beginning until 1911 electric vehicle sales were few and far between, for in that year there were but 1200 in the city. When the period over which those sales were spread is compared with the two years in which the sales increased to more than 2100, the value of co-operation may be seen.

It was in 1909 that the New York Edison Company began its co-operation with the local electric vehicle dealers, and it was in the same year that the first steps were taken to bring about the organization of the national body, the Electric Vehicle Association of America.

It has been estimated that by the year 1918 there should be in operation in the United States 300,000 commercial vehicles, and it is argued that by reason of their adaptability to city usage electric trucks should constitute 65 per cent. of this total, or 195,000 machines. Certain it is that without co-operation between the central station company and the manufacturers of the electric vehicle, such a substitution for horseflesh will not be realized.

While much has been said, and central stations have been convinced, of the desirability of electric vehicle business, perhaps too little has been said and too few suggestions offered the central station company as to how it may do its part in the necessary co-operative movement.

Planning for Local Campaigns.

It is advisable that the central station company seeking to build up an electric vehicle business first establish what may be called an "Automobile Bureau." The bureau may in the beginning consist of but one man whose position may be dignified by the title "Automobile Engineer" or "Manager, Automobile Bureau." All automobile inquiries coming to any other department of the company should be referred to the automobile bureau and the bureau held responsible for the answer given. The bureau should be advertised as a source of information for the general public and an effort should be made to arouse confidence in the ability and willingness of the central station company to supply the service of a consulting engineer free of charge.

Four years ago the New York Edison Company established its automobile bureau, and the man placed in charge was instructed that his duty was to co-operate in every way possible with the electric vehicle manufacturers who were selling in New York territory.

After the bureau became acquainted with all local

electric vehicle selling agencies, it set about the task of getting in touch with all local users of electrics. A list of all New York City automobile registrations was obtained from the secretary of state, the electric vehicle owners selected therefrom and listed on cards. A list of customers taking service from the company for charging purposes was next obtained. Calls were then made on all persons whose names appeared on either list, the preliminary record was checked, and a permanent record established. This record is kept on cards which show the name of the owner of the car and his address, the make of the car, where it is garaged, and the source of the charging current, whether Edison service or a private plant.

This list of vehicle owners is kept up-to-date by daily reports from the state automobile registration bureau, and whenever a new registration appears the car owner is interviewed, the purpose of the automobile bureau explained and its services offered. The bureau aims to keep in touch with the operation of every electric in the city, and whenever possible performance and cost data are obtained. A call is made at least once annually on every user in the city. Owners of cars and electric vehicle manufacturers were advised by letter that the company had established an automobile bureau, and stood ready to assist in the care and operation of electric vehicles.

Need of Charging Stations.

The next very important step was the establishment by the company of 22 two-outlet charging stations throughout the city. This network of emergency charging stations covers the city very completely, and it never happens that a vehicle wanting a boost is a too great distance from a supply of charging current.

The automobile bureau of the New York Edison Company is now composed of eight people, one of the number being a lady demonstrator, making demonstrations and giving driving lessons in any of the cars offered for sale in the city. One of our men is an office engineer, who collects and compiles statistics and all performance and cost data he can get hold of. He supplies engineering advice to our service men, and our salesmen, at times going out on special cases himself.

If the electric vehicle purchaser will permit, the bureau will direct the installation of the necessary garage apparatus, and give advice as to proper maintenance of the vehicle. If the purchaser does not wish to care for the car himself, he is supplied with a list of nearby garages where satisfactory advice may be obtained. In this manner the service of the bureau is two-fold, first by arranging garaging facilities for the new car, and secondly by increasing the business of the garage man who is trying to earn a lower rate.

Reaching the Business Men.

Another duty of the bureau is to select and maintain a list of New York business houses now using horse drawn vehicles and whose volume of business handled seems to warrant the adoption of a more economical mode of transfer. This list is circularized at intervals and attention is drawn to the advantages to be derived from the use of electric trucks. A reply to one of the letters being received, a representative immediately calls and determines the requirements of the case, submitting interesting performance data, and figures on cost of operation and maintenance. He also has with him a list of satisfied users of electric vehicles. With the prospective purchaser's permission his name is sent by letter to the local representatives of the different electric vehicle manufacturers, with the request that descriptive literature be sent and followed by a salesman. The automobile bureau becomes acquainted with the salesmen on the case and keeps in touch with the progress made, giving information where it is wanted on the cost of charging current and the necessary charging apparatus.

The company spends a goodly part of its advertising appropriation on electric vehicle publicity. Space is purchased in both newspapers and magazines, and each advertisement carries the names and addresess of all electric vehicle selling agencies in the city. Copies of our advertisements are always sent to vehicle manufacturers, irrespective of whether they are represented in the city or not. It is interesting to note that two years ago there were but eight or nine manufacturers represented in New York, while at the present writing there are 21 agencies or branches.

Creating Locality Interest.

The central station company should take the lead in the formation of a local electric vehicle association. Meetings might be held monthly, or oftener if desired, and everyone in any way interested—users, prospective users, manufacturers and selling agents—should be invited to hear the reading of papers prepared by competent men and to join in a discussion which may follow. An association may also readily undertake the arrangement of what may be called public demonstrations or publicity stunts. The "get-together" spirit must be worked up. Interchange of experience and ideas will make for better progress.

An encouraging indication of the progress of the electric vehicle in commercial service is the fact that within the past two years a number of gasoline truck manufacturers have added, or are arranging to add, electric cars to their output. Gasoline car manufacturers are noted for progressiveness and it is evident that these concerns have read the signs of the times and have moved accordingly.

During the year 1912 the New York Edison Company supplied charging current to about 1000 electric vehicles, the aggregate current consumption thereof being 6,012,309 kilowatt-hours. Today we are supplying current to 1335 electrics, or 62 per cent. of the total number operating in the boroughs of Manhattan and Bronx. Consumption is at the rate of 8,000,000 kilowatt-hours a year. More than 300 cars have been added since the first of this year to the total number of electrics operating in New York, and it looks as though the end of the year will see the total increased by between 700 and 800.

An analysis of the total number of all kinds of motor trucks operated in New York City shows that 75 gasoline truck manufacturers represented in New York City have sold 2300 trucks, or less than 31 trucks a manufacturer, while 14 electric truck manufacturers represented have 1850 electrics, or 132 a manufacturer.

While manufacturers of electric automobiles and central stations are to be congratulated upon what progress has been made during the past two years, much work still remains to be done before the electric vehicle may even divide with the gas car the country-wide business that is now in sight.

ELECTRIC VEHICLE TIRE EQUIPMENT.

By T. H. McGiehan, General Manager, Motz Tire & Rubber Company, Akron, O.

IN PERFECTING an ideal tire for electrics two fundamental qualities must be incorporated in order to make a dependable tire. These properties are resiliency and durability, and naturally they are both dependent upon many variables such as compounds, shape of tread and method of fastening.

The most important is the general construction of the tire. The tire must be designed so that the minimum amount of energy is consumed in propelling the vehicle. Conservation of power is the one most important factor in the maintenance of an electric car.

Therefore the resilient and durable electric tire that covers more miles on a battery charge is the only tire for electrics. Every time a solid tire strikes a road obstruction it takes added power to lift the car over, but when the tire absorbs the shock all the power is used in carrying the car in an onward instead of an upward direction.

Not only are cushion tires far superior to solid tires in saving fuel consumption, but they are also an important factor in prolonging the life of the mechanical parts of the machine. In this comparison the pneumatic tire comes in for an equal amount of credit, but the Motz cushion tire goes one step farther; it is trouble proof.

When you consider that the electric pleasure vehicle is the most popular car for women because of its ease of manipulation, then you can readily realize why practically 90 per cent. of the electric vehicle manufacturers specified Motz cushion tires for their 1913 equipment. Women cannot and should not be expected to repair a blow-out or puncture any more than they should be expected to crank a motor. It was essential that the manufacturers equip their machines with self-starters. Naturally the woman buyer was partial to a machine with this equipment. This made driving for her much more of a pleasure as it overcame a large amount of trouble.

Therefore it was up to some one to invent a tire that had all the qualities of a pneumatic tire and with one thing more—puncture proof. In being able to produce a cushion tire that contained the resilient qualities of a pneumatic and moreover the durability of a solid tire, a wonderful achievement was accomplished in the tire industry.

In connection with this it might be said that throughout the many experiments of attempting to produce an efficient pneumatic tire for electrics that would consume less power than the regular pneumatic tire for gasoline cars, many difficulties presented themselves which necessitated either the sacrifice of durability to make the tire faster or the sacrifice of resiliency to make the tire more durable. In the cushion tire for electric vehicles both of these qualities are contained without sacrificing the one to obtain the other, which affords an all-around, efficient and trouble proof electric tire.

NEW HORNER TRUCK.

Detroit-Wyandotte Motor Company Organized to Produce Horner Models in Grabowsky Plant.

The Detroit-Wyandotte Motor Company, Detroit, Mich., has been organized with George A. Horner as president, and associated with him are John Baker, Jr., as sales manager, R. A. Parker as assistant sales manager, Morris Pierce as service manager and William Parkin as chief engineer. The company has acquired the plant of the Grabowsky Power Wagon Company and the purpose is to produce a machine that will be a refinement of the Grabowsky design. The Horner truck will have increased accessibility, more power, and will be considerably simplified. The company will conduct a service department for the benefit of owners of Grabowsky machines. Mr. Horner was the manager of the Grabowsky Power Wagon Company during the period it was conducted for the benefit of the creditors.

GAS PRODUCER TAXICABS.

Chicago Concern Is to Give Coleman Device a Test in Active Service.

The Owen H. Fay Livery Company, Chicago, Ill., has made contract for the equipment of 50 of its machines in general passenger service in that city with Coleman gas producers, and it is expected that these will be ready for operation by the first of the coming year. The company tried kerosene for fuel without the degree of success expected, and believing that there would be more or less loss of business in the event of starting delays, decided to adopt the gas producers, which utilize coal for fuel. This is in line with an endeavor to economize the cost of operation, and the belief that, in all probability, there will be no decrease in the cost of gasoline.

POWER ECONOMY FROM BALL BEARINGS.

Practical Application of These Journals in Electric Vehicle Construction—Their Relation to Efficiency and Conservation of Energy Through Minimized Frictional Loss—Forms That Are Commonly Used in Practise.

By Victor W. Page, M. E.

THE electric automobile differs essentially from those propelled by steam or gasoline engines, because it derives power from stored energy obtained from a charged reservoir which becomes depleted in direct ratio to the demands made upon it. The electric vehicle designer is confronted with a problem of magnitude which does not receive the same consideration from designers and engineers associated with the development of the gasoline automobile, and that is to secure maximum efficiency of power producing and transmitting elements in order that the charge of electric current available in the battery be conserved to the utmost.

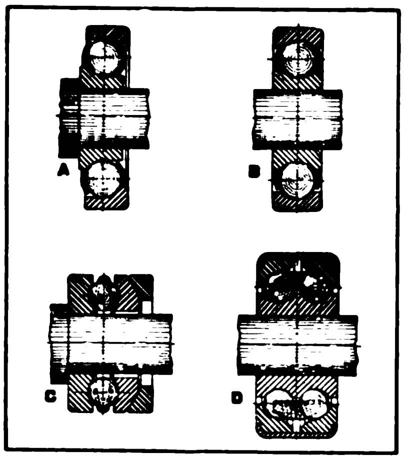


Fig. 1—Types of Ball Bearings That Have General Application: A, Cup and Cone or Adjustable Type; B, Single Row Form for Radial Loads; C, Ball Bearing for End Thrusts; D, Double Row Bearing, Combined Radial and Thrust.

In the gasoline automobile the power is generated as needed and as long as the engine functions properly, the energy required to propel the vehicle is available. The matter of securing maximum efficiency is important, but is not given as careful consideration as it must have in those types of vehicle depending upon stored power. The real power capacity of any automobile is that delivered at the traction wheels, not the amount of energy produced by the prime mover or available in watt-hour capacity of storage battery. Before the power can be applied to driving the vehicle it must pass through a motor, which transforms the electric current to mechanical energy, after which it is transmitted by mechanical means, such as reduction and drive gearing, to the traction members. There is an inevitable loss in converting electrical to mechanical energy, but this cannot be compared to the large losses due to friction and power absorption by gearing, etc.

Purpose of Discussion.

The writer proposes to confine himself to the largely preventable friction losses in bearings and will endeavor to make clear how a reduction of friction by using properly selected anti-friction journals of the ball type will increase the aggregate efficiency of the vehicle to which they are fitted. It is common knowledge that a plain bearing has more friction than one of the ball or roller type, and it is also conceded that the ball bearing is the most efficient of all because it has the least friction. An impression prevails in some quarters that bearing friction is a matter of little moment and that there is so little difference between the various types that all anti-friction bearings will save approximately the same amount of power. Careful laboratory tests show that this impression is erroneous and based on a misconception which is fostered to a large extent by those interested in the promotion of the less efficient types of bearings.

Bearing Type an Important Factor in Design.

The average electric vehicle owner or mechanics associated with him have full knowledge of the main parts of the mechanism, but some of the components are apt to be overlooked because they are not as conspicuous as others and may be considered unimportant. Among these parts are the bearings used for supporting all rotating shafts and those employed in the wheels supporting the vehicle weight. To many, the

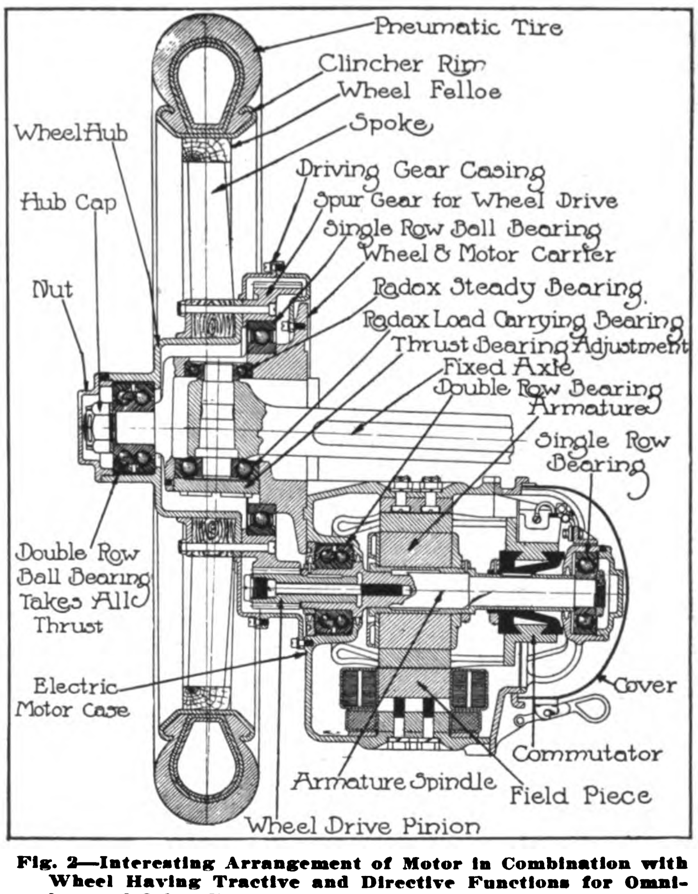

Fig. 2—Interesting Arrangement of Motor in Combination with Wheel Having Tractive and Directive Functions for Omnibus and Other Urban Use—Note Use of Ball Bearings at All Points.

type of bearing is of little concern as long as it does its work fairly well, but there is a great difference between several types of bearings used and it is important to know which are the most efficient at a time when minimum cost of operation and maximum efficiency and endurance are important considerations in determining the suitability of the various vehicle types for commercial work.

Friction of Bearings Compared.

A number of experiments have been made with fine instruments to determine the relative friction of the various forms of bearings. The results of these experiments demonstrate that the coefficient of friction of a well oiled plain journal will vary from 2.5 to five per cent. of the load applied. The friction of roller bearings has been determined by Prof. C. H. Benjamin to be about one-half or two-thirds that of the plain bearing, the coefficient ranging from 1.75 to three per cent., whereas a ball bearing, which has a coefficient of friction of but one-tenth of one per cent., has about 1-20 the friction of a roller bearing and from 1-25 to 1-50 of the friction of a plain bearing. Other authorities are somewhat more conservative in regard to friction of bearings, but an analysis of most of the accept-

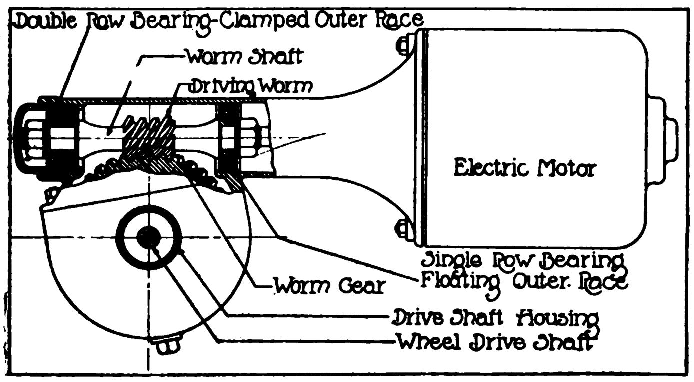

Fig. 3—Combined Power Producing and Driving Element Using Ball Bearings to Support Worm Shaft.

ed published literature and reports of tests has supported the writer in considering the average coefficient of four per cent. for plain bearings, one per cent. for roller forms and two-tenths of one per cent. for ball bearings. This means that a plain bearing takes 75 per cent. more power than a roller bearing and 95 per cent. more power than a ball bearing.

The following simple formulae will enable anyone familiar with ordinary arithmetical processes to determine the amount of power needed to overcome friction of plain and anti-friction bearings with sufficient accuracy to make intelligent comparisons between them:

For plain bearings: $H.P. = .0000003 \times P \times d \times rpm.$
For roller bearings: $H.P. = .000000075 \times P \times d \times rpm.$
For ball bearings: $H.P. = .000000015 \times P \times d \times rpm.$

In the above let P equal load in pounds; d represents diameter of journal in inches for a plain bearing and diameter of circle drawn through the centres of the balls or rollers of an anti-friction bearing, while rpm represents revolutions per minute of shaft supported by the bearings under consideration. The constants are based on the values previously given for coefficient of friction.

To show the practical application of the formulae, let us consider a bearing three inches in diameter under a load of 5000 pounds at a speed of 100 rpm. This would correspond to the load on one 36-inch rear wheel of a loaded three-ton truck making a speed of 10 miles an hour.

$H.P. = .0000003 \times 3 \times 5000 \times 100 = .45$ for plain bearing
$H.P. = .000000075 \times 4 \times 5000 \times 100 = .15$ for roller bearing
$H.P. = .000000015 \times 4 \times 5000 \times 100 = .03$ for ball bearing

It will be evident that the plain bearing will take nearly .5 horsepower, a roller bearing will need .15 horsepower, while a ball bearing will consume but .03 horsepower under the same conditions of load and speed.

Ball Bearings Show Positive Saving in Current.

Changing this into watts will give some idea of the saving in electrical energy if anti-friction bearings of the ball type are used. If one considers an efficiency of 85 per cent. to allow for losses in motor windings and wiring, there will be 878 watts drawn from the battery for each horsepower delivered by the electric motor. To overcome the friction of the one plain bearing considered as an example the motor must consume 395 watts, whereas the ball bearing will necessitate the use of but 26.34 watts. When one considers the number of bearings in an electric automobile and that all of these require the expenditure of power to overcome their friction, it will be apparent that a material increase in effective radius of action a charge of battery may be obtained from a ball bearing electric vehicle over exactly the same construction fitted with bearings that consume more power.

Why Ball Bearings Have Little Friction.

The ball bearing has less friction than the roller bearing for several reasons, the most important being that the rolling members are true spheres and that there is no tendency for ball deformation to produce the wedging and disalignment so prevalent with rollers. The balls of a properly designed bearing bear at two points diametrically opposite. Even under deformation, due to the load, these points do not increase materially in area and thus cause spinning or sliding of the balls, as the natural tendency of the ball to roll is not interfered with. A ball may turn around in any direction on account of its spherical shape, and there is practically no friction between the balls and the separators because this member is not employed to restrain ball rolling. The two areas or zones of contact of a ball are always diametrically opposite and there is no condition in the ball bearing with properly formed raceways that will produce friction under practical service conditions.

Those who favor roller bearings advance the contention that a roller bearing has more surface than a ball bearing. This is true, but the same argument could apply to the plain bearing, which has infinitely more surface than that present in either a ball or roller form. It will be seen that the amount of surface avail-

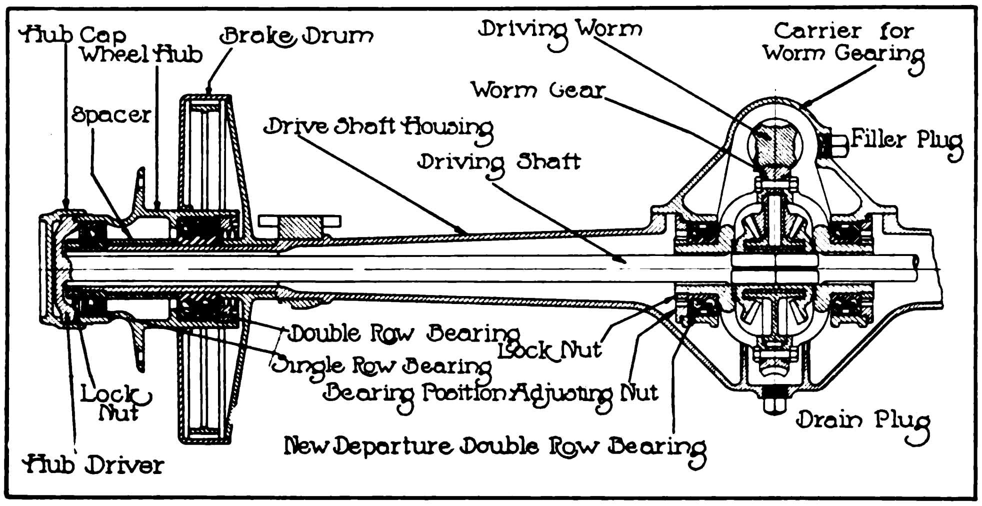

Fig. 4—Worm Drive Axle of the Full Floating Type Suitable for Electric Vehicle Service on Account of Ball Bearing Support of All Revolving Load Carrying Members.

able to support the load is not the only condition that makes for bearing efficiency. In reality the form of bearing with the greatest surface is that which experience has demonstrated consumes the most power, wears out the quickest and gives the most trouble. The modern business man would not purchase an automobile that was mounted entirely on plain bearings. With the present charges for electric current, lubricating oil and repair work, such a machine would be much too expensive to operate. A power plant of about twice the capacity of that now used in the car equipped with anti-friction bearings would be needed, and the hill climbing ability and general capacity would be much lower than that of the more efficient vehicle with but half its power. The matter of friction is, then, one that must be considered important. It is apparent that the forms of bearings which have the least friction will be the most economical and satisfactory in service. Not only will they provide superior speed or greater mileage for a given amount of electricity, but they will have much longer life, and will be practically free from trouble, because the most accurately built bearings are those which have the fewest weaknesses.

It is contended that ball bearings must be more accurately made and fitted than are either roller or plain bearings, and that as a result they are more delicate and not so suitable for general application. It is true that the component parts of a ball bearing are very accurately machined. In fact, the balls are machined so closely that those in any one bearing do not differ from each other, either in sphericity or adherence to standard size, by more than one-tenth of one-thousandth of an inch (.0001 inch). It is not difficult to produce spheres, commercially, to these limits, while it would be extremely difficult to manufacture rollers in a commercial manner that would be so uniform in size. It is this care in manufacture that makes ball bearings superior as friction eliminators. The closely fitted, accurately machined parts, which have no waste movement or lost motion, insure that the load will be distributed more evenly than would be the case if the bearing were made without this extreme accuracy. It is not true, however, that a ball bearing is delicate or not satisfactory for general application. When properly selected they will carry any load that any other form of bearing will withstand successfully, and will do it with less consumption of power than any other form.

Ball Bearing Forms Used in Practise.

The various forms of ball bearings are shown in illustration, Fig. 1. That at A is a so-called adjustable type, having the load line at an angle so that it is precisely like the tapered roller bearing, in that it is capable of withstanding a radial and a thrust load or the angular resultant of these two. It also shares with the tapered roller bearing the disadvantage that it can take angular or thrust loads from one direction only, and that is the one which tends to bring the bearing members more firmly into contact.

The bearing shown at B is the conventional single-row annular form that has been widely applied. This type will resist radial loads and can also withstand a small amount of end thrust, though conservative bear-

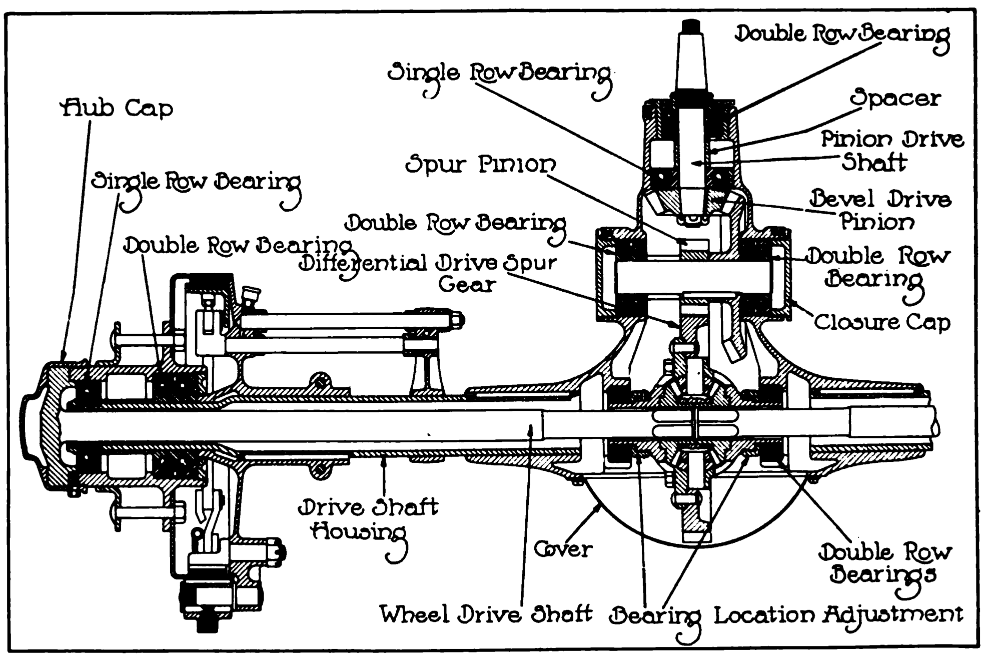

Fig. 5—Double Reduction Axle of Full Floating Type for Electric Vehicles.

ing manufacturers do not recommend it for this purpose. The radial capacity of this bearing is higher than that of any other single-row form and it operates with less friction loss than any other commonly employed type of bearing regardless of design. The bearing at C is intended to take thrust loads only and is generally used in combination with the radial form shown at B.

At D a unit bearing is shown which is capable of taking end thrust from either direction and sustaining a radial load as well. This form of bearing, owing to the two rows of balls, has a higher radial capacity than a single-row form of equivalent bore and outside diameter, and at the same time can be employed to successfully replace any other combination of bearings necessary to do the same work.

If bearings of the so-called adjustable type are used and the loads are applied as angular resultants from both sides, two of these bearings must be used and they must be mounted in such a way that the tendency

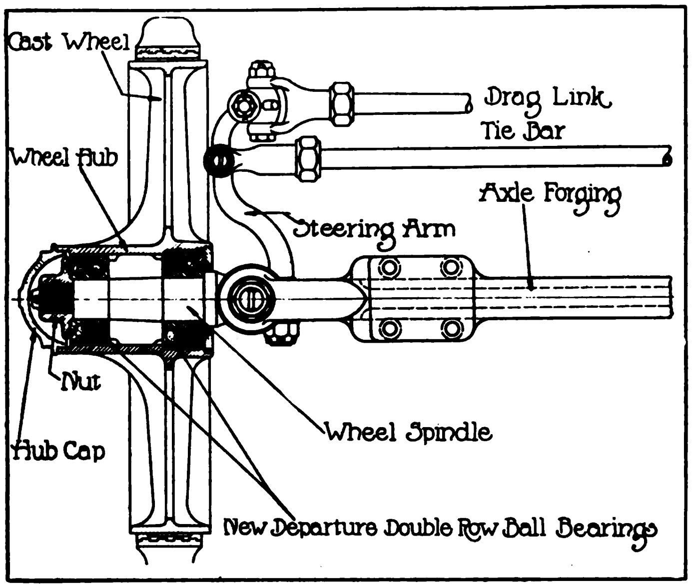

Fig. 6—Front Wheel Assembly of Heavy Electric Truck Axle Showing Double Row Ball Bearings.

of the loads applied to them will be to bring the balls and races firmly together. If one utilizes the forms of bearings which have been devised to carry radial loads only, it is necessary to add a distinctive form of thrust bearing to resist the end thrust. For this reason the double-row form of ball bearing having angular load lines is without doubt the most satisfactory bearing for general application, because it is a complete unit capable of withstanding radial loads in excess of the capacity of any single-row bearing of the same bore and outside diameter, and includes a high degree of resistance to thrust stresses from either direction at the same time. This one unit will replace successfully any combination of thrust and radial bearings, whether of the plain or anti-friction type, in any application.

Where Ball Bearings Are Used.

The main points where ball bearings can be used to advantage are at the motor armature bearings, on the power transmitting gear shafts and in the road wheels, both front and rear. The drawings presented are of actual applications that have been used successfully in electric vehicle practise and are interesting in that they show designs of various essential components as well as the methods of using ball bearings at the important bearing points. Considering first their application to electric motor armature support, the reader's attention is directed to Fig. 2, which shows an interesting method of motor suspension and wheel drive following foreign practise. The motors are applied directly to the wheels and all four wheels are used for driving as well as steering. The motor is attached to an extension of the wheel carrier in such a manner that the entire motor and wheel assembly oscillates when steering. Owing to small ground clearance this method of motor suspension is suited only to vehicles intended for city use, such as omnibuses, heavy trucks, etc.

An internal spur gear is secured to the wheel and this is driven by the spur pinion attached to the motor armature shaft. The motor shaft is supported on ball bearings, one of the double-row form being placed next to the spur drive pinion, while a single-row bearing suffices to support the other end of the armature. The wheel carrier is mounted on a large ball bearing of the thrust type and steadied by a smaller one above the axle. This insures easy steering. The wheel itself revolves on ball bearings, the outer one, or double-row type being depended on to carry its share of the radial load and take end thrusts as well. The large inner bearing is a single-row type subjected only to radial loads.

Current Saving in Ball Bearing Motors.

In connection with the use of ball bearings for motor armature shaft support, let us first consider the saving of current made possible by their use. A series of tests were made to determine the relative efficiency of a three horsepower motor with armature mounted on plain bearings in one instance and on ball bearings in the other. The plain bearing motor was but 75 per cent. efficient, while the ball bearing motor showed an efficiency of nearly 90 per cent. It is said that current used on electric automobiles will cost 20 cents a kilowatt-hour if derived from the storage battery carried by the vehicle and in most cases even more by the time it reaches the motor brushes. On this basis and figuring a saving of 10 per cent. in current for ball bearings, a commercial vehicle that runs five hours a day for 300 days a year will save current enough, if these bearings are fitted to a six horsepower motor armature only, to save about $150 a year of current costs. This does not consider the saving made possible at bearing points of running gear or power transmission system.

Ball Bearing Motors Have Other Advantages.

Ball bearings have other important advantages when used in electric motors besides current saving. In the first place maintenance costs are reduced because they do not need constant lubrication or adjustment. As there is no perceptible wear in such bearings, the armature will not run down on the pole pieces, as is possible when plain bearings deteriorate. Good com-

mutation is insured because of steady armature running and as bearings do not depreciate the air gap or space between armature and field magnets remains constant. As ball bearings occupy but little space, a motor of 25 per cent. more power can be designed with no greater overall length than a plain bearing type of less capacity.

Ball Bearings for Worm Drive.

An interesting application of ball bearings to a drive gear assembly of the worm type is depicted at Fig. 3. The motor casing is attached directly to the axle as the drive is by a worm carried by an extension of the armature shaft. In this case not only the armature of the motor is mounted on ball bearings, but the drive gearing as well. As considerable end thrust is present with a worm drive, the double-row bearing is especially well adapted for worm shaft support. It is housed in such a manner that it is capable of resisting end thrust present either on forward or reverse drive and carry its share of the radial load as well. The single-row bearing at the motor end of the worm shaft is mounted with a floating outer race and takes radial stresses only. This construction permits the worm shaft to expand if heated without stressing the bearings.

A longitudinal sectional view through the axle assembly to which this worm drive is applied is clearly outlined at Fig. 4. The worm gear is attached to the differential assembly, and the entire gear group is supported by a one-piece gear carrier integral with electric motor case as shown at Fig. 3. The axle is a full floating type, the wheels being mounted on the axle housing tubes and the shafts are used only for driving the wheels. The method of supporting the differential assembly in the carrier by two double-row bearings offers advantages of moment. One of the essentials bearing on worm gear drive efficiency is accurate centring of the worm and gear with which it meshes. This can be done very accurately by the bearing position adjustment nuts, which make it possible to locate the differential assembly so the centre line of worm wheel will coincide or register with that of worm shaft. This insures correct worm contact and the elimination of heat and wear. The double-row bearings can take all thrust on differential case with minimum friction.

The wheel mounting is typical of modern practise. The inner bearing of the double-row form takes all wheel end thrust, but is assisted in resisting the radial loads by the single-row bearing. Both bearings are mounted on the drive shaft housing tube and the floating drive shafts or differential assembly may be removed without disturbing wheels or alignment of gearing.

When an electric motor is employed as a source of power it is necessary to use a low ratio of drive between motor armature shaft and road wheels because of the great difference in the speed of armature and traction members. This is usually accomplished by compound gearing of some sort. A double reduction rear axle of the full floating type showing the application of ball bearings throughout is outlined at Fig. 5. The drive from motor is to bevel pinion, which turns a bevel gear on the countershaft. Attached to this countershaft is a spur pinion that imparts motion to a large spur gear on the differential case assembly. Two reductions of speed are thus provided between motor and wheels.

A Ball Bearing Double Reduction Drive Axle Design.

As will be evident, an axle of this type would be very inefficient if parts were mounted on power consuming journals because 10 bearings are required in this assembly and unavoidable gear losses are high enough without adding bearing friction losses. All thrust on the bevel pinion drive shaft is taken by a double-row bearing at the front end, while the major radial load is sustained by the large single-row bearing immediately back of the bevel drive pinion. The countershaft revolves in two double-row bearings, so arranged that position of bevel gear may be accurately gauged relative to bevel drive pinion. The differential assembly is also supported on double-row bearings. The wheel, a full floating type, is supported by a combination single and double-row bearing mounting as previously described.

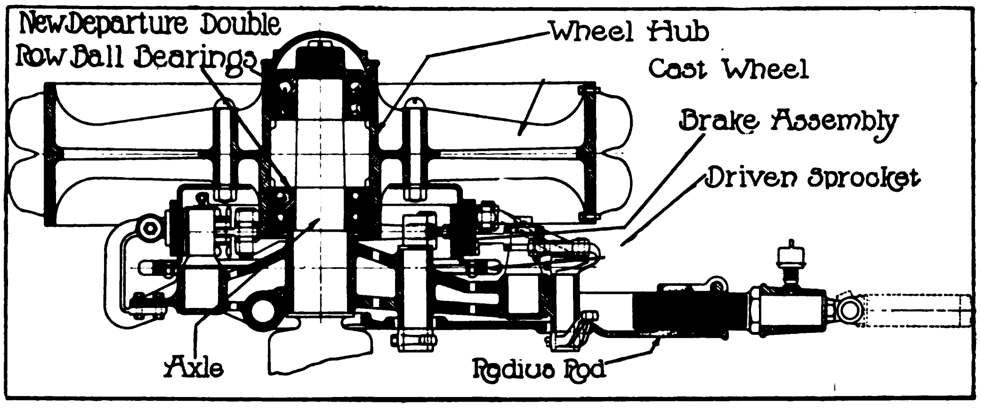

Fig. 7—Wheel End of Rear Axle of Heavy Electric Vehicle Showing Method of Mounting Wheel on Ball Bearings Supported by Stationary Axle Spindle.

Ball Bearings for Heavy Vehicle Wheels.

The front wheels of an electric vehicle are subjected to considerable end thrust when turning corners, as well as carrying a portion of the vehicle weight. The front hub assembly depicted at Fig. 6 is a typical construction suited for a heavy electric vehicle. The wheel, which is a steel casting, revolves on two large double row bearings mounted in such a way that each is called upon to resist end thrust and radial loads as well.

A rear wheel such as employed on the heavier commercial vehicles using axles of the "dead" or non-revolving type is clearly outlined at Fig. 7. The various parts are clearly shown and the method of mounting is practically the same as for the front wheel at Fig.

6, so further description is unnecessary. The important advantage the double-row bearing principle of construction offers where large loads are to be supported with bearings of comparatively small diameter is clearly outlined in these wheel mountings. If single-row bearings were used, the hub would be 33.3 per cent. larger in diameter to house bearings of sufficient radial capacity, yet these would not have the thrust capacity the lesser diameter double-row forms have.

The loads to be sustained by wheel bearings are high and they are subjected to considerable shock and vibration, especially in commercial vehicles fitted with solid rubber tires. If ball bearings will answer successfully the requirements of this service, it is apparent that their adaptability for all other parts of the car, where the loads are less severe, must be admitted. If they are used at points where the stresses are high, in order to reduce friction to a minimum, there can be no question of their endurance and saving in power where loads are lower. In view of the foregoing it is not difficult to understand why the best engineers favor ball bearings for electric vehicle service, and why practically all high-grade cars, even those sold at moderate prices, utilize ball bearings at all points where maximum efficiency is desired.

The Bavier Lubricating System, Inc., has been organized by George H. Duck, former manager of the New York service department of the American Locomotive Company, and Charles H. Bavier, which will establish in New York City a plant for the production of a new lubricating system for motor vehicle engines.

J. F. Sheppard & Sons, ice dealer at East Braintree, Mass., has entirely motorized its transportation department with KisselKar wagons and trucks.

HOLLOW STEEL TRUCK WHEELS.

Sightly Appearance of This Form of Equipment on a Large Passenger Vehicle.

Those who have doubt as to the appearance of steel wheels when used with machines that are to be utilized for passenger transportation, and assume that such equipment is not as sightly as those constructed of wood, generally form such opinion without definite knowledge of fact. The design of the steel wheels produced by manufacturers is generally such that it is hardly probable that the casual observer would discern the difference, and it might be that with the paint and varnish covering the metal there would be no condition that would attract attention.

The purpose of the makers of steel wheels is generally to produce what will be conventional in appearance, have sufficient strength, lightness and endurance to justify their use, and aside from the fact that there are usually fewer spokes than when constructed of wood, there is no real difference when contrasted with wooden wheels. These wheels are built to the S. A. E. standard dimensions and may be utilized with any form of tire, either quick detachable or demountable, and have all the qualities of the wooden wheels fitted with steel rims.

Double-Decked Passenger Omnibus with the Fischer Electric Steel Wheels, Demonstrating the Sightly Appearance of the Equipment.

An idea of the appearance of the wheels in service may be gained from the accompanying illustration, which shows a double-deck omnibus fitted with the Fischer electric steel wheels, these having hollow spokes and rims, and it will be noted that these have six spokes for the forward wheels and eight for the rear, while the average wooden wheels would have 12 forward and 14 rear. The sole American agent for these wheels is Peter A. Frasse & Co., 417-421 Canal street, New York City.

The assets of the Grand Rapids Motor Truck Company, Grand Rapids, Mich., successor to the Decatur Truck Company, have been purchased by Frank T. Hulswit for $17,000 at a bankruptcy sale, of which $6500 was the equity of the receiver in bankruptcy.

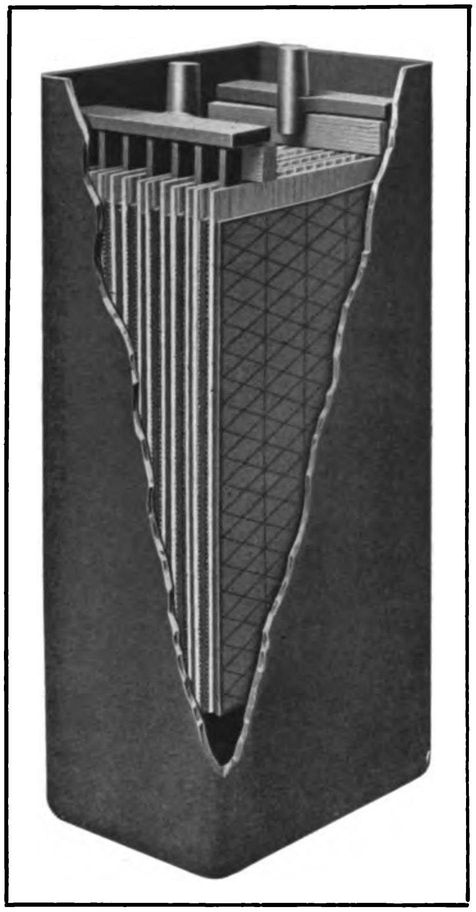
The S. G. Gay Company, Ottawa, Ill., has begun the manufacture of a 1500-pound gasoline delivery wagon, which will have the four-cylinder motor under a hood, and will be driven by chains. The vehicle will be known as the Gay wagon.

ELECTRIC VEHICLE PRACTISE.

Development of Cell Amperage by Use of Thin Plates, Increasing the Surface Area and Lessening Weight, With Better Construction Insuring Endurance---Examples of Wood and Rubber Separators, Straps, Terminals and Connectors.

By William W. Scott.

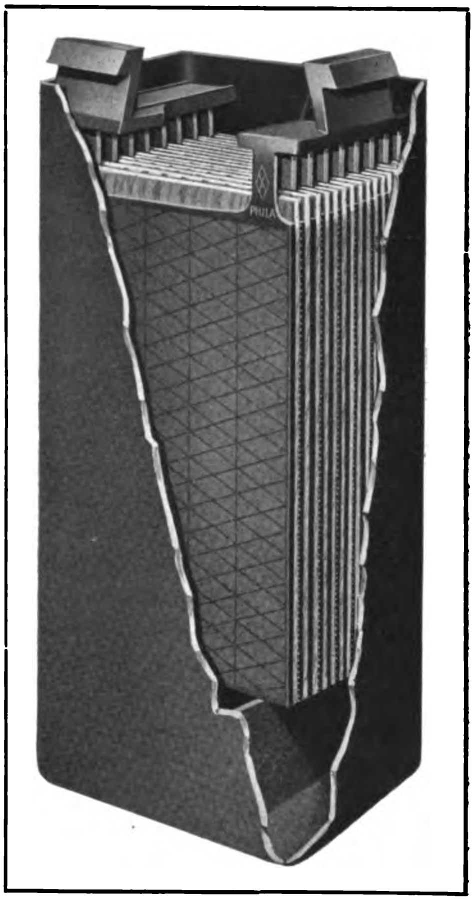
THE first plates produced were efficient so far as capacity was concerned, but the cells were heavy and it was apparent to battery engineers that it was essential to construct what would have less weight, so that in the last six years special attention has been directed toward producing what would have high efficiency and with as much reduction in weight as was possible. While it is not probable that the maximum has as yet been reached, a very large progression has been made by some manufacturers, comparison being made with earlier productions.



Philadelphia Thin Plate Cell, Assembled with Pillar Straps.

An example of this may be shown in the Philadelphia "thin plate" types, the development between 1906 and 1912 being in the use of thinner plates. The original W battery cell contained 11 plates and with a weight of 34 pounds to a cell had 140 ampere-hours capacity. The 13-plate cell weighed 33.75 pounds and had 168 ampere-hours capacity, this being an increase of 20 per cent. The 15-plate type weighed 33 pounds and had 189 ampere-hours capacity, an increase of 35 per cent., and the 17-plate cell weighs 32.5 pounds and has 204 ampere-hours capacity, an increase of 45.7 per cent. It will be understood that while the reduction of weight was comparatively small the plate area was much larger, and this really gave 64 ampere-hours because of the greater plate area exposed to the electrolyte. In this progression the main problem was the construction of the plate, so that, with its decreased thickness, it would have the strength to endure and afford efficiency under all requirements.

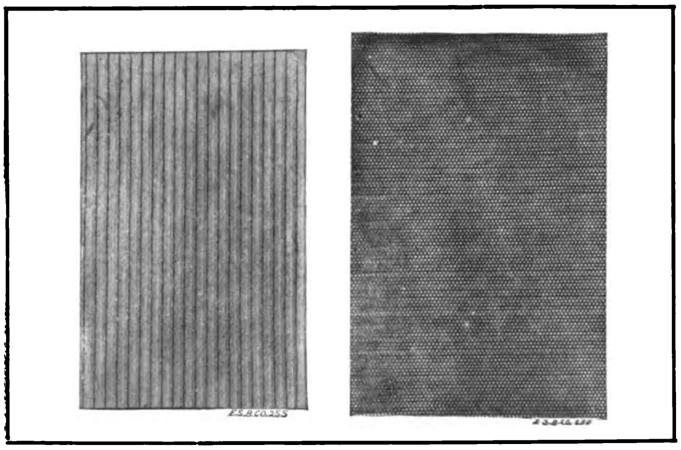
That is, the endeavor was to produce a thin plate that would endure practically as long as one of greater weight, and which would have the greater capacity because of the increased number used in a cell. Battery cell plates to be economical must have a definite life, and engineers have sought to construct what will have long endurance and the largest practical capacity. The cell that would not endure would be more expensive than that more enduring, its capacity would deteriorate in like ratio, and it would not be regarded as dependable, while the user would lose materially through withdrawals from service for attention, to say nothing of the lessened radius of movement of the vehicle through the reduction of capacity.



Philadelphia Cell Assembled with L-Straight Strap at Left and L-Plate Strap at Right.

Lead battery cells are widely used because they have been found to be commercially practicable with reference to cost, endurance and efficiency. The research work of chemists and engineers during the development period of the lead battery cell, which covers a period of more than half a century, has established that no couple that can be economically produced has the potential that is obtained with electrodes of sponge lead and lead peroxide and an electrolyte of dilute sulphuric acid. Innumerable tests and experiments have

been made in chemical constituents of acid battery cells, and to determine action and reaction, but no combination of metals has been found that yields as



Typical Lead Cell Separators, Channelled Wood at Left and Perforated Rubber at Right.

great a potential. The alkali or nickel-iron battery has not been considered in the above statement.

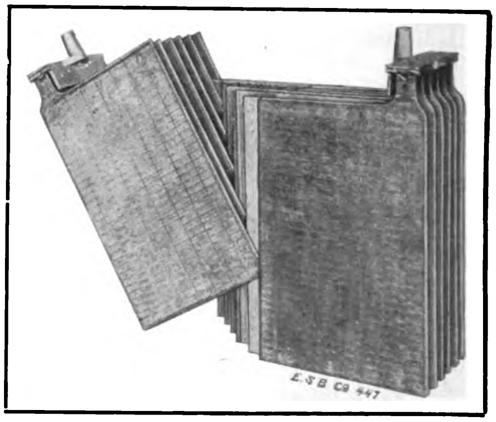
The electromotive force between electrodes of sponge lead and lead peroxide submerged in an electrolyte of sulphuric acid and water of approximately 1.225 specific gravity has been found to be about 1.94 volts, and with the increase of the specific gravity of the electrolyte the electromotive force is increased considerably, but there is no difference in this potential with the size of the cell. The voltage value of a cell can be rated at two or more, according to the state of the active material and the electrolyte. Voltage will vary with the temperature. For the purposes generally used the cell may be charged so that it will show a voltage of 2.5 or 2.55, and the cell when discharged to the degree regarded as safe will have a voltage of approximately 1.8, showing that the variance in potential is about .7 or .75 volt. These are the maximum and the minimum voltages that should be permitted.

The life of a cell is really based on cycles, that is. the number of complete charges and discharges it is given, and if the maximum results were to be obtained these cycles should be completed, and with regularity, for it will be remembered that sulphation or the formation of lead sulphate is a result of the electrolyte upon the lead plates. The minimum of discharge is fixed because there will be excessive formation of sulphate upon the plates, and as this sulphate is greater in volume than the lead or lead peroxide from which it is formed the surfaces of the plates will be insulated, the lead peroxide cracked or loosened and the material eventually dislodged, while the pores of the sponge lead plate will be filled with crystals of sulphion. In other words, the discharge of the cell below a voltage of 1.8 will cause sulphation that will only be dissipated with unusual care and attention, and may necessarily cause deterioration and deformation of the plates. Because of the possibilities of damage from careless use or neglect a plate must be sufficiently rigid to withstand the stresses, and as the thinner plate must be lighter it must also be better designed.

As the frame or grid metal cannot be changed much depends upon the design and construction, and as the active material must be retained in the grid the method of retention must be positive. Thus the thin plate must be developed with unusual care, and development can only be accomplished by lengthy experiment and careful observation. It will be noted in the case of the Philadelphia thin plate that the weight has been but little reduced, but the surface area exposed to the electrolyte has been decidedly increased. Sponge lead and lead peroxide have no high degree of conductivity, and as the thin plate is expected to have greater potency the frame must necessarily be so designed as to afford as thorough and even conductivity as possible.

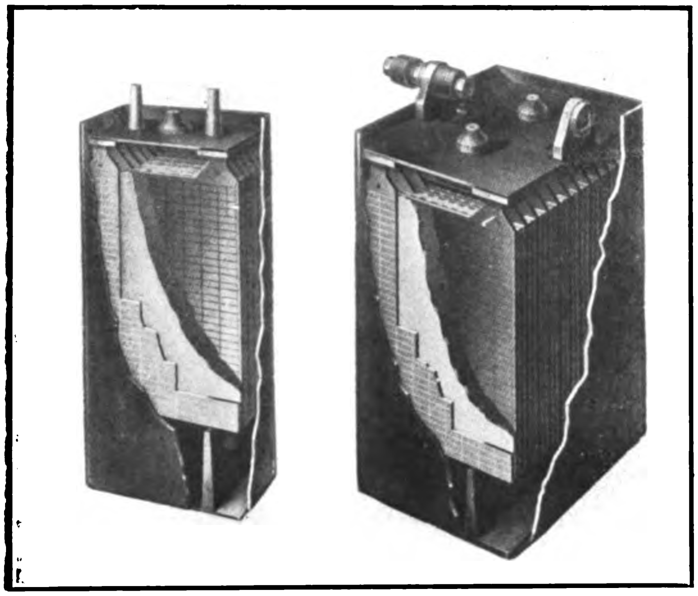
The influence of the electrolyte is greatest upon the positive plate. It will expand during the period of "formation" and during its service there will be more or less expansion and contraction of the lead peroxide, but the effects upon the negative plate are comparatively small, the changes not being of a character to materially affect it. There is, of course, necessity for securing good electrical contact between the plate frame and the active material, for otherwise there will be local action and reduced conductivity. Theoretically the action of the electrolyte upon the plate should be uniform, but this is not realized in practise, though the desire is to secure rapid diffusion of the electrolyte and the equalization of the concentration differences, for this is of great importance where cells are to be charged and discharged at high rates. The main objects to be obtained are capacity, freedom from excessive sulphation, the maintenance of potential during quick discharge, as well as endurance. In fact the general efficiency of the cell is absolutely dependent upon the quality of the plates.

Every battery cell manufacturer of importance in the industry has a department devoted to development. This is in charge of chemists and engineers, and the experiments are conducted with extreme care. For obvious reasons these departments work without publicity. No results are made public and nothing is permitted to reach a competitor, because there is the supposition, at least, that this would result in a direct loss, and a single determination may represent a large amount of money. In other words, whatever is accomplished scientifically is regarded as a trade secret,



Lead Cell Element with the Plates Practically Separated to Show Manner of Interleaving Them in Assembling.

and it is carefully guarded. Each manufacturer has his own processes and seeks to obtain whatever commercial advantage may be gained by their use. There



Sectional Views of U-S-L Battery Cell Construction: At Left, a Pleasure Vehicle Type and at Right a Design for Truck Propulsion.

are specific principles that are applied, but the use of these may lead investigation into what may seemingly be strange channels. But aside from the chemistry of battery cell construction, different tests are made, these to determine endurance, capacity, results during different conditions of charging and discharging, accelerating, and varying factors that are essential or incidental to the development.

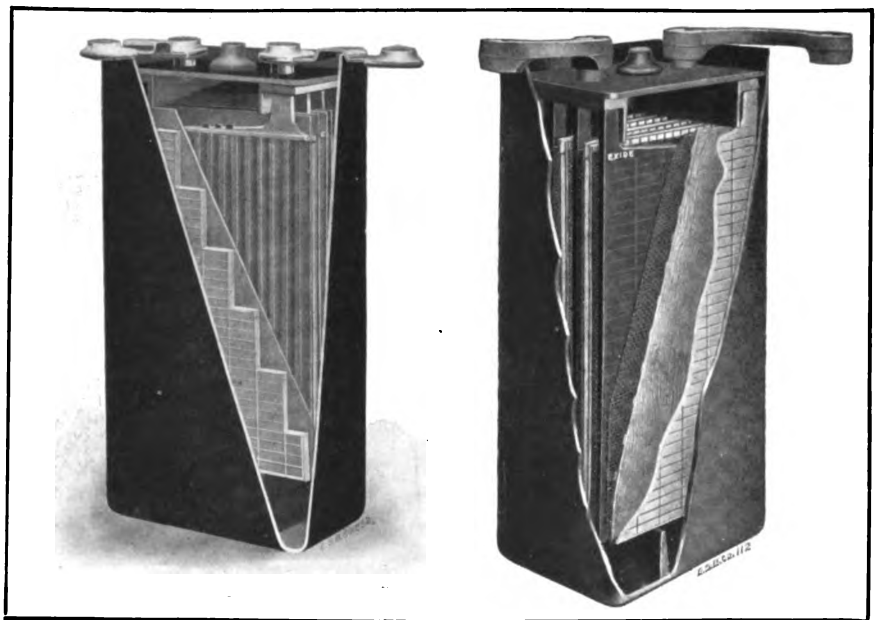
With reference to known active material and electrolytes it may be said that it is possible to determine the theoretical weight of either that would be required to produce a desired result, but these will vary in practise because it is impossible to obtain the porosity of the plates or the degree of penetration of the electrolyte. There is a gain in weight of approximately 15.5 per cent. in the conversion of metallic lead to lead peroxide, and a corresponding reduction in the conversion of lead peroxide to lead. Generally speaking, from three to six times the weight of metal is required in the plate because of the impossibility of exposing all the metal to the electrolyte.

The volume of electrolyte for a cell is determined by the engineer according to formula, the factors being the ampere-hour discharge, the initial density of the electrolyte and the terminal density at the expiration of the discharge period, and it is practical to obtain definite data on the basis of the known chemical changes. The quantity that is placed in a cell is only what is necessary to insure a desired action, for an excess would accomplish no useful purpose and the added weight would be a disadvantage rather than an advantage, for one object in successful construction is to minimize weight.

In the making of a battery the basis is number of cells, each of which is normally rated at two volts and whatever amperage the size will justify. As each battery as ordinarily coupled is with the cells in series it will be understood that this means the battery has the amperage of any one cell, but the combined voltage of the group, and if a voltage of 110 were required this would necessitate the use of 44 cells, and the amperage would be a given output of any one cell at the eight-hour discharge rate.

Thus to accomplish a definite work the engineer takes whatever number of cell units may be required and with them grouped for convenient handling (if for vehicles) he couples them and the battery is ready for use.

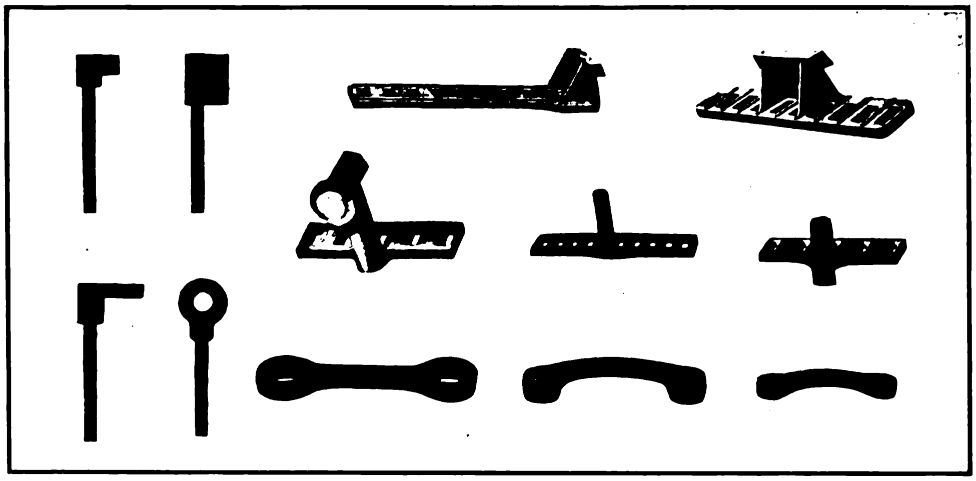
The plates for the cell, as has been shown, are made with an extension of the frame, which may be at the centre, at one end, or a neck formed at one side, which is of such length as may be necessary with the form of the jar. This neck or lug serves as a support for the plate when assembled, and it is composed of the same material as the frame. In the assembling of the element, as the series of positive and negative plates are known, all of the negative plates and all of the positive plates are coupled into separate groups. There is always one more negative than positive plates in a cell, for this permits the full value of the positive plates, and the coupling may be made by a bolt or rod, with collars to separate and preserve the relation of each plate, passing through a hole in the neck or lug; or the top of the lug may be placed in a hole in a strap or rod



Details of Construction of Exide Cells: At Left, Ironclad-Exide Cell with the Type of Connector Used with This Type; at Right, Cell Connected with Pillar Straps.

of metallic lead or composition of lead and antimony and connection made by tightening a nut; or the end of the lug and the strap may be fused to form a solid

metal connection. Whatever the method, the purpose is to form a perfectly dependable conductor of electric energy to the terminal, which is formed on the strap.



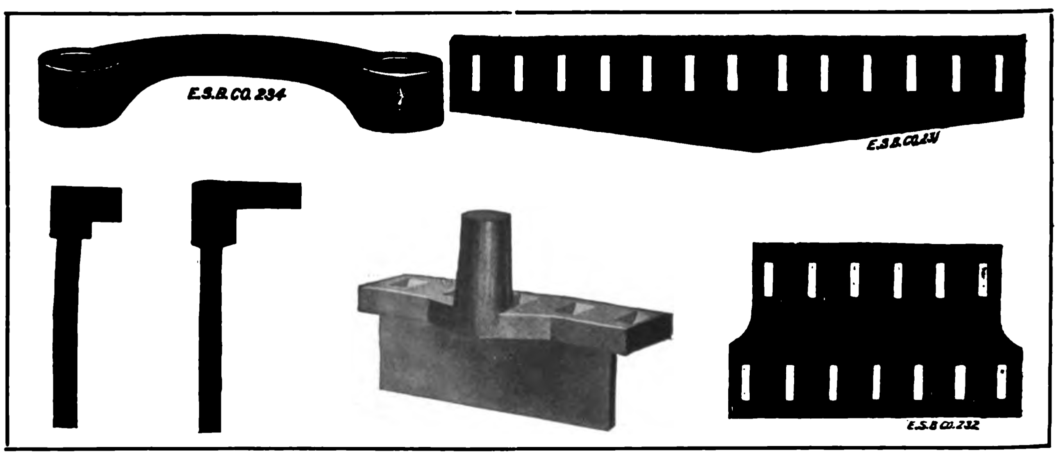
Straps, Connectors and Terminals: From Left to Right, Upper Row, Rear and L-Type Lead End Wire Terminals, L-Straight Strap and L-Plate Strap; Middle Row, S-Post Strap and Terminal, R-Post Strap and Pillar Strap; Lower Row, Front and R-Type Lead End Wire Terminals, S-Post Strap Connector, Pillar Post Connector and R-Post Strap Connector, Used with Philadelphia Cells.

The cell may be of hard rubber or vulcanite for electric vehicle use, but for other purposes it may be a glass jar, while for large cells it may be a wooden box or envelope lined with sheet lead. Considering the vehicle cell, the purpose is to have what will not be affected by the electrolyte and will be light in weight and sufficiently strong to endure under handling and to withstand the shocks that may result from driving. Usually hard rubber is found to give the best service, and the jars are made with a depth of several inches more than the length of the plates. The majority of the cells are made with several high ridges extending across the bottom, these affording a support for the element, and the space below is of such depth that the particles of active material separated from the positive plates will not accumulate sufficiently to reach the bottom of the element. In some of the cells the "bridges" are from two to three inches in height, and are generally several in number. These strengthen the jars and considerably improve their durability.

As the jars are to be enclosed in crates a rectangular form is chosen because of the better shape for packing, and because this the better economizes space, as well as affords the greatest capacity. The plates are generally of greater length than width, as may have been noted from the illustrations, and the difference between the two dimensions is at times considerable. The long and narrow plate may be considered the standard for electric vehicle use for several reasons. First, the floor area of the average battery box is small and cannot be increased without complications and limitations, and it is necessary that a definite number of cells be carried. This means that the base shall be small and the shape an oblong. The depth of the cell is approximately the length of the plate and the neck or lug, plus the space required for the bridges. Because of the necessity of limiting weight the walls of the cells are as thin as is practical, the thickness being dependent upon the use to be made and the general knowledge of the strength of the material.

It is apparent that to minimize weight the volume of electrolyte is kept to the lowest that is practical, a condition that is not essential with cells used for other forms of installations, and aside from having a sufficient quantity in the cell so that the loss through decomposition of the water will not have material effect no other condition is essential.

The cells are assembled by the manufacturer and in this work much care is taken to have the jars, the plates and the separators perfectly clean. The element is made up with the positive plates coupled by one connector, strap or bus bar, and the negative plates similarly connected. With the average assembly there is one more negative plate than positive, and between each positive and negative plate are two separators, which snugly fit and keep the plates in exact relation. The separators may be of different materials. In stationary cells glass or hard rubber rods are sometimes used, but in cells intended for vehicles the separators are generally of wood and rubber, or of rubber. There



Straps, Connectors and Terminals: From Left to Right, Upper Row, Pillar Strap Connector and Top of High Burned Straight Strap; Lower Row, Style D Terminal Connector, Style C Terminal Connector, Pillar Strap with Apron for Holding Down Separators, Top or High Burned Plate Strap, Used with Different Types of Exide Cells.

is an exception to this in the case of the "Ironclad-Exide" cell, in which the active material of the positive plate is contained in horizontally slotted rubber quills that are ribbed so that the ribs contact with the negative plates and maintain them at a precise relation.

The wood and rubber separators in sheet form are generally slightly longer and wider than the plates. The reason for the greater size is to prevent the "growth" of the plates extending across the space at top and in this manner causing a short circuit. Sometimes the top of the grid frame is sheathed with thin rubber, which is intended to allow expansion and contraction and at the same time prevent the possibility of "growth," this sheathing extending downward from the top member of the frame for a sufficient distance to insure against contact. As the element is assembled the separators are so placed that the tops project above the plates for perhaps .375 inch. Because the cell is practically closed and there is variance in the height of the electrolyte a corrosion of the plates is probable wherever exposed above the liquid, and this corrosion is prevented touching the plates by the separators.

The wood separators are about .140625 inch thick and of different materials, but often of basswood, which has a considerable degree of porosity. In these sheets are made on one side longitudinal channels about two-thirds as deep as the sheet and perhaps .125 inch wide, with the ribs formed by the channels about the same width as the grooves. Woods in their original state contain different elements in different proportions, some of them of acid nature, and were the woods used in this condition the resultant chemical action would be of serious consequences. The possibilities in this direction are of no special interest to the reader, but to the chemist are decidedly attractive. To eliminate these elements from the wood separators they are subjected to chemical treatments that neutralize or abstract them, so that when treated they have the cellulose structure and the strength of the wood and the electrolyte in which they are submerged for long periods is not in the least affected by them.

The channels in the separators are made both longitudinal and transverse with reference to the grain. One of the faults with the longitudinal channels is the probability of splitting, because the wood between the ribs is extremely thin and will not endure much handling, especially when dry. The channels transverse of the grain greatly reduce the danger of splitting and from the viewpoint of the battery engineer afford a stronger and better separator with the same weight. The function of the separator channel is to insure a circulation of the electrolyte between the plates. In assembling the smooth side of the separator is placed in contact with the negative plate.

The rubber separators used with wood separators are sheets of very thin hard rubber perforated with many minute holes through which the electrolyte contacts with the surface of the positive plate, and they are placed between the positive plates and the channelled sides of the wood separators. When all rubber separators are employed two are placed between each negative and positive plate. One of these is ribbed, as are the wooden separators, and the webs between the ribs are perforated with many small holes. The other is the thin perforated sheet.

The reason for the use of the thin rubber separator is to protect the positive plates against the disintegrating influence of the movement of the electrolyte against them, as well as to prevent the charring or carbonizing of the wood from the heat of the positive plate. With the element assembled the effect of the thin rubber separator is much the same as a cover or envelope and there is a sufficient contact of the electrolyte with the active material. Where rubber or glass rods are used these are placed at intervals between the plates and the electrolyte is allowed free access to the surface of the plates. As the active material is more or less porous the electrolyte saturates it, and it permeates the pores of the sponge lead, and there is sufficient influence to afford the rated capacity of the cell.

In battery manufacture the technical name of the neck of the plate is the plate lug, which is made thicker than the plate itself to insure strength to carry the weight and the better resist the corrosive influences of the electrolyte. Each group of plates is coupled in an element by a means of positive connection, and very generally by what are known as straps. The straps are cast from lead and are designed for different size cells, each having a series of taper holes, usually rectangular, into which the plate lugs are fitted. These straps are of different forms, some having aprons or webs that extend downward, being intended to maintain the relation of the separators; others are merely flat sections with the openings for the plate lugs, and again others have terminal posts or lugs, which are used with hard rubber rods and strips to hold down the separators. Because of the necessity of having absolutely certain conductivity and the possibility of loss at joints from imperfect contact, the general custom is to unite the plate lugs and the straps by fusing the metal at the joints, this process being known as "lead burning."

Where the straps are of the flat type the rubber "separator hold down" strips and rods are used, these being placed under the straps and over the tops of the separators, although in some cases these are kept in place by the cell cover. The cell cover is a sheet of hard rubber that is slotted to fit the lugs and aprons of the straps and when it is installed it is usually retained by a sealing compound, generally a composition of bituminous material, that is not affected by the electrolyte, and which is applied in a heated or plastic condition. This is removed by breaking or cutting when access to the element is desired. In the cover is a hole that is closed with a soft rubber plug in which is a small vent to liberate the gas. In this condition there is but little if any loss by slopping and through

this opening water can be placed in the cell as desired. By it also the electrolyte can be sampled by a hydrometer syringe, or by a hydrometer placed in the opening. Each cell is a complete unit and as many may be used as is required for any purpose, the number being limited only by the voltage that may be necessary or the space in which they may be grouped.

(To Be Continued.)

WILL ADVISE TIRE USERS.

Campaign of Education of Wagon and Truck Owners Begun by Manufacturers.

The Automobile Chamber of Commerce has adopted a resolution prepared by the commercial vehicle committee to the effect that a pamphlet on the cause of solid tire wear and destruction be prepared and published by the commercial vehicle department of the organization, and that manufacturers of wagons and trucks be requested to mail copies to all their customers, and that publicity be given through the daily and periodical press.

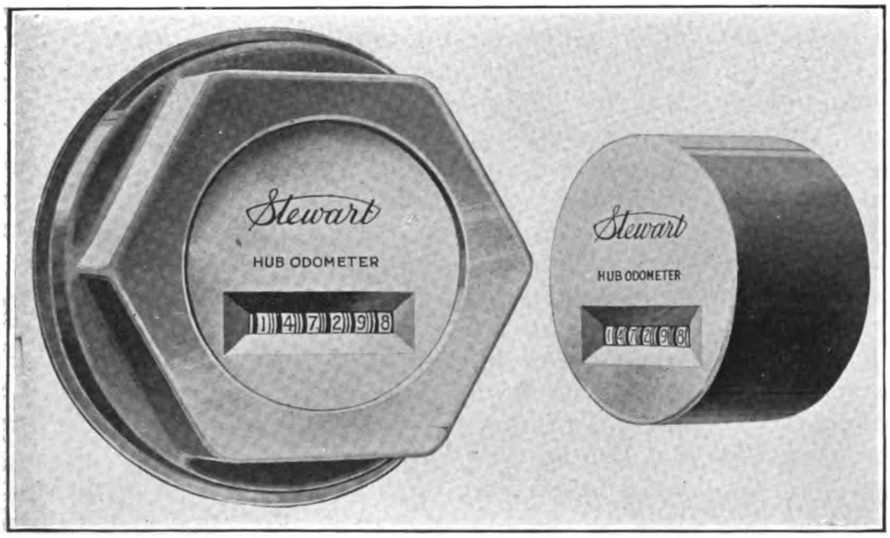
Advice has been sought from tire manufacturers, which will be included in the publication, but it was assumed that disinterested information from the truck builders would more influence the users than would statements made by tire makers, who are required to make replacements because of mileage guarantees. Emphasis is made to users that neglect of tires not only makes the first cost more than it would be did not the tire companies make good the damage resultant from abuse, that the burden of making replacements under the guarantee falls upon all users of tires alike, and that in preserving tires the user minimizes the wear upon the vehicle and lessens the repair expense.

The commercial vehicle committee has given the subject of tires study for a year, considering the effects of topography, paved streets, the effects of overloading and excessive speed, bad distribution of loads, sudden starting and stopping, inadequate tire equipment, diameter and contour of tires, the greater mileages obtained from solid tires in Europe, the human element to be dealt with and the probable result of offering bonuses to drivers. The belief is that by the adoption of different methods greater mileage can be obtained from tires and the cost of operation correspondingly reduced. The purpose of publishing the pamphlet is to reach the owners who may be or have been indifferent as to the operation of machines, and to correct ignorance or lack of knowledge of those in charge of or operating the vehicles.

STEWART HUB ODOMETER.

Speedometer Corporation Brings Out New Device for Recording Vehicle Movement.

The Stewart-Warner Speedometer Corporation, Chicago, Ill., has placed in the market a new hub odometer that may be utilized with any electric or gasoline vehicle, and it will record the movement of the vehicle accurately by tenths of miles up to a total of 100,000, when the register will return to zero and continue as before.



The New Stewart Hub Odometer for Either Gasoline or Electric Vehicles, Showing the Instrument in the Hub Cap and Removed.

This is the first instrument of the kind produced by this concern and with the knowledge of the requirements for service vehicles great care was taken in development. The odometer is enclosed in a substantial metal case that will fit inside the hub cap, and the end of the cap is cut away so as to expose the end of the odometer case and the register. When installed it requires no further attention.

It is operated by a positive drive that will not fail, steel pinions being used with worm and spiral gears. Each pinion is machined from steel and is heat treated and hardened to endure wear. By the use of an adaptation of the "Geneva stop" the registering dials are locked save at the instant of registering, and there is no possibility of a movement of the dials unless an indication is made. There are no springs or pawls in the instrument and when installed it may be regarded as thoroughly dependable. The dial is amply protected and with the miles shown by black numerals on white, and the fractions in red on white, the register can be easily read.

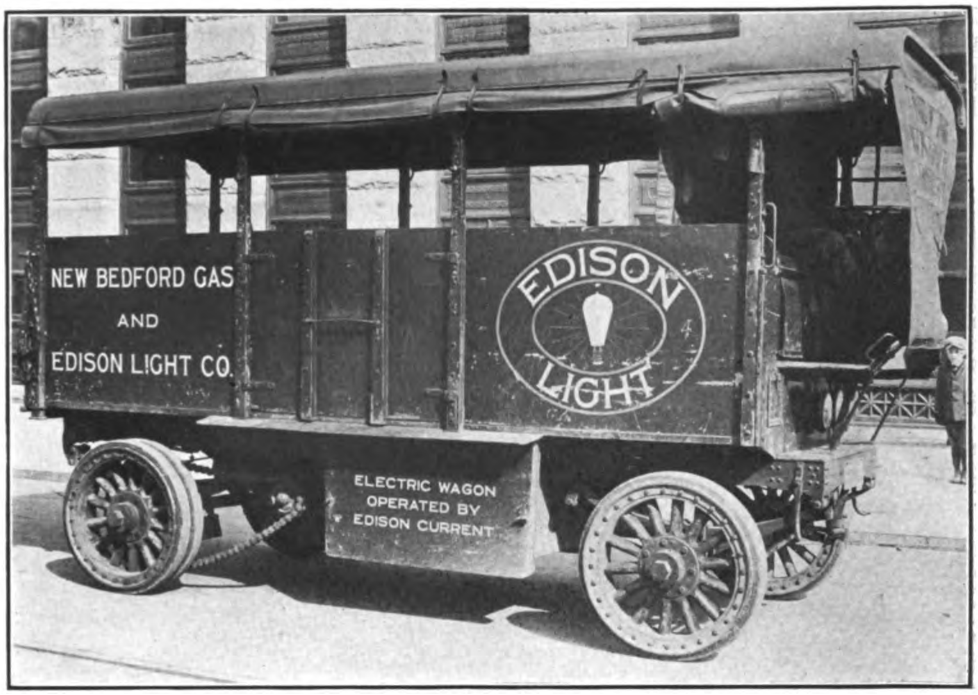
The Frank Parmalee Company, Chicago, Ill., which conducts a general baggage transfer service in that city, has purchased nine three-ton White trucks and will use them in its general transportation between hotels and residences and the railroad and steamship terminals. The company also uses a six-cylinder touring car in its work.

DEVELOPING POSSIBILITIES OF LOCAL FIELD.

New Bedford Gas & Edison Light Company Sets Example for Other Central Stations--- Some Results of Its Experimentation with Various Makes of Electrics.

CONCERNS engaged in the production of electric current are in a position to appreciate the value of studying the local field with a view to determining the possibilities for developing the use of electric trucks and wagons. A particularly interesting example is that of the New Bedford Gas & Edison Light Company, New Bedford, Mass. Having become convinced of the possibilities in that city, this concern has taken steps to place itself in a position to enjoy its full share of the business when it shall have been developed. The methods employed are such as to make an appeal to other central stations.

While the company has obtained information which leads it to believe that electric vehicles are much more economical in operation than horse drawn wagons, and for this reason is adopting them for its own use to a large extent, it is not prepared as yet to make public comparative figures. Its position is due in no small measure to the fact that even with its use of automobiles the business has grown so rapidly and the character of the service has changed to such an extent that it has found it necessary not only to keep all of its original horses, but to hire more teams outside than heretofore. Aside from the factor of economy, the company finds that the great advantage in the use of automobile equipment lies in the ability to accomplish the work more quickly, thus giving prompt service to its customers, a factor which it believes of sufficient importance to outweigh even that of economy.



The Giant of the Fleet; 3.5-Ton G. V. No. 4, Utilized in Hauling Coke, Etc.

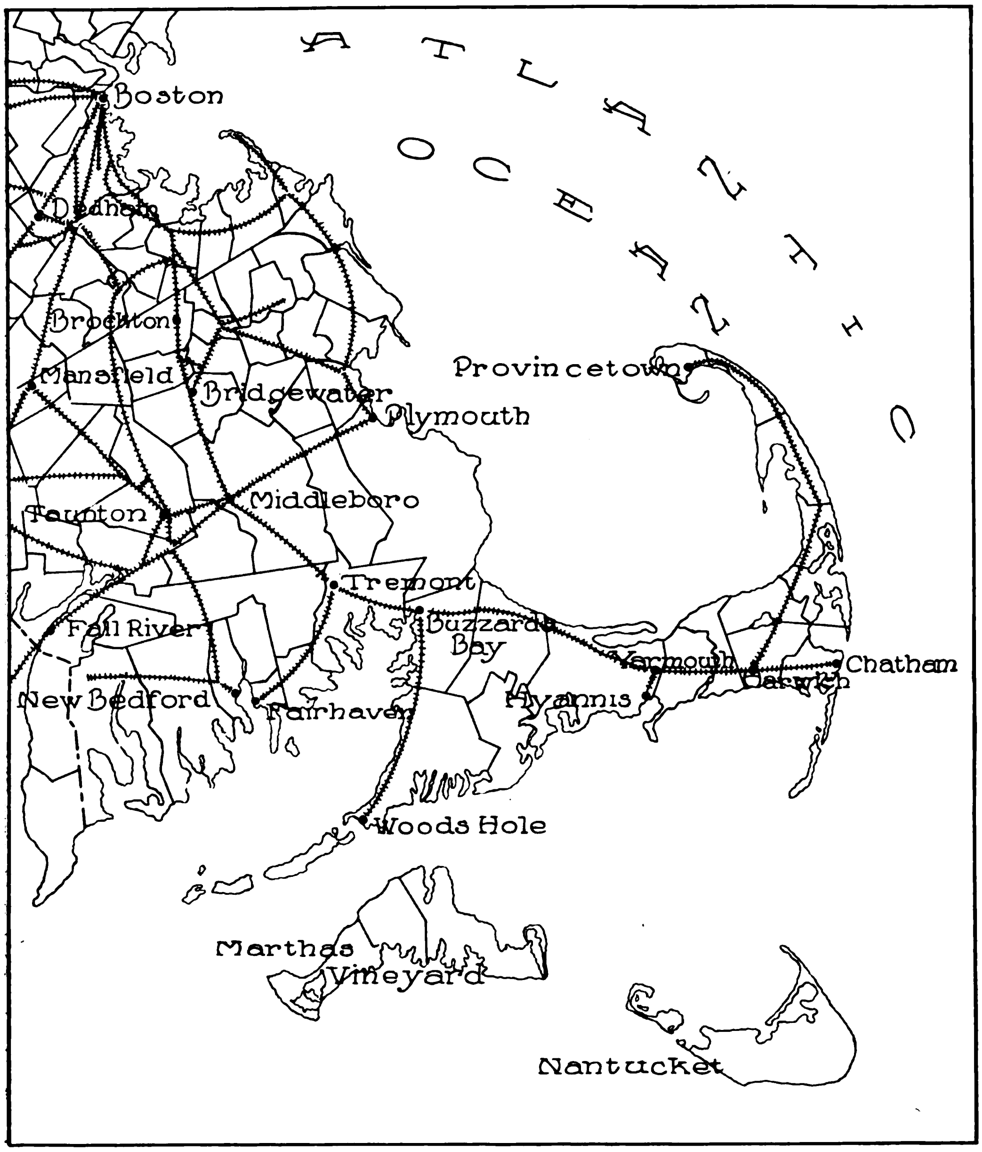
New Bedford is located on an arm of Buzzards bay, at the southern end of Bristol county, in southeastern Massachusetts, and about 56 miles from Boston. The Acushnet river separates it from Acushnet and Fairhaven on the east. It is bounded by the town of Dartmouth on the west, and on the north by Freetown. A little study of an accompanying map will suggest the limited area from which the city draws trade to itself. Fall River, with a population of 119,295 in 1910, is a near neighbor, only about 12 miles to the northwest, and is a formidable rival. Direct railroad communication between Boston and Cape Cod, with frequent service, tends to draw business that might otherwise be attracted to New Bedford, toward the Hub. The few small towns lying between this main line railroad and Bristol county have a certain choice between New Bedford and Boston. Out at sea, the Elizabeth islands, Martha's Vineyard and Nantucket offer a field of activity that is not neglected. Good boat service is maintained between these and the city proper, and on Martha's Vineyard, in particular, several well established motor 'bus and transfer lines insure prompt delivery of goods shipped thereto. The population of New Bedford, according to the 1910 census, was 96,652.

The city has an extreme length of about 10.7 miles and a width averaging 1.8 miles. The major portion of the residential district is located on top of a hill, the crest of which is about half a mile distant from the water front. This statement is general, and is for the purpose of indicating that the longer streets run in a northerly and southerly direction on top of the hill or along its sides. Those at right angles thereto do not present steep grades, and it is possible to cover a large portion of the city without encountering difficulty in this respect.

A map of the city, presented herewith, sets forth the arrangement of the streets, and the location of the principal factories, with which New Bedford is plentifully supplied. Aside from its whale fisheries, with an annual product valued at over $300,000, the city has some 65 cotton and yarn mills, operating over 2,500,000 spindles, or about 10 per cent. of the whole number in the United States. These mills use approximately

300,000 bales of cotton a year. There are a number of other industries, and the city is a large coal distributing centre, having steamship connections with New York City. Many sailing vessels also ship from this harbor.

It will be noted that New Bedford is somewhat distinctive in the arrangement of its business centre, so-called. In reality this is distributed at three points, as indicated on the map. The main centre is disposed about the streets leading up the hill from the water front, and, of course, those immediately adjacent thereto. Here are to be found the large wholesale houses and many of the department stores and retail establishments, hotels, etc. The business district to the north is quite as well defined as the so-called main centre, and somewhat the same may be said of that to the south, although neither of these is as important as what might be termed the central distributing point.



Map of Southeastern Massachusetts, Indicating Limited Area Served by New Bedford Business Men.

Most of the streets have excellent surface, macadam, bithulithic and asphalt being the materials generally utilized. A few of the older ways, down near the water front, are paved with cobbles, and some of them are in very poor condition. It is seldom necessary to traverse these, however, in making deliveries either from the wharves or the railroad freight station. The city government appreciates the value of good streets and every effort is made to extend the system as rapidly as possible.

Much of the raw material, aside from cotton and coal, is shipped to New Bedford by rail. Very few of the factories have their own sidings, over which the cotton and coal is loaded onto freight cars at the wharves and delivered directly at the door. Much of the coal is sent inland, and, of course, this is shipped by rail. These points are emphasized, because they have a direct bearing on the use of motor trucks and other conveyances.

The railroad freight station is on the water front level, about midway between the main business centre and that at the north, the distance between these two being a matter of 1.5 miles. The southern retail district is about a mile from the main centre. It is hardly practicable to define these limits with accuracy, since freight is deposited, either by rail or boat, at various points along the water front, extending from the railroad freight house at the north, down past the city wharves, and almost to the upper end of the southern retail district.

The wholesale and retail houses naturally are called upon to make deliveries in the section served by them. It has been pointed out that this section does not reach far inland, and, of course, the goods delivered on Martha's Vineyard and Nantucket are transported by boat. Occasionally, New Bedford concerns are called upon to make delivery on the other side of the bay, in Barnstable county. Once, at least, a Packard truck was sent around the bay, by way of Onset and Buzzards Bay to Falmouth, a distance of some 35 miles, with a load of lumber. This is a rare occurrence, however, and the main reason for this trip lay in the fact that less than a carload was required, making it possible for the New Bedford dealer to quote a price lower than what it would cost to purchase from a Boston house. Usually, New Bedford concerns are not called upon to make deliveries beyond a radius of 10 miles, although this is sometimes extended to 15.

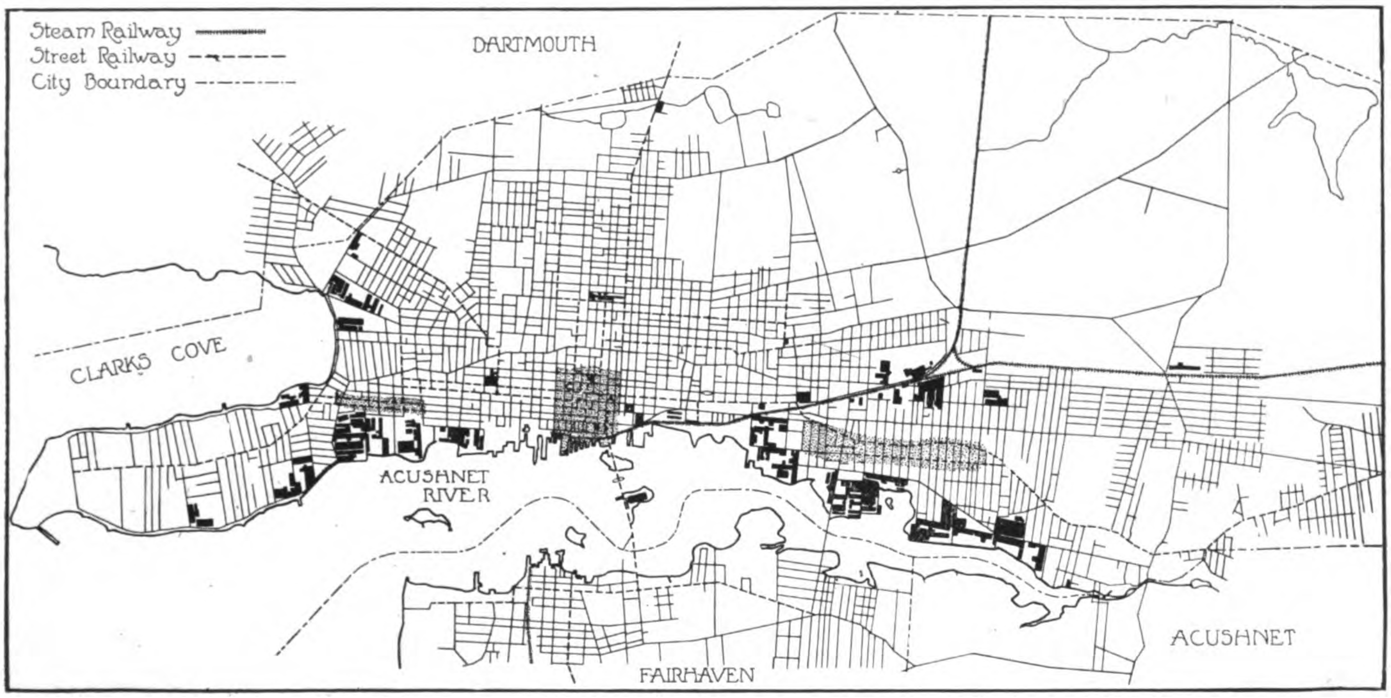
The Gas Meter Delivery Wagons; 1000-Pound Studebaker No. 2 and 1000-Pound Detroit No. 9.

These conditions have been described in some detail because of their important bearing upon the use of electric trucks and wagons. It was because of these conditions that the New Bedford Gas & Edison Light Company decided upon a promotive campaign. And while it was convinced of the possibilities, it determined to make such tests as should tend to prove its contentions and at the same time supply information of value in considering the final steps.

In October, 1909, the company purchased its first electric truck, a 2000-pound G. V., made by the General Vehicle Company, Long Island City, N. Y. This was followed in January, 1910, by a 1000-pound Studebaker, made by the Studebaker Corporation, South Bend, Ind. These two were continued in service until the spring of 1911, when two more G. V. machines, one of 1000 pounds capacity and the other of 7000, were added. In September, 1912, a 1000-pound Baker, made by the Baker Motor Vehicle Company, Cleveland, O., was purchased, and at the same time the company bought two electric runabouts, one a Baker and the other a Bailey, made by S. R. Bailey & Co., Amesbury, Mass. Two months later, in November, 1912, a 1000-pound Detroit, made by the Anderson Electric Car Company, Detroit, was added, and in December of that year a 4000-pound Baker.

It will be seen that the experiment, if such it may be termed, although in some respects the installation passed the experimental stage long ago, included a number of different makes, and machines of various carrying capacities. The results have been such as to afford the company some interesting and valuable data concerning the merits of the respective designs, a feature which may be turned to practical account when it is called upon later for advice regarding individual installations. It is hardly necessary to add that it does not care to make public its findings in this respect.

The ultimate object of the company is the maintenance of a service station for electric vehicles, both pleasure and commercial cars. Naturally, it expects to sell current, and it hopes, in addition, to provide that care and attention which shall insure the owner against failure or loss in any manner through the use of such vehicles. Plans are being prepared for this service station, which will be erected as an addition to the company's new office building at Purchase and Spring streets, in the heart of the city. These plans have not been sufficiently perfected to admit of dis-



Map of the City of New Bedford: Dotted Areas Indicate the Three Business Districts; New Bedford Gas & Edison Light Company's Present Office at A; Proposed New Building and Service Station at B; Present Garage for Electric Vehicles at C.

cussion, but the structure will be about 67 by 100 feet. Just how much space will be devoted to storage, charging, etc., it is impossible to state, since there is no means of knowing, at this time, how much demand there will be for work of this character.

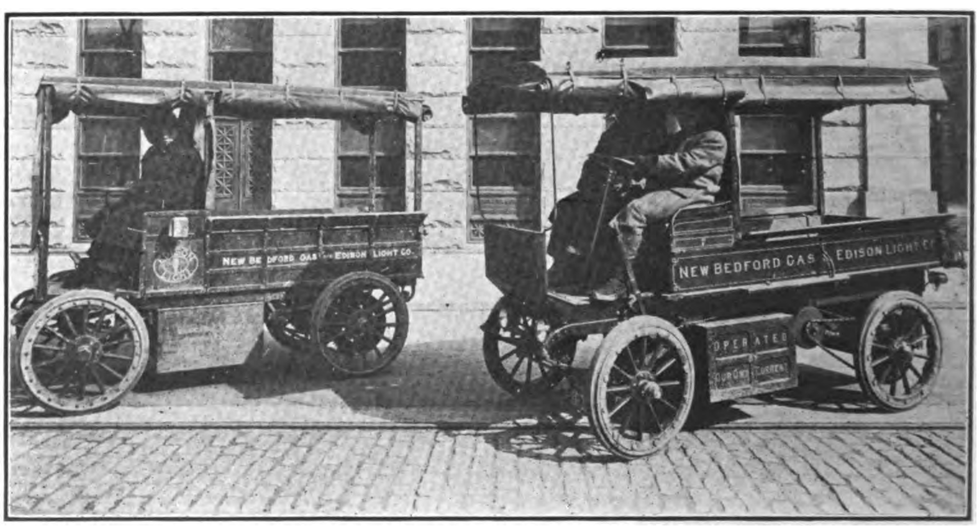
There are at present only two other electric wagons in use in New Bedford, these being of 750 and 1000 pounds capacity respectively, and something like a dozen electric pleasure cars. The building will not be ready for occupancy for some months, and it is hoped and expected that long before it is opened the number of such machines in service in New Bedford will be substantially increased. The campaign has reached the point where the company is prepared to offer facts and figures which it believes will carry conviction to the business man who is ready to consider the proposition. The company has no desire to take the agency for any make of machine, but it would welcome such agencies on the part of those already engaged in the automobile business in that city. It believes it is in a position to offer material aid to the dealer as well as the owner, and it is ready to talk business.

At present, the company's various departments are somewhat well distributed about the city. The main offices and salesrooms are on Middle street, near the corner of Purchase. Other offices are at the corner of Coffin and Water streets. The yards, shops, etc., are at the foot of Coffin street, on the water front. It is at this last named point that the trucks are garaged at present.

When the first machine was purchased it was placed in a wooden building adjoining the electric light station, at the foot of Coffin street. As the number increased, some of the space occupied by the horses was remodelled for this purpose. A shed was utilized, after it was reconstructed in a measure, for the charging panels, and one portion was reserved for a repair shop. This was only a small space in which work on the batteries might be done as occasion required.

The trucks and wagons are all known by number. The 2000-pound G. V. No. 1 is used in what is termed line construction work, this including the carrying of poles and wires, stringing wires, etc. The 1000-pound Studebaker No. 2 delivers gas meters and attends to the necessary work attendant upon setting these. The 1000-pound G. V. No. 3 delivers gas stoves and piping. The 3.5-ton G. V. No. 4 hauls coke and the large gas mains. The 1000-pound Baker No. 7 is used in the work of laying gas mains, carrying men, tools and small pipe. The 1000-pound Detroit No. 9 has the same service as that of the Studebaker No. 2—delivering gas meters, etc. The two-ton Baker No. 10 is another line men's truck, in service similar to that of the G. V. No. 1. The Baker runabout No. 6 is used as a foreman's wagon, and the Bailey roadster No. 8 as the electric superintendent's car.

Accurate account of the current consumed by these nine vehicles was kept for the six months ending June 30, 1913, with the results indicated in an accompanying table. These machines were charged every night, with the exception of No. 8, which was charged about every third night. No. 6 was given an occasional boost besides the regular charging. The voltage of the New Bedford current is 110, precluding the use of larger than a 42 or 44-cell battery. The average life of the batteries is placed at 15 months, although in some instances the experience of the company has been such as to indicate a little better than this.



The Half-Ton G. V. No. 3 Delivers Gas Stoves, While the 1000-Pound Baker No. 7 Helps to Lay Gas Mains.

TIRE COST A MILE FOR FOUR MACHINES.

Machine	Capacity pounds	Front	Rear	Cost a mile cents
G. V. No. 1	2000	36x4	36x4	2.56
Studebaker No. 2	1000	36x3	39x3½	1.65
G. V. No. 3	1000	36x3	36x3	1.50
G. V. No. 4	7000	36x6	36x5	5.08

The tabulation will prove of value to those who are considering the installation of electric vehicles, no matter where located, but, of course, the cost of current will be determined by the rate charged in any given locality. The experiment of this company has been with the added purpose of arriving at a decision with reference to this subject, and it has recently announced that it will be in a position to sell current for the charging of electric vehicles, providing current is not used between the hours of 4 and 8 in the afternoon, at the following rates: Up to 525 K.W.H., 3.5 cents a K.W.H.; 525-1225, three cents; 1225-2095, 2.5; 2095-4365, two; 4365-8730, 1.9.

In the matter of tires, the data thus far available with respect to the machines other than the first four are not held to cover sufficient time to be of value. Swinehart, Goodyear and Firestone tires are used, and the experience with the four machines cited has been such as to indicate a mileage cost as shown in an accompanying table.

Aside from the matter of tires and battery replacement, the expense for repairs has been very slight. Practically the only time lost has been due to the changing of tires. At first, it was impossible to secure provision for making such changes without sending the wheels to Boston. This work is now done at a local carriage factory. None of the trucks was out of service more than a day or so during the six months period mentioned above.

While the record of this installation is primarily of interest to the central station which is seeking an opportunity to develop this particular field, it will prove of decided value to the business man who is considering the advisability of making a change with reference to his transportation equipment. The results obtained, insofar as the company feels prepared to make them public, will serve as a basis upon which to compute the possibilities in any given locality.

RECORD OF INSTALLATION FOR SIX MONTHS, ENDING JUNE 30, 1913.

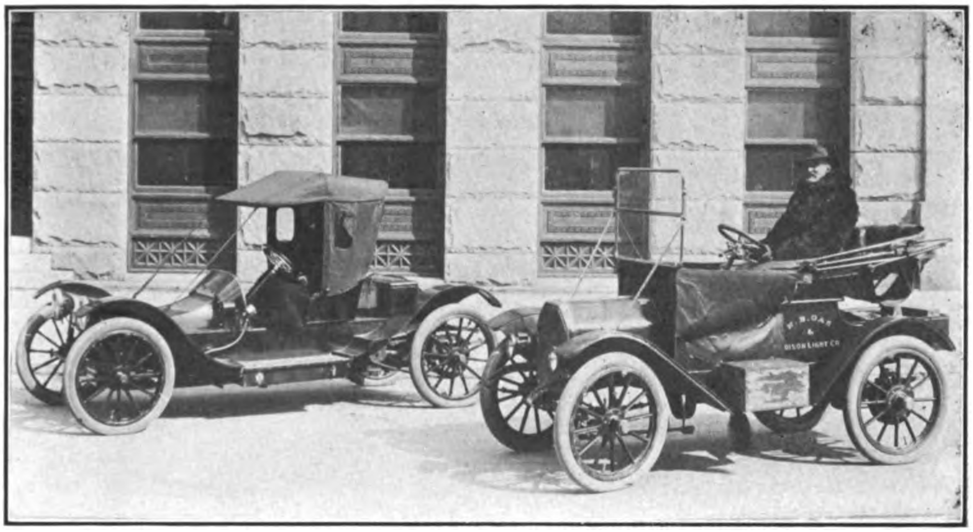
BOSCH EQUIPMENT IN TESTS.

Made Good Showing in Connection with Recent Fire Chief's Convention.

The Bosch Magneto Company is authority for the statement that at the exhibition of apparatus at the Grand Central Palace, New York City, during the recent international convention of fire chiefs, of 30 different gasoline equipments shown 29 were fitted with Bosch ignition systems. During the 12-hour pumping trials in which 11 engines competed, seven finished the tests, and all of these had Bosch ignition systems and five of them used Bosch spark plugs. The Ahrens-Fox pump, which was operated continuously for 12 hours and during that time exceeded its pumpage rating, was equipped with Bosch ignition system and spark plugs.



Electric Superintendent's Bailey Roadster No. 8 and Foreman's Baker Runabout No. 6.

SIX SIZES OF KISSELKAR TRUCKS.

Now Producing Machines Ranging in Capacity from 1500 to 12,000 Pounds.

The Kissel Motor Car Company, Hartford, Wis., and Milwaukee, Wis., is now turning out six sizes of service wagons and trucks, these being of 1500, 2000, 3000, 5000, 7000 and 12,000 pounds. These machines are built with four-ratio transmission gearset, with a purpose of insuring maximum work under all operating conditions. The material used in construction is in every sense high grade, and the proportions are generous for every working part, while these are heat treated and hardened, and ample provision is made for lubrication and protection against wear. For these machines the maker claims that they will afford exceptional endurance and service.

BEE MADE VICE PRESIDENT.

Sales Manager of the Edison Storage Battery Company Given Promotion.

William G. Bee, for a number of years general sales manager of the Edison Storage Battery Company, Orange, N. J., and for 11 years connected with that company, has been made vice president of the corporation, a recognition of his success in marketing the Edison battery cell. Mr. Bee is one of the most active men in the motor vehicle industry, is a director of the Electric Vehicle Association of America and is very widely known, his activities being among manufacturers, distributors and users of all types of mechanically propelled machines, but especially with the electric vehicle men.

William G. Bee, Vice President and Sales Manager of the Edison Storage Battery Company.

Mr. Bee was associated with Col. A. L. Pope when the Columbia Bicycle Company was manufacturing Columbia electric vehicles at Hartford, Conn., about 1897, and he was given leave of absence while he served as chief gunner's mate on the United States steamer Gloucester, which was J. Pierpont Morgan's yacht Corsair, converted for naval use, during the Spanish war. After the war he returned to the Pope Manufacturing Company and was associated with Col. Pope, having charge of the Pope exhibit at the Pan-American Exposition. He also represented the company in Mexico for a year. Meantime the Electric Vehicle Company had purchased the Pope interests for manufacturing electric vehicles at Hartford, but the Pope-Waverley Company built electrics at Indianapolis, Ind.

HAULED 15-TON BOILER.

Demonstration of Capacity of Knox-Martin Tractor in Transportation Parade.

During a recent parade of motor vehicles in Philadelphia, Penn., one of the features was a Knox-Martin tractor hauling a trailer on which was carried a boiler that weighed 15 tons, this being more than double the weight on any other vehicle in the procession. The tractor hauled its load with no evidence of capacity being reached, and seemingly could have drawn a considerably greater burden.

The value of this demonstration was twofold, the first being the possibilities for all kinds of work with tractor and trailer equipment, so that with a change of bodies that may be quickly made material of great weight or large bulk may be carried with equal speed, and, second, that there is a very large economy of street area, a factor that is very important where the highways are congested with traffic.

The use of horse teams in large numbers necessarily means slower work, and the cost increases rapidly. While one would not consider tractor equipment unless there were sufficient service to insure its operation a large part of the time, the possibilities for the varying requirements of those engaged in heavy haulage are such as to justify careful consideration. In such work as this that the cost of maintenance is very small when not in actual use is an important factor.

KELLY IS SALES DIRECTOR.

Baker Motor Vehicle Company Recognizes His Work in Developing Business.

George H. Kelly, for two years manager of the truck department of the Baker Motor Vehicle Company, was, at a meeting of the directors on July 9, elected secretary and sales director, this being in recognition of his success in developing the division of the business directly under his control. During his experience as executive of the truck department the company's trucks have been placed in practically every desirable section of the United States, as well as in some of the principal cities of Europe, Africa, Japan, South America and Alaska.

George H. Kelly, Sales Director, the Baker Motor Vehicle Company.

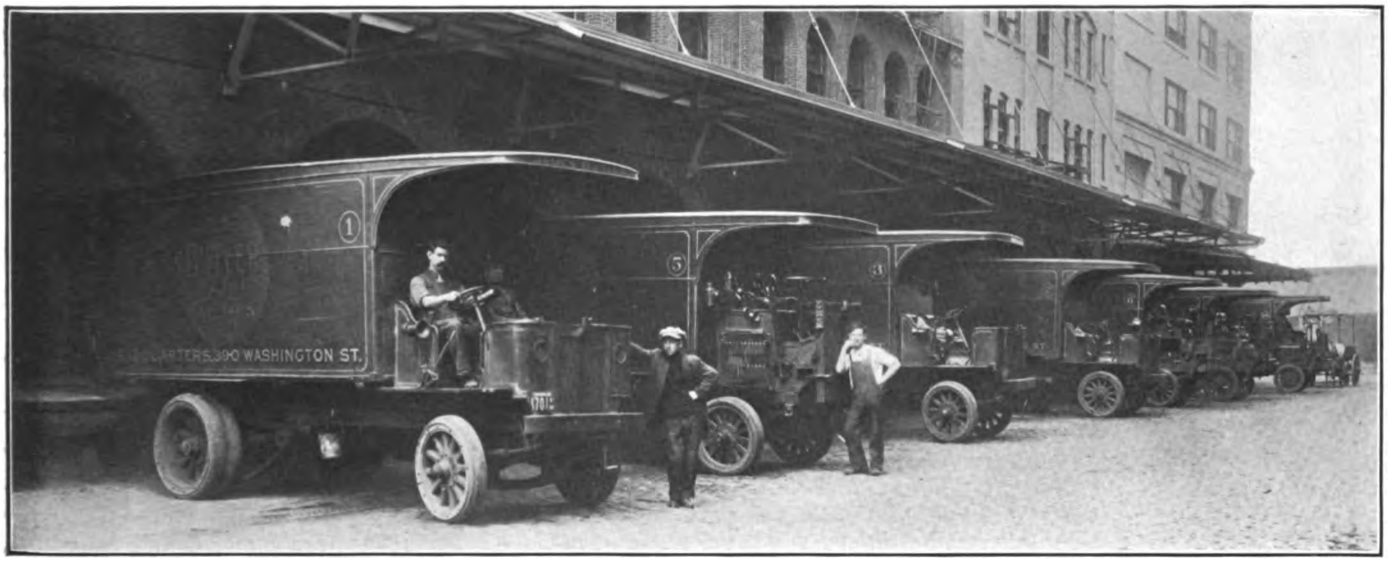
In the advancement of Mr. Kelly served as secretary were made in the personnel of other offices. R. C. Norton, who formerly served as secretary and treasurer, continues as treasurer of the company. E. J. Bartlett was made manager of the truck department and O. B. Henderson was continued as head of the pleasure car department. In making Mr. Kelly sales director the purpose of the company was to correlate the policies of the truck and pleasure car departments under one managing head, so that the co-operative work with dealers and customers might be brought closer together and be on a stronger basis.

TRUCKS CUT HAULAGE COST ONE HALF.

James Butler, Inc., Utilizes Machines in Stock Distribution to 250 Stores in Greater New York and Suburbs with Remarkable Economy from Common Sense Methods.

REDUCTION of haulage expense at least 50 per cent. by the use of motor trucks may appear to be an almost incredible statement, and that opinion would be justified in the mind of any man were it to be made by a person other than the business man who has realized this economy. Yet this has been the experience of James Butler, Inc., a business house that may be best described as "of New York and vicinity." The period covered by the use of motor vehicles is about five years, but during about half that time the work was done more or less experimentally.

James Butler, Inc., is probably the largest business of its kind in America that is concentrated in a comparatively small area. It maintains about 250 retail grocery stores in New York City and its suburbs, some being comparatively close to each other. Some are considerable distances apart. The precise location of these stores is probably known only to the office force and the shipping department of the warehouse, for were they all designated in advertising a considerable space would be necessary for addresses alone, and so the publicity usually specifies there are so many stores—Butler stores.



Line of G. M. C. Trucks at the Warehouse in Hubert Street, These Being All Five-Ton Machines and Used for the Distribution of Stock.

This business has been developed from a tiny corner grocery, and the Butler policy has been to deal direct with the people, the stores being located wherever the promise justified, and while many of these are of considerable size the purpose has been to have them within convenient distance and to develop what might be regarded as constant or family patronage rather than to expect custom from comparatively large distances. The number of stores has steadily increased, and when New York had been well provided for the suburbs were given attention. Now the resident of Long Island as far east as Huntington, the inhabitants of New Jersey as far as Orange, and the people of Westchester county in Yonkers, White Plains, Mount Vernon, New Rochelle, Mamaroneck and even Portchester, can find a Butler store close at hand.

In the early days of the Butler business the customers generally carried their purchases away. Delivery may have been discouraged, but as the stores began to multiply it was necessary to have the stocks replenished, which was done by buying from wholesalers who delivered to the stores. Later on a warehouse was established and buying was in considerable quantities, and from the warehouse the goods were distributed as required by the branches. It was easy enough to provide for the store delivery, for where one or two horses were required convenient stables made it possible to have horses and wagons in whatever number required. As a matter of fact the closer these were to the stores the better, but with the distribution of the supplies from the warehouse the problem was entirely different.

The main warehouse was located at Washington and Hubert streets, close to the railroad and shipping terminals, and from this the orders for stock were distributed by animals as far as they could be driven consistently, and beyond this the railroads were generally used. The number of stores has materially increased each year, but five years ago the business had reached such proportions that Mr. Butler decided that he would experiment with motor trucks, his first purchase being a Reliance three-ton machine.

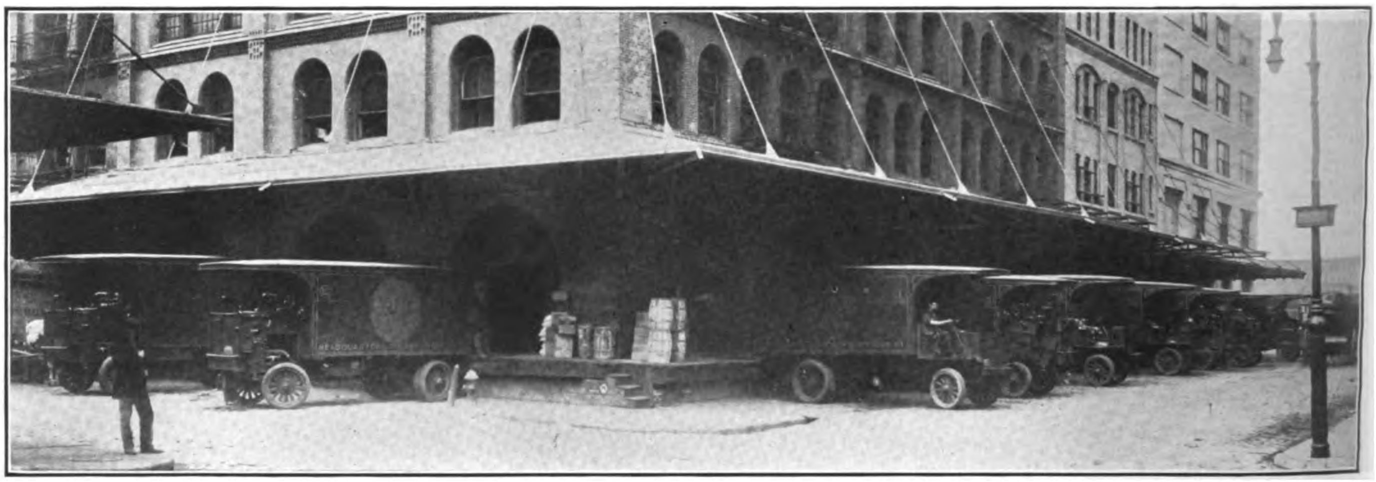
The theory of experiment was that the truck should be used for long hauls and the horses for shorter distances. If this use proved that the truck was econom-

ical for any specific work this could be studied. At that time the man who devoted his attention to haulage had but little information as compared with today. The work to be done was constant, to be sure, but it was always growing. The character of the business, however, was such that the accounting with reference to transportation was quite as definite as that of any other detail, and this experimental haulage was begun with the exact knowledge of cost of delivery and distribution. In this respect James Butler, Inc., was far in advance of the average firm, and it was this information, no doubt, that made possible the remarkable saving stated at the opening of this article.

It will be well for the moment to turn to the exact conditions with reference to haulage as they now exist. As may be assumed the volume of stock required for 250 or more stores is very large. The warehouse at Washington and Hubert streets is a big building. But this will house only supplies for a few days at most. Stock of all kinds is received daily at the different docks and railroad delivery stations, and it is transferred to the warehouse, but the warehouse was located with a view of minimizing this part of the haulage, and because it was central for distributing to all parts of New York and suburbs. With rare exceptions no stock is taken direct from the piers or terminals.

The different retail stores have one or more delivery wagons, but these are not considered in the traffic or distributing department. Each store is regarded as a separate establishment. It is under the direction of a manager who is responsible for its success, and the cost of delivery is kept in the accounting for each store. But the expense of distribution is charged against the business as a whole. In some instances the delivery wagons are kept at public stables; in others, stalls are hired in barns and the horses fed from supplies bought for the particular stores. Again, where the conditions will permit, there is a stable where a number of delivery wagons are grouped and the expense divided pro rata among the stores using the outfits. Some of these stables have as many as 20 horses in them, and wherever it is possible to group the delivery equipment of a half-dozen stores it is believed economical to do so. As the business now has in use something like 400 horses, the reader will understand that the delivery is a very large proposition, but each store manager handles his own service and economizes in whatever manner may appear desirable.

The main stable of James Butler, Inc., is now located at 222-228 West 68th street. This is a five-story brick structure, built for the purpose for which it is now used. The building is approximately five miles from the warehouse. Here were kept all of the horses and trucks used for distributing and a considerable number of the delivery wagons in the service of some of the retail stores. While the stable is a long distance from the warehouse, and theoretically it would have been best to have the stable for the distributing service close to the point where haulage is begun, that the delivery wagons of the retail stores could be provided for in large number was a fact that no doubt prompted the owner's decision to locate it where it is.



The Loading Platform at the Warehouse of James Butler, Inc., Washington and Hubert Streets, New York City, Extending the Entire Length of the Street Frontage.

At the time the first motor truck was bought the distribution to the stores was by two and four-horse teams and trucks. In addition to this all the stock received by freight by railroad or steamer was hauled to the warehouse by these same outfits. James Butler, Inc., bought high class horses and they were used humanely. While the hauls were long in many cases the animals were never overworked, and it may be said that for each pair of horses an extra animal was required to do the work. If a haul of unusual length were made the horses were given rest the next day; if used in hot weather or where the streets were obstructed by snow or where the footing was poor they were similarly relieved. That is, to secure constant service and to protect the investment in horses they were used with care and judgment. If the shipments were to be made to the distant suburban stores the stock was sent by freight wherever possible. It should not be understood that the horses were not used to their fullest capacity, but they were not abused.

When the truck was bought it was stored at the

stable in West 68th street. It was necessary to send it to the warehouse in the morning before beginning work for the day, but much of the time it could be driven into the stable without returning to the warehouse, so that there was comparatively little difference in mileage than were it kept near the central point for distribution. The experience with the truck justified the purchase of others, and these were Reliance machines. Later on a number of Garford wagons and trucks were bought, and still later a fleet of G. M. C. trucks was purchased. The motor equipment of the business is today 41 vehicles in all, of which 19 are G. M. C. five-ton trucks, five are Garford five-ton trucks, 10 are Garford one-ton wagons, one is a five-ton Reliance truck, and six are one-ton wagons, there being 25 five-ton trucks and 16 one-ton wagons.

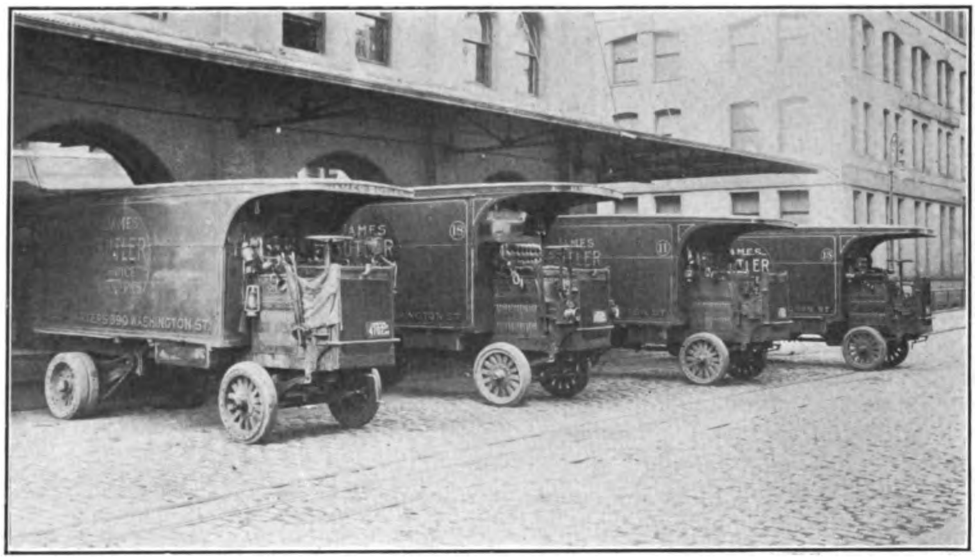
The five-story building in West 68th street is a combination stable and garage, the east section, divided from the stable by a heavy brick party wall, being used for the service station. The first floor is used for storing the machines, the second for storing the machines that are out of service for repairs, the third for storing machines that are ready for service after repairing, the fourth for an automobile repair shop, and the fifth for woodworking, painting and blacksmith shops. A large elevator carries the machines to the different floors.

The chassis only are bought and the bodies are built, painted and installed in the shops, for this is not only economical construction, but the bodies are constructed to designs that are found to best meet the requirements of the service. The repair shop is fully equipped with machine tools for doing all kinds of repair and reconstruction work, and there is every facility that five years' experience has shown to be necessary.

The five-ton trucks are used in distribution only, and the ton wagons are used for delivery from retail stores. The ton machines have been placed in service wherever the business appears to justify, and the results have been in every way satisfactory. The experience with the delivery vehicles does not warrant the assumption that eventually the entire store delivery equipment will be motorized, because it would seem hardly practical to handle motor wagons as horses are now handled with reference to storage and attention, though there is no doubt that a considerable number could be provided for in different garages convenient to the stores. It would not be possible, however, to have the care and maintenance under the direct supervision of the superintendent of the garage, which is undoubtedly a very large factor in the economical use of the machines that are now in service.

The regular distribution from the warehouse is made by 20 five-ton trucks. These are sent away from the garage at 6:15 each morning and the drivers report at the warehouse to the head of the traffic department, as the chief shipping clerk is known. Some of these machines are used solely for the haulage of fresh meats and others for groceries. The fresh meats are kept in cold storage at the warehouse and are cut to secure the qualities and weights best suited for the custom of the retail stores. The meat truck bodies are fitted with rear doors so that the contents are protected against dust and can be carried long distances without deterioration. Experience has shown that icing the meats, which was always necessary with horse vehicles, is unnecesary, and they can be delivered well chilled.

Loading platforms extend the full length of the warehouse in Washington and Hubert streets, and large doors give access to them. The orders from the



Group of G. M. C. Trucks, Showing the Types of Bodies Used for the Distribution of Groceries and Meats by James Butler, Inc.

store managers are received at the warehouse and are made up in piles on the main floor close to the doors. Each truck is sent out on a route determined by the head of the traffic department. The truck for a specified route has a regular station at the platform and on arrival it is backed to the station. Near this the goods for the stores are collected, each order separate. The orders are loaded on the trucks in reverse of the order of delivery, the driver and his helper doing the loading.

Each morning the 20 motor trucks and 10 two-horse trucks report to the warehouse at 7 or earlier. Generally the 10 horse trucks and half the motors are sent to different piers and railroad terminals, and as soon as these have been sent away the remaining 10 motor trucks, which are those having the longest routes, are stationed at the platform. As rapidly as possible these are loaded, this work requiring from an hour to an hour and a half, and while this is in progress the trucks sent for freight are arriving and unloading, the receiving necessitating the use of a great

deal of the platform. After the motor trucks have discharged the freights they are in turn loaded for the routes and sent away.

The average truck load is five tons, care being taken not to exceed the weight allowed, and as a rule the route will include from four to six stores, five being a fair average. As some trucks make two route trips a day this means that for them the number of stores to which delivery is made may be 10. Each store is given regular delivery of orders from the warehouse three times a week, so some machines will, or can, on the above basis, serve 20 stores, but this average is not maintained, for some routes are so long that but one trip is made a day, and in one instance but one delivery. With one or two exceptions all the stores are supplied by the trucks, and when there is time remaining after the distributing work the machines are utilized in hauling freight to the warehouse. As a rule the work is completed so that the trucks are back to the garage by 6 in the afternoon or thereabouts.

G. M. C. Truck at the Loading Platform in Hubert Street of the James Butler, Inc., Warehouse, Showing the Facilities for Quick Handling the Freight.

The 10 horse trucks are worked constantly on freight haulage, in many instances the hauls being very short; some for not more than three or four blocks, and where the greatest value of the motor truck is its speed it will be seen that their use would mean comparatively little gain in this work, and really a loss when the greater cost is considered. The longest freight hauls will rarely exceed a mile, and for these the motor trucks are used. In this part of the work they have a distinct value.

From the viewpoint of the traffic department of the business it is maintained that the 20 trucks used for distributing are at least the equal of 50 teams of horses, and this means two and four-horse outfits. Considering 10 four-horse and 40 two-horse teams this would mean that not less than 180 animals would be necessary to do this work, while there would not be by any means the same possibilities of suburban delivery. Previous to the use of trucks this delivery was made by freight, which necessitated haulage at either end, besides the expense of shipment.

There is another condition that is of considerable importance. At midnight during the season for fresh fruits and vegetables a buyer begins purchasing at the different piers and railroads, and several trucks follow him, collecting the purchases. These trucks are loaded and by 3 in the morning begin delivery trips, each covering a route. By 9 at the latest the trips are finished and the trucks return to the warehouse. In this manner it is possible to supply a very large number of the stores with the best stock procurable, but with horses only a small area could be covered and there would be more or less loss in hot weather. Throughout the year the stores are supplied with vegetables and fruit, and in extreme low temperatures no loss is experienced from freezing, so well are the loads protected and so quickly are the trips made.

So well is the organization administered that there is but little need of extra trips, for each store manager makes requisition and endeavors to make whatever replenishment is necessary before a stock is exhausted. Should there be need, however, the traffic department can make a special delivery, although the desire is to send out only fully loaded trucks. The longest run is to Huntington, L. I., and each day a truck carrying five tons makes a single trip, this store being about 40 miles from the warehouse. Adding the distance from the garage to the warehouse the mileage of this machine is close to 95. From the standpoint of the business it is more profitable to operate the truck for this work than to pay railroad freight. The average mileage of the trucks is approximately 40. This is about the distance covered by the delivery wagons. The drivers return to the garage between 3 and 7 in the evening, the fruit and vegetable trucks coming in first, and those on the regular routes from 5 on.

As each machine is driven into the garage it is seen by the foreman or the superintendent. Either of these men who may be on duty notes the truck or wagon as it is driven in. The first duty of the driver is to report the number of the machine, the time in hours and minutes it was out of the garage, the quantity of gasoline consumed in gallons, the oil used in quarts and the kerosene used in pints, the grease used in pounds, and the condition of the vehicle. These entries are made in a large loose leaf book by a clerk, and in ink. In this record is also entered the time the truck was in the garage, thus accounting for the entire 24 hours.

The night foreman examines this book and from it assigns men to do whatever work may be necessary. Should a condition be found that requires more work

than can be accomplished in a night the machine is withdrawn until it can be repaired. A stock of parts of all kinds is available, and with the repair facilities and men on duty nights a work of considerable proportions can be undertaken. Overhauling is done during the day and by a separate force of men than that engaged in repairing.

Assuming the case of the truck brought in in good condition: After the report has been made it is greased and oiled, the fuel, gas and water tanks filled, and it is washed. Whatever work of this character is done is shown in the time sheet of the men working on it. Thus there is a charge for labor and for supplies against this machine. If an adjustment is necessary the labor for this is charged. Should a repair be made the labor and the cost of the part or material is similarly recorded. The tires are examined and should there be need of attention or change the work is accounted for in the time sheet and the statement of material supplied.

The wheels of the truck are designated by position on the machine and by the number of the vehicle. The tire record shows the maker's serial number, the size, the position, the date installed, and the date of removal, and in addition the mileage driven. In the event of a tire change in the garage the labor is charged and the new tire entered, but if a wheel is damaged on the road a new wheel is put on, this being a distinct saving in time, and the wheel record will show this fact, for no further change is made, the wheel and tire being used until there is need of further replacement. It will be seen that the wheel record may vary somewhat from the actual mileage of the machine.

There is an emergency wagon kept at the garage in which are hand tools of all kinds, and in the case of accident whatever may be necessary in the way of parts is placed in the wagon and it is sent away. Should the repair be of such character that it can be handled on the road it is done by the mechanic in charge of the emergency wagon, but if it is a shop job a notification is sent to the driver of the nearest truck, who can always be reached by telephone in a short time, and he reports to the disabled machine, removes the load remaining and distributes it. The mechanic and the crew of the damaged vehicle do whatever work is necessary to return it to the garage.

Each truck is overhauled annually, and in rotation, sufficient time being taken to place it in first class condition, and while the mechanical work is progressing the body is given similar attention and painted. There is generally one machine under overhauling orders in the shop at all times. Each overhauled machine is thoroughly tested before delivery to the traffic department for use.

When trucks were first purchased drivers of experience with machines were hired, but the experience was that these men did nothing else than drive, and were not inclined to do more handling of the load than was possible. Not only this, they wanted to drive at maximum speed and had little sense of responsibility. Then the method of administration was changed. Men were trained as drivers and were not trusted with trucks until the superintendent was confident of their competency. They were first employed as helpers and after being taught to drive were allowed to drive with different men who made report on their ability. One man finally decided whether or not they were capable. If a man promised to become competent with more training he was allowed to obtain more experience, the policy of the superintendent being to get good men and to help them in every way if found worthy.

Each driver who is placed in charge of a truck or wagon is first credited with the machine. An exact record is made of its condition. Each day against this vehicle the cost of gasoline, oil, kerosene, grease, washing, cleaning, adjusting, repairing, labor or material of any kind, is charged, and in addition tires as installed or repaired, wages, and the pro rata of the overhead, which includes insurance, rent, depreciation, lighting, heating, water and the necessary clerical work. From this record it is possible to ascertain the precise expense of operation, maintenance, attention and investment, by the day, week, month or year, or for the period that any man may be in charge. The driver is responsible for so much property and for its economical use. Upon his ability to use the machine economically depends the wage he receives. The man who can do his work at the least expense is regarded as the better man, no other factor being considered. The men are paid according to the showing that is made in the financial account of the machine. Excellent wages are earned by these men and they are assured of employment so long as they can keep their trucks up to the standard and within the expense limit, but those who can show the lowest cost have the greatest earning capacity. This policy is to make each driver manager of his truck, just as the stores are managed, and to expect him to make the greatest profit that is possible with it, although there is, naturally, a limit to what can be accomplished. The men are given encouragement to do their best, and there is a great deal of rivalry between them as to who will do the best work. The policy has not brought about neglect of conditions that might cause deterioration through the desire to do work as long as possible without attention, for the system of inspection insures against this, and the men realize that in the end, through repairs or overhauling, they would fare badly.

The economy of 50 per cent. or more in the store distribution expense is not an estimate. When horses were used exclusively the accounting was absolutely accurate, and much attention was given to handling the freight with least expense. The loading platform at the warehouse was built to economize delivery and dispatch stock, and there has been no need of change since motor trucks were installed. The saving had been made through the superior capacity, speed and larger radius of movement of the machines, and the system that places the responsibility upon the drivers.

MINIMIZING BEARING FRICTION.

By W. H. Stillwell, M. E.

THE electrically propelled vehicle is probably the best example of concentrated design that is in general use today. Due to the fact that all of the power must be obtained from a storage battery of limited capacity, the distance travelled depends not only upon the amount of power available, but upon the percentage of this amount that can be converted into tractive effort. The elimination of all unnecessary weight in the car and the reduction of friction and electrical losses are about the only ways of increasing the mileage for a given battery and motor power.

The use of alloy steels and light weight bodies has reduced the car weight almost to the limit. Since there seems to be no good way of reducing the weight of battery and motor, and no way of reducing the electrical losses, most of the manufacturers have turned their attention to the reduction of friction losses. The shaft drive car has helped a great deal, and a few are now changing to worm drive to obtain a further reduction.

Needless to say, the bearing friction is the most important of all of the mechanical losses and the highest type of anti-friction bearing is required. The annular ball bearing has been universally adopted on account of its having the lowest friction coefficient of any type now on the market. There is of course a vast difference in ball bearings, and their anti-friction qualities. The high polish of balls and raceways and the accurate assembly of the bearing are the two main features, although the separator friction and the energy required to revolve the separator with the balls also has quite an appreciable effect. Any bearing having uniformly hardened steel, highly polished, uniformly hardened balls accurate to .0001 inch, highly polished raceways of a radius equal to approximately .6 of the ball diameter, and a light weight separator touching the balls at one point only should give a minimum friction loss.

Annular ball bearings now on the market also vary considerably in their load capacity. Primarily, of course, this factor is determined by the elastic limit, and the method of hardening the steel. Assuming that these qualities, and the accuracy of assembling are equal, the load capacity will then only vary with the form of raceway and the number and diameter of balls in the bearing. The load capacity and the friction loss of a given ball is greatest when the diameter of raceway is equal to the ball diameter. The load capacity and friction loss is smallest when the raceway is a plane tangent to the ball; since a minimum of friction with a maximum of load capacity is required, a compromise between these limits is necessary. Many experiments have determined a correct radius of curvature which is approximately .6 of the ball diameter, and this figure has been adopted by all of the leading manufacturers as standard.

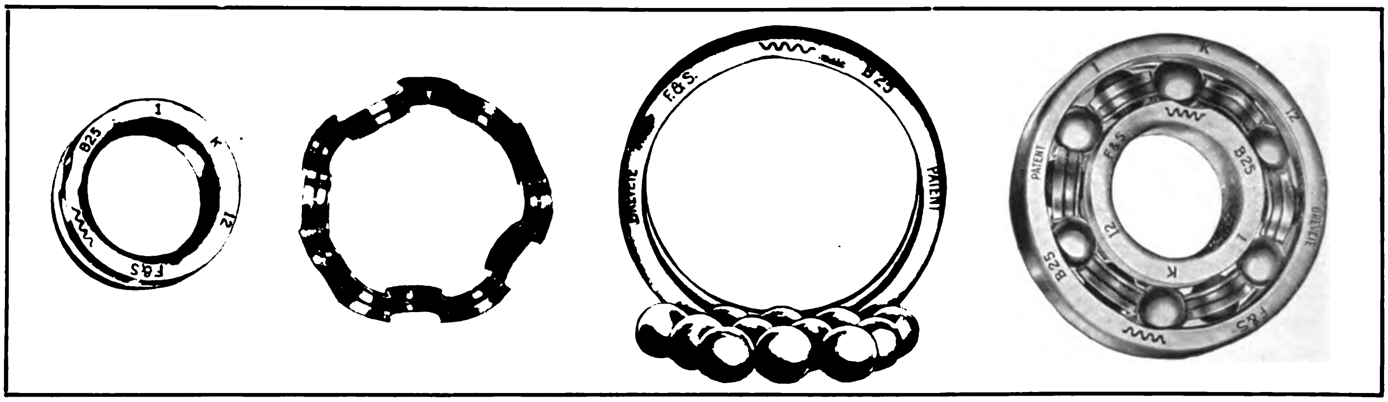
Assuming all of the previously mentioned conditions as being equal, the load capacity will vary directly with the number of balls and directly as the square of the ball diameter with corrections for the load distribution and a constant which may vary for different forms of raceways, speeds and grades of steel. Mathematically expressed the formula reads as follows:

$$P_{kg} = .24 \times K \times N \times d2$$

Where N = number of balls, d = ball diameter in eighths of an inch (i. e., diameter = 1 inch, d = 8, diameter = 5-16, d = 2.5), K a constant whose value has been obtained from a long series of tests, and .24 is the percentage of balls subject to load at a given instant. As before stated, the value of K varies with the speed. The following values are used by Messrs. Fichtel & Sachs, makers of the F. & S. bearing, and are considered quite conservative:

17— 50 R. P. M.	15— 200 R. P. M.	13— 500 R. P. M.
11— 800 R. P. M.	10—1000 R. P. M.	8.0—1500 R. P. M.
6.5—2000 R. P. M.	5.5—3000 R. P. M.	

This bearing, which is shown in the accompanying cut, has the largest load capacity of any bearing now on the market, due to the number and size of balls used. The accuracy of workmanship, separator design and high quality of steel have made it the standard of quality throughout the trade.



The F & S Ball Bearing and Its Components: From Left to Right, Centre or Shaft Collar, Separator, Ball Race and Balls and the Assembled Bearing.

AGRICULTURAL MOTOR TRIALS IN FRANCE.

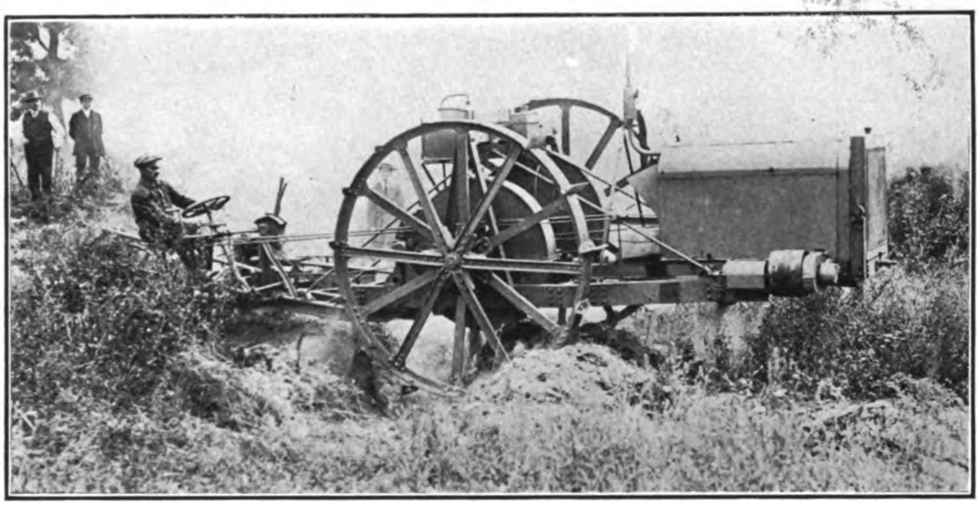
Some Interesting Designs Revealed by Second International Exhibition and Congress at Soissons---Importance Attached to Machines Suitable for Small Farms.

PERHAPS the most important test of its kind was that conducted under the auspices of the Association Francois de Motoculture, in connection with the recent second international agricultural motor congress at Soissons, France. The list of delegates attending the congress included representatives of the government, colonial and agricultural organizations in Belgium, Spain, Sweden, Greece, Egypt, Brazil, South Africa and Tunis, indicating the importance in which this phase of the industry is held in the several countries. It may be added that the French farmers appear to be eager to consider the claims of agricultural motors, largely because of their bearing upon the difficulty of securing laborers, and the possibility of securing machines which will render them somewhat independent in this respect. The same conditions apply in some of the other countries represented at the conference and were reflected in the machines on display.

In addition to the exhibition of machines for practically all kinds of farm work, some little time was devoted to an actual test under working conditions. A tabulated result of these trials is not available at this writing. It may be stated, however, that the results were in no way comparable to those that have been obtained from the agricultural trials held annually at Winnipeg, Can., for the reason that in this instance, more attention was devoted to the machines designed for light work; machines capable of plowing up to three furrows, rather than those powerful tractors employed on the large tracts in the United States and Canada. Plows, hoes, planters, reapers and mowing machines were represented, but a substantial majority of these were designed for use on the so-called small farm.

America was represented in the trials by the Holt Caterpillar tractor, made by the Holt Manufacturing Company, Stockton, Cal., this being exhibited by Jules Schnerb of Antwerp, the Continental distributor. This machine is not new in this country, having been used with much success on the western plains and in Canada, as well as in what might be regarded as smaller installations. Instead of the usual traction wheels, a chain mechanism is utilized to deposit a series of plates, from which arrangement the vehicle derives its name, so as to provide increased contact with the ground for travelling over soft and uneven surfaces.

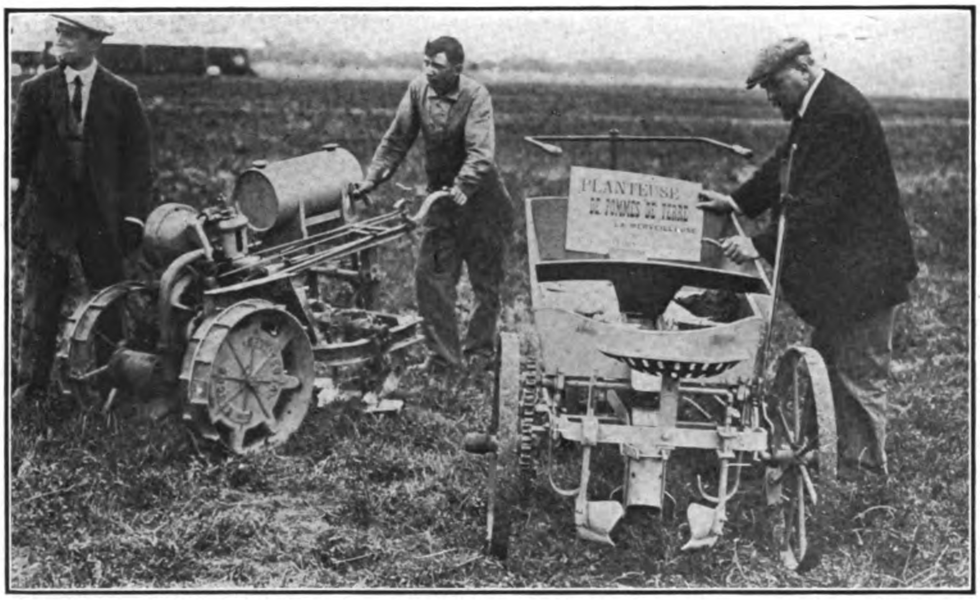
The Stock motor plow, shown by the maker, the Stock Motorflug, Ltd., Berlin, Germany, is self-contained, by which is meant that the plowing attachment is connected permanently to the frame of the vehicle instead of being hauled by the latter as a separate implement. Two driving wheels of large diameter, fitted with deep paddles to increase their grip upon the soil, are mounted at the centre of the frame, which is supported from the main axle and practically is balanced in a horizontal position. The motor, which with the radiator is carried at the extreme forward end, is rated at 42-50 horsepower, and is equipped with Bosch ignition and a carburetor designed to operate on gasoline, benzol or other similar fuels. Power is transmitted through a clutch and change speed gearing, and finally by spur gears meshing with large diameter gears on the main axle. Steering is by means of a hand wheel and irreversible gearing, which controls the movements of the single wheel pivoted at the rear and on the left side of the plowboard, which is arranged to accommodate six bottoms. This rear wheel is provided with a central flange to prevent side slipping and the steering movements are communicated to it through a long diagonal rod fitted with the usual type of ball joints. The end of the plow frame is raised or lowered by means of a rack and pinion gear operated by a long endless chain taken from a sprocket on the end of the horizontal shaft fitted with a handle in front of the driver, thus enabling one man to drive the machine and attend to the six plows. It is understood that over 700 machines of this type have been supplied by the maker for use in Germany and elsewhere.



Stock Self-Contained Motor Plow, Working in Rough Land at Soissons, France.

Vve. A. de Mesmay, Saint Quentin, France, was represented by two vehicles, one a tractor capable of hauling two plows, and the other a hoeing machine. These more nearly approach the type which is de-

signed to replace a pair of horses on the smaller farm. The tractor is mounted on four wheels, all of which are driving members, and is propelled by a two-cylinder, 15 horsepower Abeille motor located at the rear of the chassis frame and trussed on both sides by channels. Power is transmitted forward to a cone clutch, and thence by a short shaft to a gearbox under the driver's seat. A short shaft and bevel gearing transmit the power from the gearbox to a vertical shaft, at the lower end of which a bevel pinion and crown wheel deliver it to the forward wheels. The shaft and gearing are contained in a strong casing between the wheels, which for steering purposes are made to swing together by means of a bevel gearing encased and mounted at the extreme front of the frame, and controlled from the driver's seat by a steering wheel and sloping pillar. For driving the back wheels, a long shaft is taken from the gearbox, below the engine, and terminating with a worm which engages with the underside of a worm wheel on the rear axle. The drawbar is attached to bearings on this axle.



The Larger Bauche Hoeing Machine and a New Automatic Potato Planter.

The de Mesmay hoeing machine is somewhat similar in design, although its front wheels only are driven, in the manner explained above. The motor is a single-cylinder Abeille, rated at seven horsepower. Two seats are provided, one in front for the driver, and the other behind for the man who manipulates the hoes. These latter are 18 in number, fixed to a transverse shaft supported below the chassis, and raised or lowered by means of a hand lever.

The vehicles displayed by Eugene Bauche et Cie, Le Chesnay, France, were three in number, each designed to take the place of a single horse. Two of these were hoeing machines and the third a mower. All are controlled by the driver walking behind instead of riding, and all are said to have proven practical in a large number of installations.

The larger hoeing machine is propelled by a single-cylinder, four horsepower motor, driving the two main wheels in front. The engine is air-cooled by means of a rapidly rotating fan, so encased as to deflect the currents of air around the cylinder. The final transmission is by means of pinions and internally cut gear rings, and the whole of the transmission mechanism is encased and protected from dust and dirt. The rear of the machine is carried on a single trailing wheel, and between this and the engine are two transverse shafts, to which are attached the four hoes. By means of an eccentric and rod these are given a reciprocating or striking action when the machine is in motion. The smaller hoeing machine is similar in every respect, with the exception that its engine develops but 2.75 horsepower.

The Bauche mower has a single-cylinder motor rated at three horsepower, placed with its crankshaft parallel to the main axle. The drive is taken by means of spur gearing to a shaft on the right of the engine and carrying the clutch, which when engaged transmits the power to the right hand main wheel by spur gearing. By means of other spur gearing, the left hand wheel is made to drive a pair of bevels which rotate a shaft leading forward and terminating with a disc and crankpin, to which a rod is connected and made to actuate the usual form of cutter bar arranged at the extreme right of the vehicle. This cutter bar is hinged so that it may be elevated to a vertical position when not in use. The machine is guided by a pole at the rear, fitted with two handles between which is fixed a hand lever for operating the clutch. In front a simple form of mechanism permits the cutter bar to be raised or lowered as required.

Shown in connection with the Bauche machines was a potato planter, and while definite information is lacking as to the motive power for this, it is assumed that provision is made for attaching this to one of the other vehicles. The operator of the planter has a seat at the rear, handles in front to guide the machine and a lever at the right to actuate the mechanism arranged to drop the potatoes at stated intervals. Directly in front of the distributing tube is a plowshare, which digs the necessary drill, and immediately behind the tube are two hoes, so arranged that the potato is covered automatically.

A number of French makers have devoted attention to cable systems of plowing, in which the tractor is fitted with winding drums by means of which the plow is drawn across the field, or by an arrangement of pulleys the vehicle winds itself back and forth by means of a fixed cable drawing the plow behind it.

Georges Filtz, Juvisy, France, exhibited one of his Arion tractors and two cable trucks, to which the ends of the cable are attached when stretched across the field. Each truck is provided with a small drum, rotated by a handle and ratchet gear. When engaged in plowing, cables are taken from these drums and anchored some way down the sides of the field, and after each furrow has been plowed the trucks with the connecting cable can be moved by slightly rotating the drums by means of the ratchet gear.

The Arion tractor is a four-wheeled vehicle, fitted with a four-cylinder, 40 horsepower motor, driving through a clutch to a special gearbox, which transmits the power to one of two large cable pulleys carried in line with each other on one side of the frame. The plowing cable is first passed through a roller guide, mounted on one end of the tractor frame, three times around the two pulleys in the form of a figure eight, and then through another roller guide at the other end of the chassis. By this means the tractor is made to travel in either direction, and to draw the plow or other cultivating implement. A form of balance plow is utilized, so as to save time when reversing the direction of the headlands.

Another interesting and somewhat similar system is represented by the machine shown by Delieuvin et Cie, 77 Avenue de la Grand Armee, Paris, although in this case the plow only is drawn across the field. Two vehicles of exactly similar design are employed. The chassis is mounted on four large diameter wheels and carries a 10 horsepower De Dion-Bouton motor, from which power is transmitted by belt to fast and loose pulleys on a transverse shaft directly above one of the axles. This shaft is fitted with a spur pinion engaged with a spur wheel attached to a cable drum of large diameter. The cable of this drum is taken around an idle horizontal pulley, carried in the centre of the vehicle, below the frame, and about 18 inches from the ground. The vehicles are placed opposite each other, one on either side of the field to be plowed, and the cables are attached to either end of a form of balance plow, which is drawn in alternate directions across the field by means of the winding drums. As exhibited, shafts are provided and a horse is required to haul each winding vehicle down the field after each line of furrows has been plowed, although, doubtless, some method will be found to utilize the power of the motor for this purpose.

This by no means exhausts the list of agricultural motor vehicles exhibited and tested, but it suffices to indicate the various types presented. MOTOR TRUCK is indebted to Motor Traction of England for much of the descriptive matter contained herein.

GENERAL NEWS FROM ABROAD.

Lord Mayor Designs Body—In order to provide a double-decked motor 'bus which shall afford protection from the weather for the occupants of both decks, the Lord Mayor of Vienna, Austria, has designed a body of this type, which is meeting with general satisfaction in Europe. The interior seating arrangement also has been given consideration, the passengers being disposed somewhat in the form of two semi-circles, placed side by side.

Australian Motor 'Bus Company—The Melbourne Motor Omnibus Company, Ltd., has been organized with office at 352 Collins street, Melbourne, Australia, to operate a fleet of motor 'buses in that district.

Good Road in Nigeria—According to the African World, an attempt is soon to be made to establish a regular service of motor vehicles between Kano and Katsena in Nigeria, Africa, a metalled road 95 miles in length having recently been constructed.

French Subsidy Awards—Official announcement from the French minister of war shows that the following vehicles successfully passed the recent tests for subsidy awards: Delahaye, with four vehicles of one type; Latil, with four vehicles, representing one truck and a four-wheel driven tractor; Saurer, with two vehicles of two types; Berliet, eight machines of four types; Panhard et Levassor, De Dion-Bouton, Delaugere et Clayette, Brasier, La Buire, Peugeot and Aries, each with two machines of one type. This year's trials brought together 72 machines, of which 68 finished and 38 were awarded subsidies.

Bauche Mowing Machine, Utilizing Single-Cylinder Motor.

Commercar Supersedes Coach—Despite the sentiment attaching to the old time stage coach, which has operated between Campbelltown and Tarbert, Scotland, for over 40 years with but one failure to complete its daily journey in that time, this has now been superseded by a service of Commercar motor 'buses.

Fire Engines in Japan—In reply to an expert attached to the German consulate at Yokohama, Japan, who suggested that makers of motor driven fire engines might find a good market in that country, an English engineer states that the narrowness of the streets and their labyrinthine character preclude the universal application of such vehicles as are produced

in Great Britain, for instance. He adds that in order to have any chance of success, such machines must have the flexibility of the two-wheel, coolie drawn cart, and the motor must deal with a suction depth of say 17 feet and pump water through a hose 49-62 feet to a distance of 98-131 feet and to a height of 39-49 feet.

New Customs Regulations—Under the South African Union customs management act of 1913, it is provided that invoices for goods shipped to South Africa must contain, in addition to the invoice value, a statement of the "current value for home consumption in the open market for similar goods at the place of purchase."

Motor Service in Ireland—Sir Henry Grattan Bellew is chairman of the committee representing merchants in the Mount Bellew district of Ireland, for the organization of a company to operate a fleet of motor vehicles for passengers and freight in North-East Galway. The expense and delay of the present railway facilities is responsible for the movement.

French Export Statistics—The official figures for the exportation of commercial motor vehicles from France during the first half of 1913 show a total value of such exports of about $2,000,000, as compared with about $625,000 for the corresponding period in 1912. Belgium is the principal market, followed by Germany, Brazil and Argentina. The exports to Turkey and Switzerland indicate a decrease.

South Australian Farm Wagons—It would appear from recent advices from South Australia that there was a profitable field to be worked among the farms in that section. In the vicinity of Mount Lofty three enterprising farmers recently have purchased machines with which they transport their produce to market. When not busy in their own work these men find abundant opportunity to haul produce for their neighbors.

French Army Competition—The French war office has given notice of a competitive test of four-wheel driven machines early in February, 1914. The vehicles must be of French manufacture and constructed according to details already furnished the makers. It is understood that the producers of the Latil, Chatillon-Panhard, Balachowski et Caire, Schneider, Renault and Crochat will take part.

Truck Show in Paris—While the annual Paris Automobile Salon in the Grand Palais will be devoted entirely to a display of pleasure vehicles, the management of the show has taken cognizance of the growing interest in commercial cars, and a special building will be erected in the Cours la Reine, where such machines will be exhibited, Oct. 17-27, during the progress of the annual showing in the Grand Palais.

THIRTY-EIGHT CENTS A TON.

That Is What It Costs Battle Creek Concern to Haul Its City Freight.

Believing that the general public would be interested in its experience with a three-ton motor truck in hauling city freight, the transportation superintendent of the Kellogg Toasted Corn Flake Company, Battle Creek, Mich., has issued a statement, in which the name of the vehicle has been eliminated purposely. The object in this instance has been to present figures that could not by any means be traceable to the manufacturer of the truck.

During the three years this machine has been in service it has averaged one set of tires a year, and the repair bills in that time have totalled less than $50. No charge has been made for depreciation, the superintendent maintaining that the truck still is in efficient condition. The machine is utilized in carting freight between the factory and the freight depots in Battle Creek, and for the delivery of less-than-carload lots in the city and immediate vicinity.

The figures for the month from July 7 to Aug. 5 show that 259.3 tons of freight were handled at a cost of 38 cents a ton. These figures include charges of $78 for labor, $18.72 for gasoline and $2.14 for oil. The record of the truck's performance for this period follows:

July—	Gallons gasoline.	Oil	Freight hauled, pounds.
7	5	1 quart	22,725
8	4	1 quart	22,790
9	5	1 quart	23,452
10	5	1 quart	18,318
11	5	1 quart	19,661
12	4	1 quart	15,344
14	4	1 quart	23,685
15	5	1.5 pints	27,645
16	5	1.5 pints	16,147
17	5	1.5 pints	17,910
18	5	1 quart	19,060
19	3	1 pint	10,418
21	4	1.5 pints	22,150
22	6	1 quart	28,006
23	5	1 quart	20,009
24	4	1.5 pints	22,127
25	4	1.5 pints	20,352
26	4	1.5 pints	16,595
28	6	1 quart	30,207
29	3	1 pint	11,168
30	3	1 pint	6,508
31	5	1 quart	19,572
August—			
1	5	1.5 pints	18,285
2	6	1 quart	27,746
4	4	1.5 pints	20,863
5	3	1.5 pints	17,886
Total	117	21.5 quarts	518,629

The Kaufmann-Bear Company, which has established a new department store at Pittsburg, Penn., has placed an order with the White Company, Cleveland, O., for 38 wagons and trucks of different capacities, and is to supplement this with 20 additional machines later on. The initial order of 38, however, is to be delivered as quickly as is practical. When these machines shall be delivered there will be a total of more than 160 White vehicles in service in Pittsburg.

Municipal Service Equipment

BROWN FUNERAL CAR.

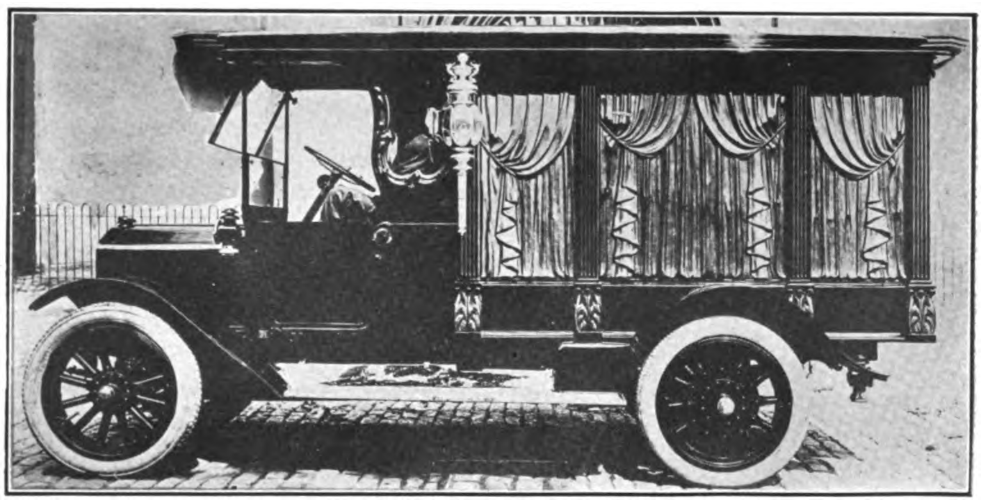
Indiana Manufacturer Finds Demand for This Product Is Increasing.

Something like a year ago, at the annual convention of funeral directors in the Middle West, action was taken looking toward a more general adoption of the motor vehicle. At that time the delegates to the convention were not prepared to state definitely that motor driven hearses would entirely supersede those drawn by horses, but it was the consensus of opinion that it was wise to give the subject deliberate consideration. Of course, motor driven casket wagons have been in service in all sections of the country for some time.

An accompanying illustration presents a funeral car—a name which appears to have entirely superseded the older term with the appearance of the newer type of vehicle—made by the Brown Commercial Car Company, Peru, Ind., for A. Geissel & Sons, a funeral director in Philadelphia. The chassis is standard, but it will be noted that it is mounted on pneumatic tires, and other provisions made for easy riding qualities. The appointments are quite as ornate as with the horse drawn vehicle, and in every respect there appears to have been a careful consideration by the designer of the use to which it will be put.

This car took part in the recent motor truck parade in Philadelphia and attracted much favorable comment. Will H. Brown, president of the company, who recently returned to the factory from a visit to New York City, announces that he has orders on hand for several of these vehicles for delivery in the East.

Another new Brown vehicle is illustrated herewith, this being a combination chemical engine and fire wagon. Mounted on a light weight chassis, this is designed for use where it is desirable to have a fast machine available for answering alarms. The equipment is such as to take care of incipient brazes before they have reached serious proportions.



Brown Funeral Car Recently Delivered to an Undertaking Concern in Philadelphia.

AMBULANCE A LIFE SAVER.

Worcester Surgeon Gives Abundant Evidence to Substantiate This Claim.

That the ambulance in service with the police department in Worcester, Mass., is a life saver, seems to be abundantly proved by the testimony of Police Surgeon Richard J. Shannahan. This is a phase of the situation which is not always given the consideration it merits, when city officials are estimating the probable cost of new apparatus. Dr. Shannahan says:

Only the other day we had a case of asphyxiation and to the police automobile ambulance can be laid the fact that the man's life was saved. We went out on the call before discovering the necessity for the pulmotor, and had we been compelled to wait for a horse drawn vehicle to bring it, so much time would have been taken up that the man would have been dead long before it arrived.

This is only one of a dozen such cases we have had recently. We had a drowning accident in Quinsigamond last week, and if we had not had a fast car the child who figured in the accident would have been dead when we got there. As it is, the child is as well as ever. We can make the trip to the lake from station 1 in four minutes. One night recently we made the trip to the lake, spent five minutes in attending to the patient, took him to the city hospital and was back in the station in 20 minutes from the time we left it.

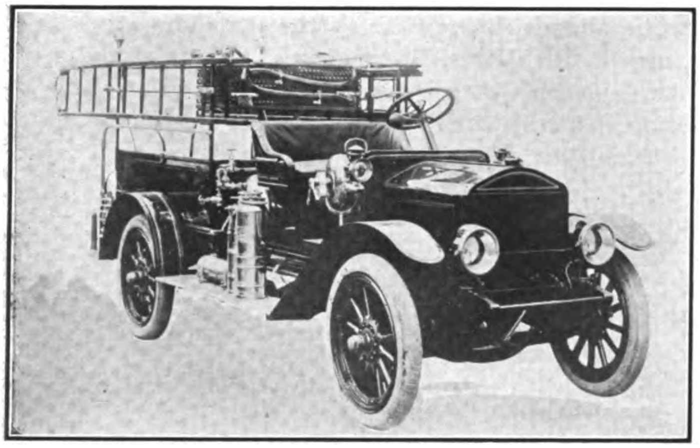
The motor driven ambulance is a great advantage over the old horse drawn wagon in winter, because we utilize the exhaust from the motor to heat the interior, and the patient is much more comfortable as a result. Patients also are benefitted by the fact that the present ambulance is smooth riding, while the vehicle behind galloping horses gives a good deal of jouncing and jerking that is not appreciated by the man or woman who is badly injured or is ill.

Dr. Shannahan is authority for the statement that Worcester is soon to have a new ambulance, one which he believes will be the only one of its kind in the state. Besides other modern improvements, there will be a reservoir on top of the car and a sink in one corner of the interior, so that hot water always will be close at hand. He says it is the only machine of the kind in use, except those owned by the Bellevue Hospital in New York City.

STUDYING GARBAGE DISPOSAL.

Engineers of the Knox Company Offer Solution in Knox-Martin Tractor.

Within the past few months the subject of garbage disposal, and the relation of the motor vehicle thereto, has been given serious consideration by a large number of cities. The engineers of the Knox Automobile Company, Springfield, Mass., have been giving the matter extensive study, and believe they have the proper solution in the use of Knox-Martin tractors,



Brown Combination Chemical Engine and Hose Wagon.

several of which have been installed in this class of civic service.

In the Knox plan the horse carts collect the garbage from house to house, but instead of making the long, hard haul to the refuse plant, which usually is located in the outskirts of the city, each team draws its loaded wagon to a convenient junction point, where the body is jacked up at the forward end. The king pin is removed and the team with the forward axle is attached to an empty wagon, which has been jacked up similarly and is waiting.

During the night, or at any other convenient season, the tractor picks up these loaded wagons and hauls them to the refuse plant. An additional advantage in this method is found in the fact that the wagons being covered, there is no objection concerning the odor and no dropping of particles of garbage, as is necessary where the load must be transferred from one vehicle to another, which is sometimes done to avoid the long haul with the horses. It also is pointed out that there is considerable saving in economy, since one tractor can do the work of several horses.

PRAISES WHITE PATROL.

Superintendent Pierce of Boston Police Department Says It Has Given Entire Satisfaction.

William H. Pierce, superintendent of the police department in Boston, Mass., is authority for the statement that the cost of maintaining the White police patrols in that city has been very slight. He adds that the city has three of these vehicles and has ordered two more.

The first White patrol in Boston was placed in service June 5, 1912, and its total mileage to Sept. 1 was 9588 miles. The capacity is one-ton and it will carry 12 officers. Besides using the wagon for arrests, it also is employed for transporting prisoners from the Hyde Park police station to the court house in Jamaica Plains, a distance of six miles, and it is used for this service every day.

"In my opinion," says Superintendent Pierce, "the weight and carrying capacity of the wagon is the proper standard for the purpose for which it is used." Before purchasing a car for this department, investigation of various makes was made, and the officials came to the conclusion that the White was the best adapted to the work. "It is giving us entire satisfaction," is the superintendent's statement. "In fact, we are justified in saying that we cannot speak too highly of the White gasoline patrol wagon."

TIRES FOR FIRE WORK.

Goodyear Official Offers Some Suggestions Concerning This Class of Service.

F. H. Sawyer, manager of the fire truck tire department of the Goodyear Tire & Rubber Company, Akron, O., is of the opinion that the abandonment of the horse drawn fire apparatus is inevitable. He bases this conclusion largely upon the fact that it is now possible to transform the present equipment into motor driven apparatus at comparatively slight expense through the use of tractors.

He cites the fact that millions of dollars are invested in horse drawn apparatus, which would be entirely lost were it not possible to secure the benefits and advantages of a motor driven piece through the use of a tractor. This means, of course, the retention of practically the original equipment, with the exception of the front wheels, and obviates the expense of purchasing an entirely new machine. Mr. Sawyer says:

In fire department service the most important requisite is reliability. The demands of fire apparatus in responding to a call are imperative, and the machine must get to the scene of the fire without delay. In dealing with reliability, tire equipment is essential. It must be borne in mind that the problems involved in fire department service are far different from those encountered in pleasure vehicles. Motor driven fire apparatus weighs four or five times the average weight of a touring car, and the combination of excessive weight and high speed demands tires that contain the correct design and highest quality of workmanship and material. No tire can be a success if it fails to meet fully these requirements.

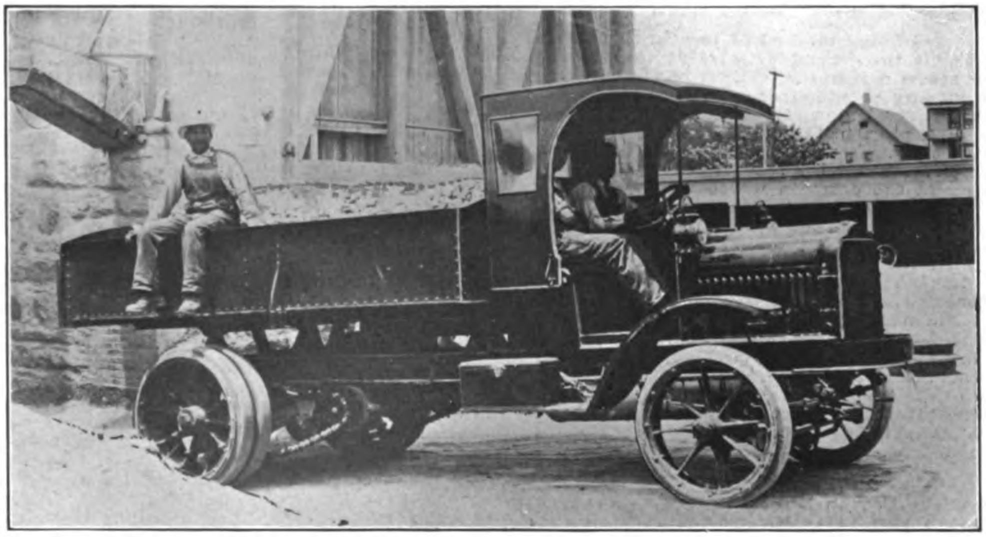
Incidentally, the question of tire expense is affected in a decided manner by the use of tractors, an added factor of interest when considering the question of motorizing existing equipment.

SAVES 16 CENTS A TON.

City of New Bedford Finds White Truck an Economical Proposition.

Officials of the street department in New Bedford, Mass., purchased a three-ton White dumping truck, through the local agent, the Auto Supply & Selling Company, last June. The machine is utilized in hauling road making materials, and the dumping mechanism is so arranged that it is operated by the power of the motor, thus making it possible for one man to do all the work.

Superintendent C. F. Lawton reports that the truck has fulfilled all expectations in the matter of reducing the department's hauling charges. On the first job, where it was used in transporting cracked stone, the cost a ton was reduced from 21 cents to five. Since that time, and in similar work, the machine has shown a transportation cost of less than four cents a ton. Mr. Lawton explains that these savings have been made on hauls of moderate length, and that they would have been somewhat larger on long hauls. "We find the truck is available for quite a variety of jobs and has proved its economy wherever used," he says.



White Three-Ton Dumper in Service with Street Department in New Bedford, Mass.

The success which has attended the use of this truck has been such that the city is now considering the purchase of additional White machines.

NEWS FROM VARIOUS CITIES.

Knox-Martin Tractor for Lynn—The fire department in Lynn, Mass., has taken possession of the Knox-Martin tractor, built by the Knox Automobile Company, Springfield, Mass., for use with its hook and ladder truck.

Selects A. & B. Tractor—Making its selection from five bids, the city council committee on fire department in Beverly, Mass., has decided to award the contract for a new motor tractor for the engine at the West street station to the American & British Company, Providence, R. I.

Malden Considers Purchase—The board of aldermen in Malden, Mass., has before it a request from Police Commissioner Warren for an appropriation of $3000 with which to purchase an automobile patrol wagon, and another appropriation of $3600 for an automobile ambulance.

Buys Two White Ambulances—Dr. A. C. Thomas, superintendent of the New Haven Hospital, New Haven, Conn., has purchased two ambulances, and expects to be able to extend the service of the institution to include the towns of Branford, Orange, Milford, Shelton and Ansonia. The chassis will be built by the White Company, Cleveland, O., and the bodies by M. Armstrong & Co. of New Haven.

Considering Electric Patrol—The city commissioners of Pensacola, Fla., are considering the advisability of purchasing an electric patrol wagon for the police department. The present wagon has three drivers, the salary for whom totals over $200 a month, while three horses are fed at a cost of $50 a month. It is estimated that all of this expense would be eliminated with the acquisition of the electric patrol, since the policeman now designated as wagon officer accompanying the vehicle would be able to drive as well as assist in making arrests.

First of Its Kind—The fire department in Burnham, Penn., recently took delivery of a fire department wagon assembled by the Shaffer Wagon Works, 5 North Cameron street, Harrisburg, Penn. The chassis was made by the International Harvester Company of America. The body was constructed to the specifications of the Burnham officials, and is said to be the first of this design to be built.

Wants Ambulance, Too—The fire department in Haverhill, Mass., recently placed its newly acquired motor fire fighting apparatus on public exhibition, alongside the horse drawn ambulance owned by the city. Instantly, there arose a demand for a modern vehicle to replace the antequated hospital wagon.

New Commercial Car Accessories

A-B Magnetic Trouble Lamp.

The Adams-Bagnall Electric Company, Cleveland, O., is marketing an electric trouble or inspection lamp that differs from usual design in that it is of the magnetic type, and when its base is placed in contact with iron or steel, it will stick. This is due to magnetism and it is claimed that the magnet has a pull of 13 pounds. The device makes for convenience in that it may be placed as desired, to project the rays of light onto the work and to permit of the use of both hands when making adjustments or repairs. The magnet is covered with aluminum and the silver plated reflector is 2.5 inches in diameter. It is equipped with a flexible lamp cord and terminals for attachment to the storage battery.

Se-ment-ol.

The Northwestern Chemical Company, Marietta, O., is marketing Se-ment-ol, a chemical preparation which is a powder that is soluble in water, but which congeals when exposed to the air in liquid form. It is utilized for stopping leaks in the radiator or other components of the water cooling system, being poured into the cooler and circulated by running the engine. When it comes in contact with a leak it forms a cement in a very short time. It is stated by the maker that it will not injure the radiator or impair its efficiency. Much of the deposits caused by the use of hard water are removed by its use. It comes in small packages and is inexpensive.

Dalitz Spark Plug Tester.

The usual method of locating a missing cylinder is to short circuit the secondary wire at the spark plug. When utilizing a screw driver for testing, one is likely to receive a shock unless care be exercised. The Dalitz Manufacturing & Sales Company, 803 Union street, Seattle, Wash., is marketing the Dalitz spark plug tester, which is a simple device for attachment to the plug. It comprises a flat strip of metal, having at one end a terminal for the reception of the secondary wire, and an opening at the other in which is inserted a movable arm of metal. This arm is equipped with a non-conducting handle, preventing any possibility of shocks when using the device. To cut out the ignition to a cylinder the movable arm is slid downward until its end comes in contact with the base or shell of the plug. This effectually grounds or short circuits the current, preventing it reaching the air gap. The device may be utilized for a number of other purposes, including that of testing the strength of the secondary current. This is performed by moving the arm in proximity to the base of the plug and noting the intensity of the spark. The tester may also be employed to note the compression of each cylinder when in operation, by the strength of the explosion. Another use for the device is locking the ignition. This is accomplished by grounding each arm when the car is left unattended.

Dayton Valve Lifter.

The Dayton Malleable Iron Company, Dayton, O., is marketing a new valve lifter which is a U shaped member with integral tapered points. It may be utilized in the conventional manner or to compress the spring by inserting the points between the coils. It is operated by a wing headed screw bolt having sufficient leverage to compress the spring with a minimum of effort, and one of the features of the device is that both hands may be used in displacing the locking mechanism of the valve, the tool remaining in a locked position. The maker states it will fit all types of motors.

Gallagher Carburetor.

The Gallagher carburetor is manufactured by the Gallagher Carburetor Company, Inc., 1876 Broadway, New York City. It is mechanically operated without springs, cams or balls, and it is stated that there are no automatic movements to be affected by fuel and atmospheric changes. The supply of fuel and air is regulated mechanically and all parts are adjustable to meet the requirements of service. Two jets are utilized, one a fixed member and the other a mechanical, the latter coming into operation when the throttle is opened. The fuel supply to this jet is operated independently from the fixed member by a mechanical needle which comes in contact with the nozzle when the throttle is opened, admitting gasoline in proportion to the air. The fixed nozzle is supplied with fuel by a set needle valve and it has its own air intake. It is utilized for starting purposes and low motor speeds. The needle valve controlling the flow of fuel to the float chamber is adjustable by simply removing a screw cap. Provision is made for hot air or hot water heating, or both. It is stated that the carburetor is easily adjusted and provides maximum efficiency with a minimum consumption of fuel.

Fogg Horn.

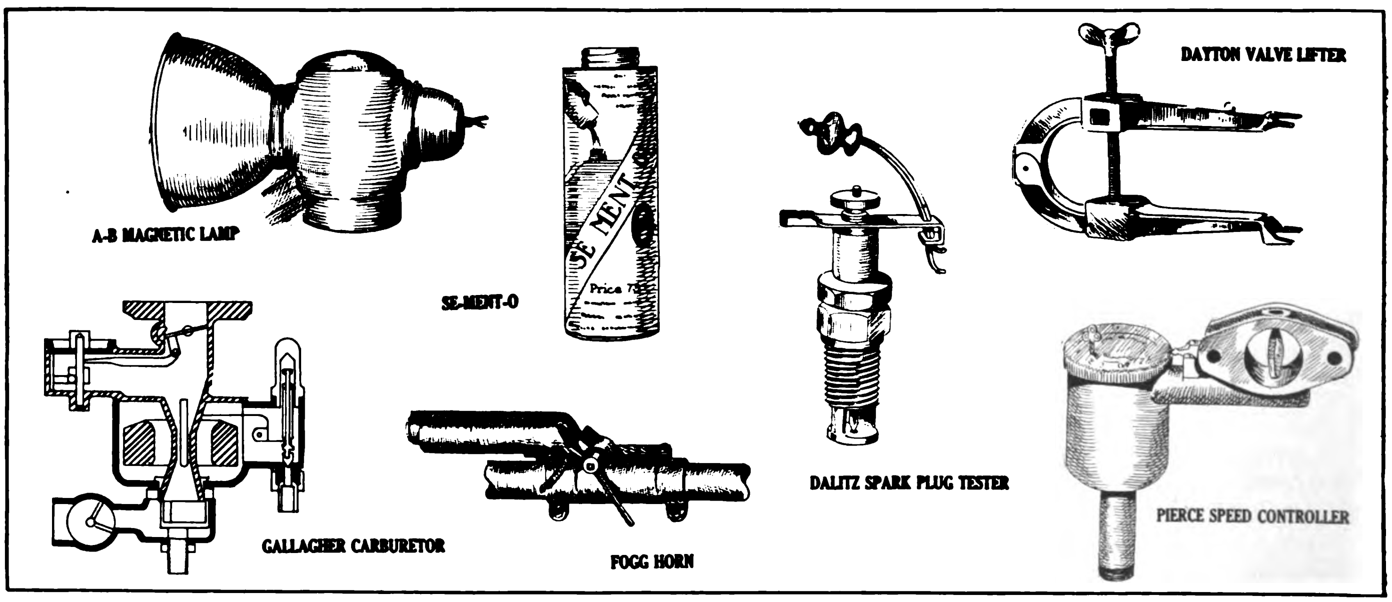
Although designed for model T Ford automobiles the Fogg horn manufactured by the Motor Specialties Company, 2 Cooper lane, Waltham, Mass., may be fitted to other cars. It is operated by the exhaust gases, is very compact and well designed. It is a simple construction and is installed between the engine and the muffler so that a leak in the latter does not affect the efficiency of the signal. The horn is so arranged that the sound is thrown forward, not backward, insuring a volume of tone, even with the motor operating slowly. There are few moving parts, and no opportunity for back pressure or clogging. It can be installed so that it does not interfere with the use of the usual cut-out.

Pierce Speed Controller.

A form of governor, differing from conventional practise in that it can be set for different speeds and locked, the owner retaining the key, is the Pierce speed controller, manufactured by the Pierce Speed Controller Company, Anderson, Ind. It is mounted between the carburetor and the intake manifold and regulates the supply of fuel by means of a butterfly valve. The last named component may be so set as to limit the vehicle speed as desired, a dial being incorporated for adjusting the mechanism, and fitted with a lock. The device does not affect the speed of the machine until the set speed is exceeded. All parts are enclosed so as to be dust, water and tamper proof. The price varies according to size.

Defiance Lock.

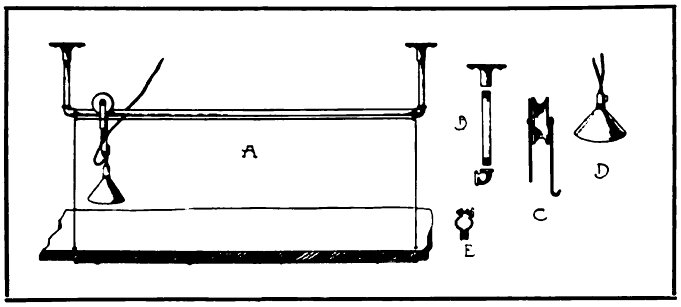
The Defiance lock is marketed by The Defiance Manifold Lock Company, San Francisco, Cal., and is a controllable cut-off valve fitted to the intake manifold. The locking device is provided with a key which is removable. The Defiance lock is made in several sizes and may be fitted to any make of car.



Illustrating Some of the More Recent Accessories Adapted to Commercial Vehicles, Repair Shop, Etc.

HINTS FOR PROPER MAINTENANCE.

A WELL lighted work bench is essential to the garage and repair shop, and while the majority of installations provide a drop light, two or more of the



Working Plan of Adjustable Light for Work Bench: A, Showing How Light May Be Moved as Desired; B, Supporting Arm; C, Pulley; D, Lamp; E, Cable Carrier.

lamps may be fitted when the bench is very long. The disadvantage of a fitted light is that the workman is often obliged to move the work under the lamp, and when he wishes a tool at the other end of the bench must swing the light in the direction of the object sought.

In an accompanying illustration is shown a method of constructing a light rack over the bench, the sketch at A depicting the operation of the light, and it will readily be seen that it is possible for the workman to be at the extreme right of the bench and roll the lamp to him by means of the cable located under the bench, as shown in the drawing. Some benches, however, would not be adaptable to its use.

The rack is easily constructed and the material required is not expensive. It consists of small gas piping, two standards and a like number of elbows. The material could be replaced with round iron, drilling and threading the parts to fit plates which are secured to the ceiling or wall, according to the location of the work bench.

A supporting arm is shown at B, while the pulley member is illustrated at C. The latter is provided with a hook for attaching the lamp cord and has an extension on the opposite side to retain the pulley on the rod. It is not necessary to fit the cable carrier as shown at E, as the light could be moved by hand as desired. The cable was fitted in the installation noted by the writer, and the inventor of the plan states that it was extremely handy when he wished the use of the lamp at the other end of the bench. In addition to making for convenience, the device is economical, as one light may be utilized in place of two or more.

INGENIOUS GEAR PULLER.

Difficulty is sometimes experienced in drawing timing gears, etc., from their shafts owing to the lack of a suitable tool. Sometimes the wheel is lightly constructed with delicate spokes and to attempt to draw the gear with the ordinary tool usually results in buckling or throwing it out of alignment. In an accompanying illustration is shown a gear puller, the maker of which was awarded first prize in the mechanics' competition conducted by Commercial Motor, an English motoring print.

It is stated by the maker that it will remove a gear without injuring it, as an even pull is obtained at four separate points of the rim when required. This is accomplished by inserting three-quarter pins through the arms of the top, on which the wheel can be placed. When the gears are solid and will withstand more strain, the other end of the dog, with the bent-over legs, is utilized in the usual manner. When the gear has openings the reversible dog may be used as well.

CARE OF SHELLAC.

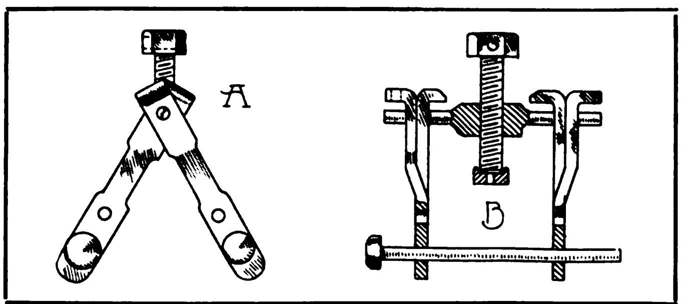
Shellac is very useful in the garage and as it dries up very quickly it should not be exposed to the air. Place it in a bottle and fit a wooden stopper. The latter may be utilized for smearing the liquid when its service is required.

RESTORING DRY CELLS.

Various suggestions have been made for temporarily restoring apparently dead dry cells, among which may be mentioned drilling through the sealing material and moistening the depolarizer with a little water and vinegar. The following hint is given by a battery concern: Take a hard piece of wood and with a light hammer drive down the material surrounding the carbon post. It is said that amperage is increased considerably by this action.

WRISTPIN CLAMP.

The usual method of removing a wristpin from its connecting rod in the overhaul of the motor is to utilize a piece of brass and a hammer, driving out the wristpin. This is not held to be good practise owing to the walls of the piston being fragile and the possibility of damage through carelessness. In an accompanying

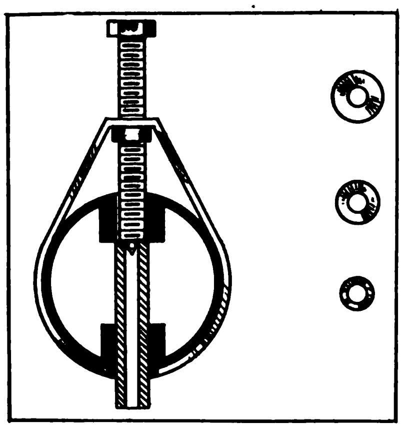


An Ingenious Gear Puller: A, Showing Construction of Device; B, How Four Points of Contact Are Obtained.

illustration is presented a wristpin drawing tool which was constructed by a driver who cares for several machines utilized by a concern with which he is em-

ployed. The device is easily constructed.

It comprises a clamp as indicated, which is slipped over the piston. The clamp carries a threaded bolt, the end of which is turned down to a point and engages with the wristpin when this is of the solid type. By using a wrench, a gentle but considerable pressure is brought against the wristpin and it is stated that the most obstinate part may be removed without danger of injury to the piston. When constructed for the repair shop several sizes of pins could be turned out to meet varying designs of wristpins, including hollow members.



Clamp for Withdrawing Wristpins from Piston.

EFFICIENCY OF DRY CELLS.

The efficiency of dry cells wired in series or multiple series is impaired if one or more of the set is decidedly below the average of the others. Test each cell with an ammeter and throw out any that fall considerably below the others.

Occasionally one will purchase a screw driver the blade of which is too soft. While they should be hardened to a degree of toughness, beyond that is not necessary, as they are not called upon to do any cutting. When water is used for hardening it has a tendency to make the metal too hard. Oil is superior. If water is to be used it should be heated until it nearly reaches the boiling point.

Brittleness of small tools, drills, taps, etc., may be prevented and economy effected by plunging the part into a cake of soap or wax after hardening when being cooled.

GARAGE AND SERVICE STATION EQUIPMENT.

THE Canton Foundry & Machine Company, Canton, O., is manufacturing a wide variety of turntables and in various sizes and capacities. One of the features of the Universal design, shown in an accompanying illustration, is the inexpensive foundation required and the means employed to take care of the accumulation of mud, etc., removed from the vehicle in the washing process. The pit is but 12 inches deep with concrete base, slightly larger than the turntable, and grooved so as to carry all water and debris from the centre to the periphery of the table and into a concrete gutter or drain, which is covered with removable plates.

It is held that the Universal operates so easily that it may be turned by a child. This is due to the serpentine, patented, ball bearing race course, so constructed that foreign elements are prevented from interfering with the movement of the balls. By referring to the lower view in the illustration it will be noted that the top of the table rests on seven balls at the summits, the remaining balls revolving in pockets filled with lubricant. As the table moves the balls at the "high spots" roll and are replaced by others coming up, eliminating friction.

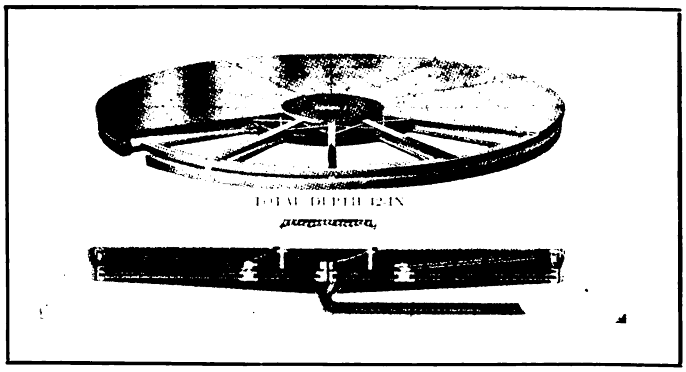
The superstructure is of structural steel built in truss form and reinforced. The top plates are No. 7 gauge steel, securely braced. The table has a checkered iron removable centre with No. 7 gauge steel plates extending to the outer rim, neatly fitted and sloping slightly to provide for proper drainage. The 12 top steel plates are removable and are reinforced by angle irons at proper intervals, firmly riveted crosswise underneath and resting on structural trusses. The table cannot tilt, as the slightest depression throws caster wheels on the outer rim to the rim track. The Universal is made in 12, 14, 15 and 16-foot table diameters, each having a supporting capacity of 8000 pounds, and 16 and 18-foot diameter tables with capacities ranging from eight to 10 tons for truck service.

HARDY RATCHET WRENCH.

A wrench operating on the ratchet principle is the Hardy, marketed by the Hardy Manufacturing Company, Pendleton, O. It is an all-steel tool having five parts, these comprising a handle, two side plates, a ratchet socket and a rivet. The latter is employed to secure the side plates to the handle.

F. & R. PATENT VISE.

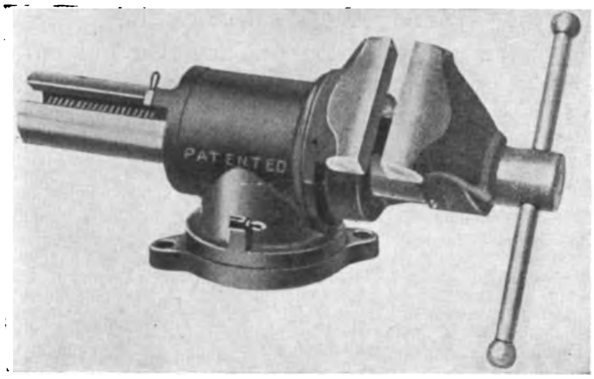
The Fulton Machine & Vise Company, Lowville, N. Y., is manufacturing the F. & R. patent vise in the machinist's pattern. It has the advantage of two complete swivels, a combination of the two giving the



Universal Turntable, Having Ball Bearings and Means for Draining, Is Constructed in Varying Capacities.

most desirable positions for its use by a mechanic. The vise, which is presented in an accompanying illustration, is locked at any angle by two separate methods.

One is by clamping the work within the jaws, which tightens the frictions, the other by the use of the position pins. With both in use it is stated that the vise is



F. & R. Patent Vise Especially Adapted for Motor Car Repair Work.

positively locked in any position. The jaws are always held in place, when the work is removed, by the piston pins, if the operator requires, by the use of which the vise is made stationary at any angle. Cast steel faced tempered jaws are utilized. The vise is made with openings varying from two to nine inches and in six sizes, the weights varying from 6.5 to 155 pounds.

EDWARDS PORTABLE TIRE PUMP.

The Edwards Manufacturing Company, Cincinnati, O., is producing the Edwards portable electric tire pump shown herewith. It is simple in design and throughout the best of material and workmanship are employed. The motor, compressor and tank are mounted on a neat base having three wheels and a convenient handle. The air tank is 12 inches long and six in diameter, and is equipped with a petcock at the bottom, permitting of blowing out any condensation that may exist, also for pumping into the tank direct.

The motor is a .5 horsepower unit, constructed for either alternating or direct current, 110 or 220 volts, 60-cycle, single-phase. The compressor is of the air-cooled type, geared to the electrical unit, with pinions fully enclosed. Eight feet of high grade .5-inch hose with gauge, tank pressure gauge and 20 feet of electric cord and socket are included in the equipment. The switch is located on the motor. Lubrication is provided by means of grease cups on the cylinder and crankshaft bearings. It is stated that the outfit will pump a 34 by four-inch tire from flat to 70 pounds in 90 seconds. The weight of the equipment is 130 pounds. The company issues a catalogue on portable tire power pumps, grinders, drills, etc., which will be forwarded on request.

NEVER LOOSEN LOCK NUT.

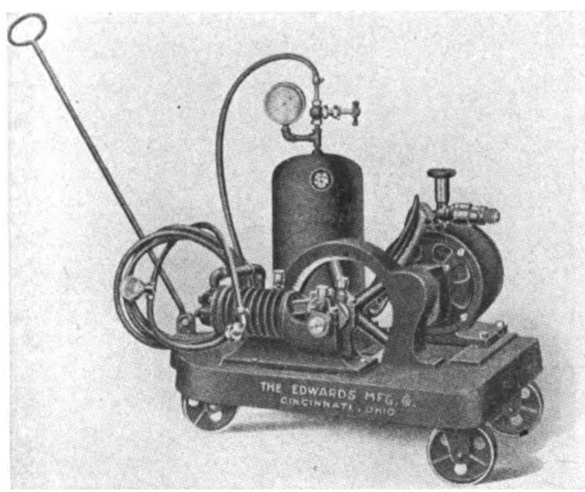
L. L. Swenson, Ottuma, Ia., has invented a lock nut device, termed the Never Loosen, which comprises a split nut having threads for engagement with the bolt threads and adapted for binding engagement on the face of the nut proper, preventing turning of the nut. The locking action is secured by the twisting of the locking nut before the threads are cut. The nut proper is constructed of hardened tempered steel so that when applied to the bolt it will have a tendency to resume its normal shape, thereby locking both the nut and the bolt.

J-M MOBILENE PACKING.

The H. W. Johns-Manville Company, New York City, is marketing the J-M mobilene sheet packing, which is designed for service where extremely high temperatures are encountered, such as the exhaust manifold, etc. The packing is constructed of asbestos with fine brass wires intertwisted in each strand. It does not burn or char and one side is graphited. It is pliable, easy to cut, and being compressible makes for a tight joint. It comes in rolls 40 inches wide and .03125 thick.

SCHWARZ WHEEL SPIDERS.

The Schwarz Wheel Company, Philadelphia, is now marketing its wheel spiders, enabling repairs to be made by the garageman. They are adaptable for renovating wheels which have a number of spokes broken, thereby saving time and the cost of shipping the work to the factory. The spiders are constructed with the Schwarz patent spoke, and these spokes, turned, finished and assembled, form a complete filling for the wheel, with the exception of the felloe. In repairing wheels, it is stated that all that is required is to cut on the round tenons, and put on the old felloe and metal rim. The spiders may also be used in producing new wheels by simply applying new felloes



Edwards Portable Electric Tire Pump, a Simple and Compact Outfit.

amid the metal rims. The centre hole to be bored by the hub is left blank. The spiders are long enough to accommodate any size of pleasure or commercial tire.

CORRESPONDENCE WITH THE READER.

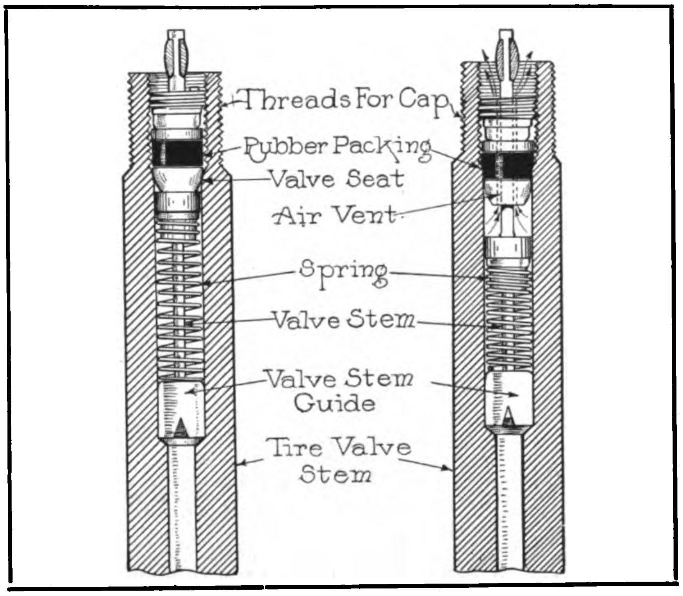
Leaks in Pressure Feed System.

(47)—Some time ago the concern I work for purchased a second hand pleasure car and fitted a body for delivery work. Until recently it has given good service, but I am experiencing trouble in keeping the pressure up and now have to use the hand pump every few miles. Where shall I look for trouble? What causes a tire to soften when the tubes are good and do not leak? J. D. E.

Stamford, Texas, Sept. 17.

The failure of the pressure system is due to leaks and it is probable that a connection has worked loose. An excellent method of locating the leak is to make a solution of soap and water. Pump up the pressure to about 1.5 pounds and apply the mixture to all joints and connections, noting if any bubbles are given off. If any exist, disassemble the part and examine it, replacing with new if found faulty.

It may be that the check valves are dirty. Remove the pipes and test them, also clean the valves. Generally pressure feed systems have a regulating valve, adjustment of which may cure the trouble, providing leaks are not discovered by the soap treatment. The check valves may be tested with gasoline. Excessive lubrication of the motor may be responsible for some of the trouble mentioned.



Sectional Drawings of Valve Stem Showing Function of Components with Valve Seated at Left and Open at Right.

The trouble experienced with tires is due to the valve and this member may be tested by immersing it in a tumbler of water and noting if bubbles are given off. By having the valve stem in an inverted position it is a simple matter to employ the water test.

The failure of valves is largely due to their not being handled properly. Dirt will find its way into the valve mechanism, preventing its seating properly. In an accompanying illustration are shown the components of a valve, the view at the left showing the valve seated; that at the right the plunger depressed and air flowing out as indicated by the arrows.

If the valve proper is prevented from seating by the presence of foreign elements, a slight leak such as mentioned will occur. The seat should be cleaned, an operation requiring the removal of the valve. Sometimes a leak is caused by the rubber packing being bruised and this condition is usually due to screwing in the valve too tightly, a practise that not only destroys the rubber, but makes inflation more difficult. Unless the valve can be repaired it is best to fit a new one, as these members are not expensive.

Switch at Fault.

(48)—What causes the motor to sometimes continue to run after the switch has been moved to the off position? I am driving a machine having two independent ignition systems, a timer, coil and battery for one set of plugs and a high-tension magneto for the other. The switch for the magneto is a plug which is moved in or pulled out. INFORMATION.

Elizabeth, N. J., Sept. 23.

With the true high-tension magneto the flow of the primary current is diverted by grounding it; that is, by a wire led from the primary post on the breaker box to the metal frame. The switch is incorporated in the circuit to close it when it is desired to stop the operation of the motor. The trouble is doubtless in the switch, which does not close the circuit as above explained. It should be a simple matter to remove the member, clean and adjust any loose parts. It would be well to inspect the connection to the terminal on the breaker box.

Make and Break Ignition.

(49)—What is the operation of a make and break system of ignition and how does it differ from the jump spark? Why is it that the jump spark is more used? CURIOSITY.

Peoria, Ill., Sept. 25.

The components of the make and break mechanism consist of a fixed and movable member, one suitably insulated from the cylinder of the engine and the other grounded, so as to complete a circuit when the moving part is in contact with the other part. Upon the hammer separating, a flame is created. With the jump spark system of ignition the electricity is forced to bridge an air space or gap, and because of the current jumping from the insulated electrode to the base or shell, is termed a jump spark. With the make and break system a coil is employed called a "hog" coil, which does not build up the current as does the induction coil because the resistance is slight, whereas with the spark plug considerable voltage is required.

The jump spark has succeeded the older form of ignition in automobile engines because with it the spark may be more perfectly synchronized; that is, made to occur at the proper instant and when the greatest efficiency is obtained from the burning of the mixture. With the make and break there is considerable wear of the contacting parts, some leak of compression and more or less difficulty in synchronizing the break with multi-cylinder engines. The make and break is used with single-cylinder marine engines with success.

The Kearns Motor Truck Company has been incorporated under the laws of Delaware with a capitalization of $100,000.

THE A B C OF MOTOR TRUCK IGNITION.

Part XIV---Outlining the Construction and Operation of the Splitdorf Magneto Which Provides Dual Ignition with One Set of Spark Plugs---How the Current Generated Is Transformed into High-Tension.

By C. P. Shattuck.

IN THE last installment the various types of magnetos utilized for ignition purposes were defined and reference was made to the instrument having a single winding on its armature and employing a transformer for building up the current generated. This type of magneto is termed a high-tension, although a low-tension current is obtained from the instrument itself, because the electricity generated is transformed into a high-tension current and distributed by magneto.

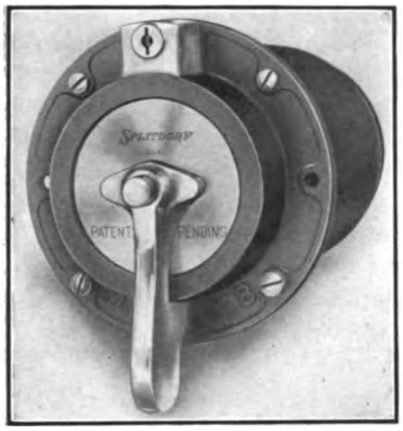


Fig. 71—Unit Switch and Coil.

It is not the purpose of the writer to compare the true high-tension with the transformer types. Each possesses advantages and there is a great difference of opinion between designers and engineers as to which is the better. Advocates of each system present lengthy arguments in support of their claims, but as both systems are in general use, it must be considered that both are entirely satisfactory.

Advantages of Transformer Types.

Since this discussion deals with a transformer system the advantages claimed for it will be presented. It is held by its advocates that the liability of internal short circuits is reduced when a single winding is employed on the armature and current of comparatively low-tension is generated therein; that better insulation can be provided when the transformer coil is made a separate installation, and that this increases condenser capacity. Another advantage held of the design is that dual ignition may be obtained, only one set of spark plugs being necessary. This simplifies matters in that one switch controls both the battery and magneto circuits and but one secondary wire is required for each cylinder.

Although the magneto may be used for starting, the batteries are supplied for emergency use, making starting easier when the motor is cold or when conditions are not favorable to quick turning of the hand crank. With some systems provision is made for starting the motor from the seat by pushing a button, the operation producing a spark in a cylinder by interrupting the primary circuit leading from the cells. This is similar to the result obtained with the battery, coil and commutator system of ignition, where the primary circuit is closed by making contact between the roller and contact block of the timer. Of course, with either installation, there must be gas in the cylinder and the piston must be about to begin the firing stroke.

Although the principles of the single-wound magnetos are practically the same today as when first fitted to the automobile engine, the manufacturer has made many refinements, these including a more compact instrument and better enclosure of the working parts so that moisture and foreign elements do not affect their efficiency. More attention is paid to the construction of the high-tension wire terminals, consequently they are easily removed and replaced; in fact, many former minor troubles have been eliminated by refinements in details.

Single-Wound Armature.

A magneto having a single-wound armature and providing dual ignition is the Splitdorf, made by the Splitdorf Electrical Company, Newark, N. J., the product of which is well known to the automobile industry and owner. The company manufactures a variety of designs to meet the requirements of different in-

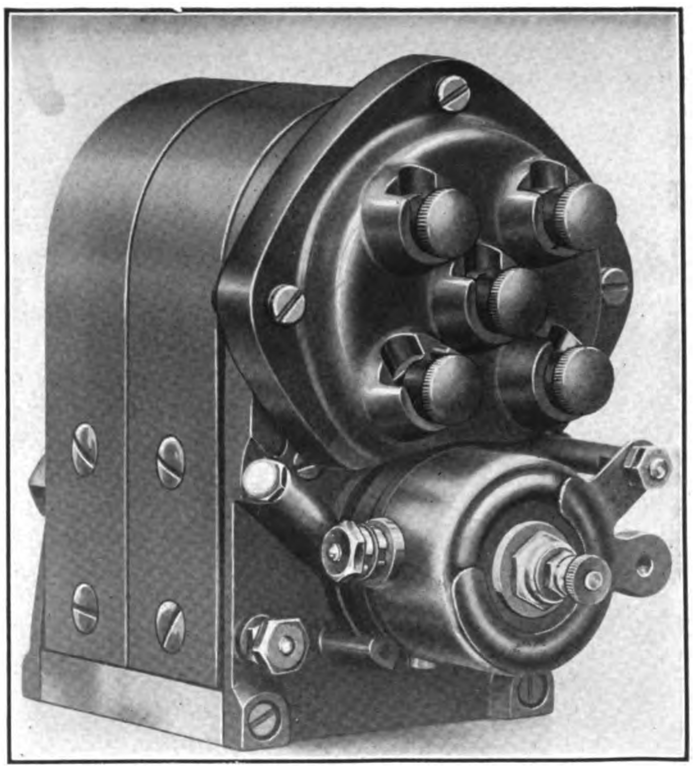

Fig. 72—Model A Splitdorf Magneto, Having Single Winding on Armature, Which May Be Driven in Either Direction.

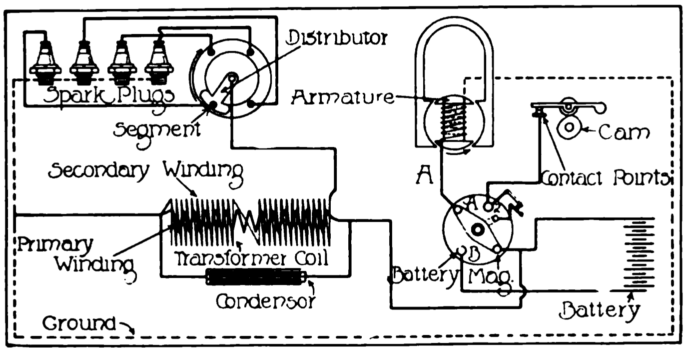

Fig. 73—Diagram Illustrating Principles of Splitdorf Magneto System.

stallations, and in keeping with its policy to improve on past models, has produced a new type known as model A, 1914, which is shown at Fig. 72. Among the features of the new magneto are: All breaker box parts are interchangable throughout, easily demountable and all working parts well protected from moisture.

The complete system includes the magneto, a TSA transformer and batteries. The last named may be any standard six-volt storage battery or dry cells. The switch and transformer coil are a unit, very neat and compact, as will be noted by the illustration at Fig. 71. The transformer is mounted on the base of the switch, the face of which is designed to be mounted on the dash, where it may be controlled by the hand or the foot. The transformer is enclosed in a light water proof case extending through the dash, and being mounted on the base of the switch the connecting leads from the switch contacts to the transformer are very short. The terminal wires from the interior of the transformer are brought to an enclosed casing at the rear, to which point the battery and magneto leads are brought and connected to their respective terminals. On the face of the switch is an ignition button, used for starting the motor on the battery only.

Paths of Currents.

A longitudinal and end view of the magneto is shown at Fig. 76, and the various components are plainly lettered. The armature, which is shown sepately at Fig. 74, has a single winding of coarse wire; is supported by annular bal} bearings as indicated at Fig. 76, and revolves in the magnetic field produced by the permanent horseshoe magnets. One end of the armature winding is grounded, the other is coupled to a conducting member that passes through the contact breaker end of the armature, but is insulated from it.

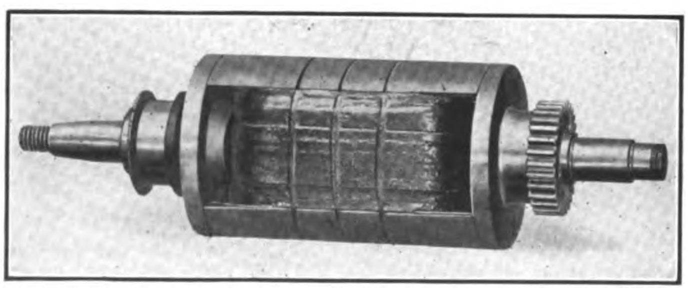

Fig. 74—Splitdorf Armature, Including Driving Gear and Tapered Shaft.

Brushes are mounted in the contact maker cover and bear against the conducting member in such manner as to collect the primary current generated in the armature winding, which is led to the transformer coil.

The timer or circuit breaker parts are shown at the right in Fig. 76, and include a cam which is mounted on the armature shaft. In the design illustrated, which is a four-cylinder unit, the cam raises a contact lever twice every revolution of the armature shaft, interrupting or breaking the platinum contact points apart at those intervals when the armature is in the position of maximum current production, or, in other words, when the electricity generated is at its greatest value. It is at this point of interruption that the high-tension current is induced in the transformer coil and led to the spark plugs.

Operation of Circuit Breaker.

The circuit breaker mechanism is depicted at Fig. 75, but without the cam. It will be noted that the contact lever is pivotally mounted and normally is held against the fixed or lower contact screw by a spring. When the cam comes in contact with the lever mechanism, the two platinum points separate, break-

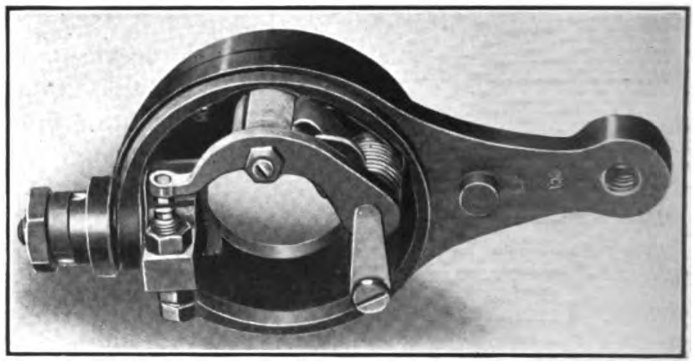

Fig. 75—Circuit Breaker of Splitdorf Magneto Removed to Show Construction and Operation of Platinum Contact Points.

ing the primary circuit. The lower or fixed contact point is made adjustable to provide the proper break, and is insulated from the other parts.

The distributor is mounted inside the magnets, above the armature, and is driven from the armature shaft by gearing. The last named member carries a gear having half as many teeth as the distributor gear, as it makes two revolutions to one of the larger member, as previously explained. The distributor comprises a plate of insulating material carrying a contact segment. The current from the high-tension lead of the transformer coil is supplied to the central brush or terminal of the distributor, which bears against the distributing segment, this in turn making contact with the brushes connecting with the secondary wires leading to the spark plugs.

Operation of Magneto.

The general principles involved in the Splitdorf magneto may be understood readily by a study of the diagram presented at Fig. 73, which shows the wiring and the relation of the various components of the ignition group to each other, although these are not depicted in the exact positions they occupy in actual ap-

plication. With the switch lever in the position shown and the platinum points of the circuit breaker making a connection, any electricity generated in the armature windings is short circuited and flows through a limited circuit formed by the wire A, the switch bar, then from the centre of this to the contact 2, thence to the contact points and back to the armature winding.

When the platinum points are separated by the action of the cam, the electricity flows through the connection A, through the switch bar to the contact at the other end, which leads to the primary coil, and, after passing through this and energizing the core, it returns by the way of the ground to the armature winding. Upon the platinum points making contact, the current from the armature is again short circuited and cannot pass through the transformer primary coil. The path of the high-tension current is followed easily.

Path of Battery Current.

If the position of the switch lever be reversed, so that it is in contact with terminals 2 and B, the battery current is interrupted by the platinum members. The path of the electricity is by the conductor leading from the battery to the terminal B, through the switch bar to the terminal 2, thence to the platinum contact points as long as these are in contact, and through the ground to the primary coil, from which it returns over the conductor leading from the extremity of the primary coil to the batteries. Upon the platinum points separating, a high-tension current is induced in the coil because of the sudden demagnetization of the primary coil core. At this moment the metal distributor segment is in contact with one of the brushes connecting with the spark plug, and a spark occurs in the cylinder.

It will be noted from the wiring plan of the magneto presented at Fig. 78 that the positive and negative wires from the battery are led to the transformer coil and that neither lead is grounded, differing from the battery, coil and timer system of ignition. It will also be seen that the high-tension current obtained from the transformer is led to the central brush or terminal of the distributor. The wiring plan is very simple.

Methods of Drive.

The Splitdorf four-cylinder magneto is driven at crankshaft speed and must be positively driven either by gearing or by an Oldham coupling, the latter being recommended by the maker because absolute setting and alignment are necessary with the first named method. Chain drive is possible, but should only be utilized where a positive drive is not easily obtained.

One of the features of the Splitdorf magneto is that it may be driven in either direction—clockwise or anti-clockwise. If it be desired to change from one direction to another the breaker box is displayed, the driven end of the armature shaft held firmly with a pair of pliers and a small nut removed. The cam, shown at B, Fig. 77, is retained by a Woodruff key and may be removed easily, turned over and replaced. It is advisable in replacing the nut to prick punch it so that it will not jar loose in service.

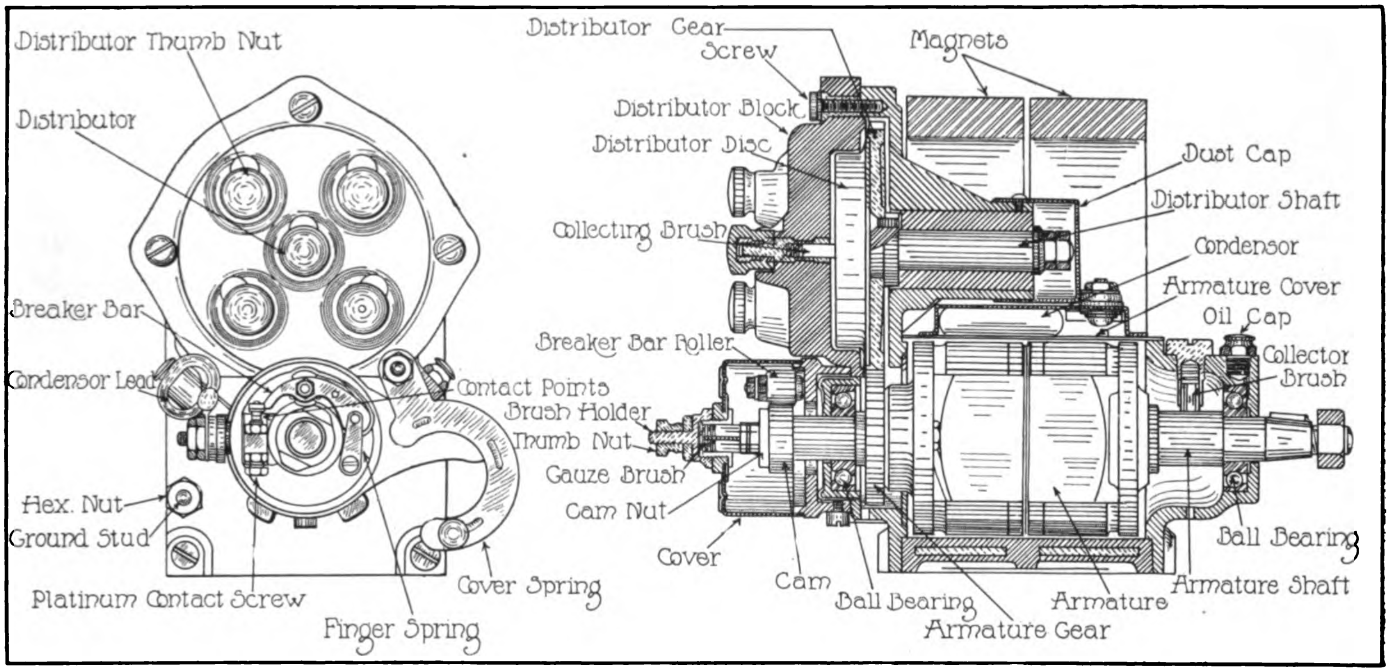

Fig. 76—Longitudinal and End View of Model A Splitdorf Magneto, Outlining Arrangement of Components.

Changing Direction of Drive.

Next displace the distributor block, also the insulated brush located at the driving end of the back plate of the magneto, taking out the four screws retaining it. By removing the back plate and sliding the armature backward, the gears will be moved out of mesh. In remeshing the gears the direction of rotation must be considered. If the instrument is to be driven left handed or anti-clockwise, looking at the driving end, the platinum points S shown at Fig. 77 A should begin to separate as the armature core leaves the pole piece, or when there is a space of about .0625 inch between these members, as indicated in the drawing. The segment should be just under the brush. The view at C shows a magneto driven clockwise or right handed,

and it will be seen that the armature occupies a different position relative to the pole piece than when the shaft was rotated in an anti-clockwise direction.

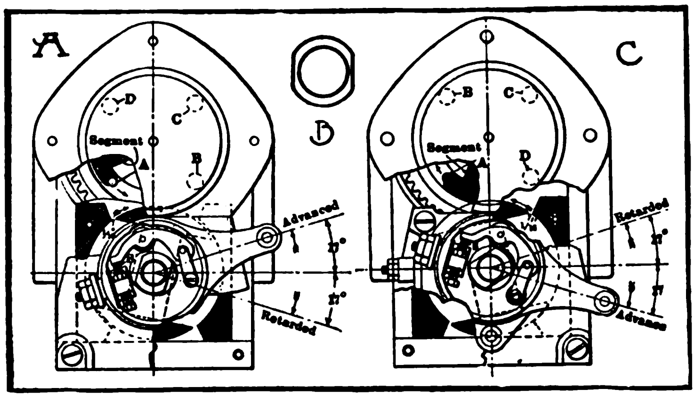

Fig. 77—Illustrating Anti-Clockwise and Clockwise Drive, and Proper Relation of Armature Core to Pole Piece When Changing Direction of Rotation: A, Anti-Clockwise; B, Removable Cam; C, Clockwise.

The model A Splitdorf is timed as follows: Place the instrument on its base and crank the motor until the piston of the first cylinder (that nearest the radiator) is at the top of the compression stroke or dead centre. This may be determined by passing a wire through the petcock or by observing the position of the crank throws of the crankshaft. The spark lever on the steering column is fully retarded and the linkage is connected to the advance lever on the breaker box. If the magneto shaft rotates in a clockwise direction, looking at the driving end, the lever should be placed in its maximum top position as shown at C, Fig. 77. If the shaft revolves anti-clockwise the lever must be at the bottom or as indicated at A. Having ascertained the direction of rotation the armature shaft is revolved until the breaker cam comes in contact with the roller of the breaker bar and the points just begin to separate. The connection between the driving member and armature shaft is then made. It is important to observe that the position of the piston in the cylinder is not changed during this work.

Timing the Magneto.

To connect the secondary wires it is only necessary to ascertain the position of the distributor arm, and its direction of rotation. It should be borne in mind that it rotates opposite to that of the armature shaft. For example: If the shaft revolves to the right the distributor arm will rotate to the left, and vice versa. With the shaft rotating as shown at Fig. 77 C, and assuming that the segment is making contact at A, this terminal is connected to the first cylinder of the motor. The remaining contacts to be made will be B, C and D, but the firing order of the engine must be considered. It will either be 1, 3, 4, 2 or 1, 2, 4, 3, and in fitting the secondary wires to the distributor terminals this firing order must be observed.

In starting on the battery the spark lever is fully retarded and the switch lever thrown to the battery side. If it be desired to start on the magneto the spark should be advanced about one-half or two-thirds way. The best results are obtained from the instrument when the break of the platinum contact points is not more than .03125 inch. The maximum gap of the spark plugs to be observed is the same.

(To Be Continued.)

Ed. Note—The next installment will deal with the construction, operation and installation of true high-tension magnetos.

PACKAGE DELIVERY ECONOMY.

Willys Utility Wagon Increases Business 77 Per Cent. at Two-Thirds the Cost.

The use for two months of a Willys Utility wagon of 1500 pounds capacity by a department store in the Middle West has shown decidedly interesting and economical results. The superintendent of delivery is authority for the statement that the increase in business is 77 per cent. with a saving of 33 per cent. in operation and maintenance cost when three horse wagons were used for this work.

During the period stated the wagon delivered 9246 packages a month as against 5328 packages for the animal wagons, and the cost of delivery was reduced from 3.5 to 2.30 cents a package. In making comparison the packages delivered were rated at a dollar each and the profit placed at 10 per cent. on each. On this basis the net income of the store was increased $391.80 a month, and a saving of $110.95 a month, or a total of $1331.40 a year, made in the operation and upkeep expense of the store's delivery system. The saving that appears practical is not far from the cost of the machine.

The sale of five 1500-pound KisselKar delivery wagons to L. S. Donaldson of Minneapolis, Minn., replacing five other machines, gives that merchant a fleet of 10 KisselKar machines. The first KisselKar was bought June 15, 1912, and in July of this year two more were purchased. In August two additional wagons were delivered, and in September five. Five of the largest department stores of Minneapolis and St. Paul are now using KisselKar delivery wagons exclusively.

"ELECTRIC VEHICLES."

An Analysis of the Utilities and the Possibilities of a Means of Transportation That Is Being Carefully and Scientifically Promoted in America.

By Arthur Williams, President of the Electric Vehicle Association of America.

THE electric motor car, as an adjunct of modern life, has come to stay, because it has a distinct and proven field of usefulness. Today its advocates firmly believe that, while gasoline vehicles may be better suited to touring and long-distance hauling, electrics are their superiors for delivery service, short hauling and most city demands. Within the last two years thousands of converts have been won over to the electric automobile and that industry has grown with remarkable swiftness.

Some 30,000 such vehicles are now in use throughout the United States. Of this total, about 10,000 were manufactured during the past year; 6000 of these being pleasure cars and the other 4000 commercial wagons. About two-thirds of all the electrics operated in this country are pleasure vehicles, the remaining third being designed for business purposes. Oddly enough, perhaps 80 per cent. of the latter are in use east of the Alleghanies; while by far the heaviest demand for pleasure cars comes from the Middle West. This, of course, speaks well for them, since it proves that, unlike the prophet in the proverb, they are honored in their home territory, being most favored in regions where they are manufactured and where, consequently, they are best known. In New York City only about 400 electric pleasure cars are registered, but Chicago is on record as possessing about 2200. On the other hand, New York uses nearly 1700 electric trucks and delivery wagons, as against Chicago's 460.

Everywhere current driven automobiles are gaining popularity. In New York between July 1, 1911, and July 1, 1912, their number grew 45 per cent.; while an authority on electrical affairs estimates that in Chicago this method of trucking has increased 400 per cent. during the last two years. At St. Louis, for the first six months of 1912, one central station reported a gain of almost 37 per cent. in income from charging cars. Such recent and rapid strides into public favor are due to several causes, among them: Improvement in the cars themselves, decrease in the cost of current, better charging facilities and co-operation among all those interested in the progress of electric vehicles.

Most fundamental of all these causes are changes for the better which have been wrought in the cars. It is a well known fact that early models—those of the '90's—though by no means as impracticable as their detractors represented them, were often clumsy, complex of mechanism and equipped with inadequate batteries. Today, however, the electric is the simplest to operate of all motor cars. Years of experimentation have developed the capacity of batteries, so that the average distance which a pleasure vehicle can now travel upon a single charge has been increased to 65 miles, while a maximum of 100 miles, under favorable conditions, is boasted for not a few.

Then, too, the cost of current has grown steadily less, while that of gasoline is constantly rising. Ten years ago the price of current for charging averaged about 23 cents a kilowatt-hour throughout the United States; but today it sells, on the average, for about five cents a kilowatt-hour, with a reduction to three cents for large consumers. Meanwhile, the price of gasoline has soared. Though a decade ago it was only 10 cents a gallon, the same amount at present costs about 24 cents, and demand will continue to make it grow dearer. Current, on the other hand, since it can be generated in unlimited quantities and since this particular form of supply constitutes an "off-peak load", will tend to fall still lower in cost.

Years ago, lack of convenient charging stations was an annoying hindrance in the way of using electric vehicles. But, recently, current replenishing depots have multiplied in cities and on routes between important towns, so that it is now an easy matter for a car to be recharged. Lists of such stations have also been compiled and furnished to owners of electrics.

But among causes for the increased popularity of current fed automobiles, perhaps the most far-reaching is co-operation between car manufacturers, accessory makers and central station authorities. Such a spirit of mutual helpfulness rather than of rivalry is, of course, unusual in business and has been brought about, in this instance, almost wholly through efforts of the Electric Vehicle Association of America. The aims and accomplishments of this organization will be described later, but here it is interesting to call attention to the fact that, though the association has been in existence only two years, this period is coextensive with that of greatest prosperity in the electric vehicle industry.

Before turning aside from the consideration of the cars themselves, it may be best to put the question: What are their advantages? In other words, what qualifications for city use do they possess which lead a merchant to abandon, in their favor, his horse drawn vehicles? The answer, in three words, is: Economy, safety and reliability.

In the matter of economy, several facts must be taken into account. In the first place, one electric truck or delivery wagon—owing to its greater rapidity—can do the work of several horse drawn vehicles. The average life of a horse, pulling heavy loads over city streets, is four years, while that of current fed trucks is twice—sometimes three times—as long. Besides this

the electric truck is proof against the diseases to which horseflesh is heir, and which killed 19,163 animals in New York City between October, 1911, and October, 1912. Then, too, it is so simple in mechanism that an ordinary teamster can learn to drive it. Altogether it has been estimated that current driven delivery is from 10 to 25 per cent. cheaper than hauling by horse.

The advantages of reduced fire risk involved in the use of electric vehicles must be apparent. Besides protecting the public by eliminating the source of many sudden blazes, absence of inflammable materials in these cars admits them to docks, piers and terminals from which gasoline machines are often excluded. Within the last few months the New England Casualty Company—after careful study of the subject—arranged to grant a large reduction of rates to electric vehicles. This decrease will bring their insurance 20 per cent. below prevailing rates for gasoline vehicles.

Ease of operation in crowded streets is another important advantage possessed by the electric, to which may be added special suitability for many stops, starts and waits, such as are often necessary in delivery service.

The popularity of electric commercial vehicles is attested by a long list of well known business houses which employ them. A few among these are: The American Express Company, which uses 300 such cars; the Adams Express Company, with 250; the Ward Bread Company, with 200; the New York Edison Company, which owns 105; Gimbel Bros., New York, with its fleet of 85; the Case & Martin Company of Chicago, which operates 100; John Wanamaker & Co., New York, with its 94; the United States government, which owns 51; the Anheuser-Busch Company of St. Louis, with 57; B. Altman & Co., with 70; Marshall Field & Co., with 18; the Fair, Chicago, with 34; Abraham & Straus, Brooklyn, which uses 20; Frederick Loeser & Co., also of Brooklyn, which possesses 26, and a host of other equally important firms which operate fleets varying in size from 10 up to 70. The examples mentioned serve to show that wherever electric commercial vehicles are adopted, they are used in groups. This is generally brought about through the success of a trial installation of one or two cars.

Lest the reader should think that the electric motor truck is an altogether recent development, it may be worth while to cite the case of one such machine—owned by the Bergdoll Brewing Company—which began its career in 1903 and is still running through the streets of Philadelphia. During four of these years of active service it was not out of commission a single day. Another veteran is the "Mary Ann," the original motor dray of the New York Central Brewing Company, which, built in the late 90's, still goes out on business in all weathers, and which costs her owners less than $100 a year for repairs. These old timers, holding their own after a decade's use, form a strong argument in favor of current driven vehicles, one which is often overlooked on account of a popular notion that all early models were delusions and snares.

There is no doubt that the Electric Vehicle Association of America has been the moving force in waking the electric automobile industry from its lethargy. This organization's history is brief, for it was formed only in the fall of 1910. At that time, current propelled cars suffered from lack of concentrated effort to push them into public notice. Their makers found the cost of production high, owing to comparatively small sales; storage battery concerns had, accordingly, an extremely limited market for their output, and central station managers, seeing but little demand for current for charging, kept the price of such supply at discouragingly high figures. It was to change these conditions that delegates of these three separate and yet interdependent interests, formed the Electric Vehicle Association of America. Its initial membership of 29 has grown to more than 350; that number at present representing a combined capital account of over $500,000,000.

The keynote of the organization's plan was co-operation, and this has been followed consistently. A joint advertising campaign has been carried out in all parts of the country, any asserted advantages of one make over another having been ignored, but every effort being made to bring to the notice of the general public the good points of electric motor cars. Besides this, arrangements have been effected within the association for interchange of information and ideas, and for the study of pertinent problems.

As results of these activities, the organization points, first of all, to the recent remarkable prosperity of the electric automobile industry. And it is an undeniable fact that this "boom" has been felt since the Electric Vehicle Association of America began its efforts. Contributing causes to this success may be found in the multiplication of charging stations—brought about through the association—and in the standardizing of the charging plug—also recommended by the association. In addition, a uniform sign has been adopted for use throughout the country to indicate battery replenishing stations, and such a sign is at present being manufactured.

The fact that this sign is to be alike throughout the country implies that electric vehicles are not by any means restricted to urban service and that they do travel from one city to another. This brings in the question of good roads; a question in which the Electric Vehicle Association of America takes active interest. Whether in town or country a smooth road bed results in less wear and tear on an automobile, to say nothing of its occupants, and, for this reason, the association has considered methods of preparing and maintaining good street surfaces, together with the manner in which various sizes and styles of tire affect road beds.

What the organization has done in the past, however, is only a small part of what it hopes to accomplish in the future. It intends to carry the principle of co-operation still further, since it is through this practise that success has already come. Among other ef-

forts, it will give attention to further standardization of various machine parts, including styles of batteries, lamp bases and tire equipment. Interchangeableness of parts is a more important feature of the electric automobile than of the gasoline, and adoption of such improvements as seem practicable will undoubtedly increase still further the popularity of electrics.

The future of the current fed vehicle is assured. It has won its way—on merit—into public confidence, and coming years are bound to see a steady growth in its favor. It will commend itself more and more for city use on account of its ease of operation, simplicity of mechanism and reliability. Already, authorities are predicting an output of some 15,000 electric motor cars during 1913, an increase of 50 per cent. over the records for 1912.

In our great cities the hauling of goods will be done to a large and larger extent by electric trucks, because these vehicles can thread their way through crowded thoroughfares, and because, owing to their non-inflammable propelling force, no pier or terminal is closed to them. How great an assistance this will be in solving traffic problems, only those who have studied them can know. It may lead to the hauling of heavy goods through wholesale districts at night, thereby ridding our overburdened avenues of slow moving drays by day, and facilitating the rapid transit of wares to railways and steamships.

The trackless hauling in this country has been estimated at 16 times as much as that done by railways, and of this 80 per cent. is carried on in cities. Now if electric propulsion were adopted for this work, it could be performed more quickly, safely and economically than by horse power and this ought to result in reducing prices of many commodities.

The electric pleasure car will gain an increasing number of adherents on account of the ease with which it may be driven, the low cost of its maintainance, its dependability in all weathers, and the simple requirements for its garaging. It, together with its companion, the current driven truck, will help to gain for the community greater expedition and economy in business and increased comfort and enjoyment in everyday living, as well as cleaner streets, safer highways and reduced fire risks.

EVOLUTION IN DELIVERY.

Requirements by the Public Necessitate Improved Store Transportation.

That there has been an evolution in delivery in practically every form of commerce and industry, which has not been keenly realized because of its being an every day condition, is pointed out by John M. Lansden, second vice president of the General Motors Truck Company, who emphasizes some facts that may be obvious upon reflection, yet which have not received the serious consideration they should. In this connection Mr. Lansden says:

The solution of what appears to be one of the largest problems to be overcome by the men who are working out the marvelous merchandising systems of American cities, seems to lie in the development of the electric commercial vehicle.

Although electric commercial vehicles have been used for almost two decades, it was not until a half-dozen years or so ago that they began to take an important place in our present day scheme of haulage and delivery. Today the electric truck is making the most extraordinary advances in its field—city and suburban use.

Last year the number of electric commercial cars used in some of our metropolitan cities increased considerably over 50 per cent. And a most significant fact is that a large percentage of the machines were sold on reorders. The development of the retail trade in the larger American cities during the past decade has been a commercial wonder to the rest of the world. And it had no experience to go on—no precedent to follow. Improved merchandising methods brought a sudden and enormous increase of sales in all sorts of lines.

Department stores have had a big place in changing conditions, but every sort of retail and mercantile concern has been effected. The concentration of industries has been another factor in increasing the use of electric trucks.

Food, milk and produce supplies have been centred in the cities and all this has tended to multiply the necessity of adequate and efficient transportation methods. The manufacturer of supplies—as he may be called—the baker, the brewer, florist, soft drink maker—and the middleman, like the wholesale meat or provision dealer—have come to the same relation to their customers (the grocer, the drug store and the butcher shop) that the dealer has always occupied toward his customers. Meanwhile the buying public has demanded that its supplies be fresher than in less discriminating days, as well as greater in variety and better in quality.

So the wholesaler has had a new delivery problem to meet and like the retailer, it has been rapidly complicated by the constant widening of the territory in which business is transacted.

The horse has failed to meet the emergency. Being only flesh and blood, he has only flesh and blood endurance. He could make just so many miles a day at such a speed. He had to be given occasional rests. He had to be allowed a certain amount of sickness. And with the increasing strain, he not only could not cover the ground that had to be covered with the spreading out of our cities, but he became less reliable in the field which represented the utmost of his ability.

It was these weaknesses of the horse that gave the commercial vehicle its first start. And the inherent qualities of the electric truck have brought it into prominence as a substitute for the horse in city and suburban delivery work.

The electric truck is unusually easy to operate. Its care is exceedingly simple; and altogether it meets in an eminently satisfactory manner the new conditions of merchandising distribution in our rapidly growing American cities.

The annual meeting of the Electric Automobile Manufacturers' Association was held at Cleveland, Sept. 10, and in connection with the usual business officers were elected as follows: President, Louis E. Burr, Woods Motor Vehicle Company, Chicago, Ill.; vice president, R. G. Norton, Baker Motor Vehicle Company, Cleveland, O.; secretary and treasurer, F. H. Dodge, Ohio Electric Car Company, Toledo, O.; executive committee, G. D. Fairgrieve, Anderson Electric Car Company, Detroit, Mich.; H. H. Rice, Waverley Company, Indianapolis, Ind., and C. F. L. Fisher, Rauch & Lang Carriage Company, Cleveland, O.

The Phoenix Rapid Transit Company, Phoenix, Ariz., which operates a trolley system in that city, has decided to experiment with the motor passenger conveyance to determine its economy as compared with track roads. The company has purchased a three-ton KisselKar chassis and will install a 25-passenger body on it and operate it in the sections not now served. If this is a success other machines will be bought.

A second three-ton White truck, equipped with dumping body, has been placed in service by the W. F. Gilbert Company, a well known coal dealer of New Haven, Conn., the results with the first machine amply justifying the purchase of another.

STORAGE BATTERY CHARGING EQUIPMENT.

A Statement of the Needs for Varying Forms of Garages and Service Stations, with Reasonable Provision for Expansion and Meeting All Conditions of Use.

By R. E. Russell.

THE following article by R. E. Russell, an engineer nected with the rectifier sales department of the General Electric Company, Schenectady, N. Y., is of special interest to every person who is considering the installation of equipment for charging electric vehicle batteries. Mr. Russell has taken up a very broad subject and has briefly considered the essential detail of equipment that may be utilized for the private garage, the public service station and the department store garage, dealing with varying currents and voltages, and specifying the economies or advantages that may be obtained from differing apparatus under given conditions. He has also specified the needs for charging both lead-acid and alkali battery cells, emphasizing provision for attention peculiar to each type.

Mr. Russell's article refers to different forms of current supply and differentiates the equipment necessary with such conditions as are customarily met with, and he makes suggestions that will be found of material value to all who are engaged in the manufacture, distribution or use of electric machines. One of the material items of operating expense is the cost of current, and the purpose of the article is largely to advise what will give sufficient and efficient service at maximum economy.

In preparing this paper it has not been, by any means, the intention of the writer to engage in any discussion regarding the relative advantages of the lead-acid battery over the nickel-alkaline or vice versa, but when it comes to charging they must be handled somewhat differently to get maximum results, as to efficiency, simplicity and general good characteristics.

It is the purpose of the writer to recommend charging sets for any ordinary conditions that may exist. It is to be hoped, with the growth of the electric vehicle industry and with the present rate of central station progress, that the many conditions met with nowadays will in the near future be reduced to more practical limits.

Before taking up the various suggestions for charging let us first analyze the conditions as regards battery, supply circuit and number of vehicles.

There are, as already stated, two general types of battery:

1—Lead-acid.
2—Nickel-alkaline.

The supply circuits met with ordinarily (if there is any supply) are:

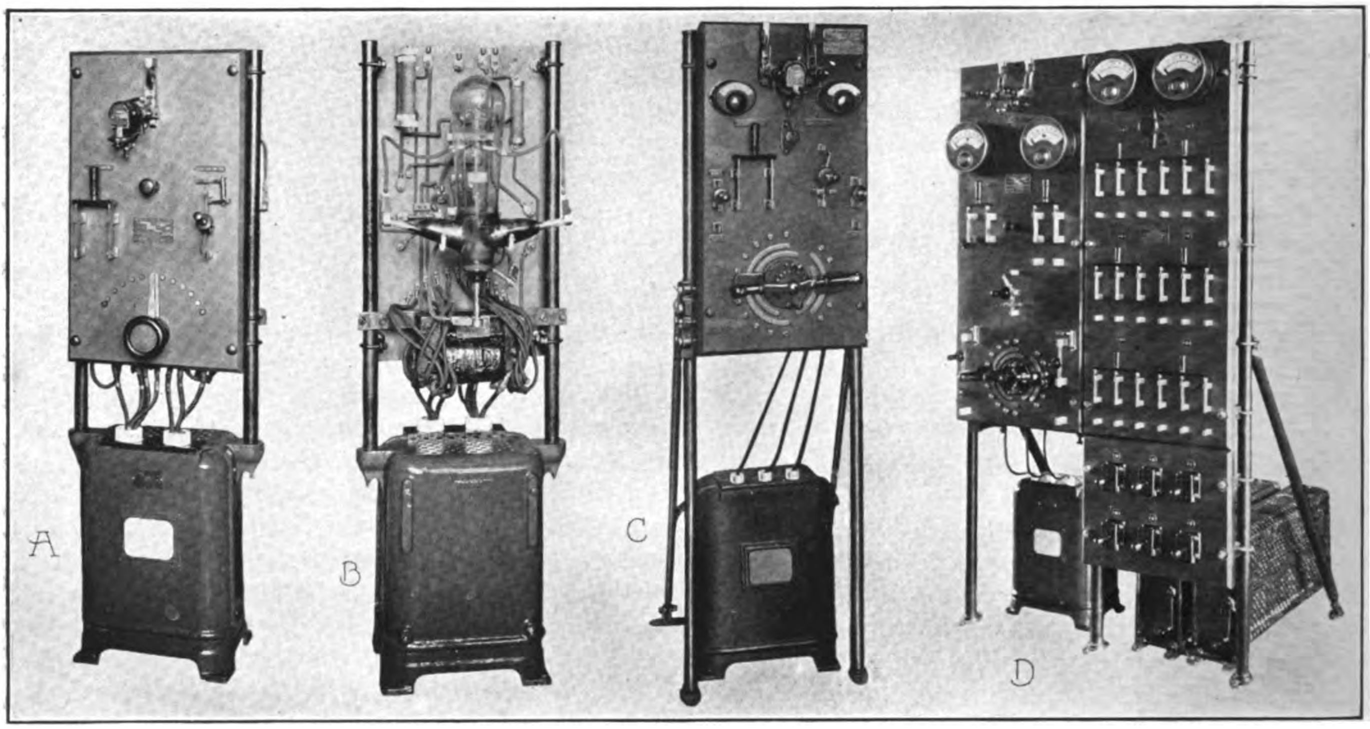
Alternating Current—One hundred and ten and 220 volts or any other voltages that may be required can usually be obtained. The question of number of phases or frequency need not be considered, except that any apparatus purchased must conform to them.

Direct Current—One hundred and ten to 125 and 220 to 250 volts; 220 to 250 volts only, and 500 to 600 volts only.

Probably the hardest part of a charging recommendation is the determination of the capacity of the charging equipment. If in a private garage where only one or two cars are to be charged it is simple. But the conditions are quite different in a public garage, where the batteries may vary from a light 24-cell runabout battery with a charging rate of 19 amperes to a five-ton truck equipped with an Edison A-12 battery requiring 90 amperes normal with a possible boosting current of 450 amperes. To say the least, some study must be given to the conditions.

In order to get some general basis the following classifications are made:

(a) The private garage, usually limited to one or two vehicles.
(b) The average public garage, which starts in on a small basis and yet should be able to charge any transient car which comes in and still take care of regular customers. The cars for the most part will be pleasure electrics, but there may be some commercial cars.
(c) The large public garage, handling as many as 200



Mercury Arc Rectifiers for Garage Equipment: A, Runabout Type, Front View; B, Runabout Type, Rear View; C, Single-Phase Panel, Front View; D, Single-Phase Panel and Garage Outfit, Equipped with Sub-Base.

electric pleasure vehicles and trucks.

(d) The department store or express company garage, caring for commercial vehicles only.

In selecting charging apparatus to meet the various conditions enumerated, the writer has endeavored to keep in mind:

That the efficiency must be high without adding complications; the first cost as low as is consistent with good design; that the apparatus should be well made to keep down the maintenance cost; and that the floor space be as small as possible without sacrificing convenience.

The possible future growth of the garage will make more or larger apparatus and circuits necessary, and should be carefully considered. To my mind simplicity in design of a charging layout is of the utmost importance, particularly in the smaller garages where help is frequently changing and a new man must be quickly "broken in."

The devices which may be used for battery charging are as follows:

For Direct Current Circuits—Charging rheostats and distributing panels, motor generator sets and control panels where the supply voltage is 220 volts or over, boosters or dynamotors.

For Alternating Current Circuits—Mercury arc rectifiers, rotary converters, motor generator sets (A. C. to D. C.), mechanical or synchronous rectifiers.

If central station service is available it is not recommended that a garage generate its own current for charging by means of a gasoline or steam engine and generator, as it is very seldom, and then only under the most favorable conditions, that the private or isolated plant can compete in cost of producing current and in reliability of service with the central station.

Where no central station service is available, as in the case of some summer resort hotels and rural residences, the convenience resulting from providing charging facilities practically amounts to a necessity. In such cases there is frequently installed a small 115 to 125-volt generating set, usually gasoline engine driven, of sufficient capacity to furnish lights and some power for the buildings and grounds. In such installations the factors that make for economy in up-keep and attendance and for the perfect voltage regulation required for high class illumination assure a reliability and dependability that is absolutely necessary for battery charging at such places. The combination of an engine and a generator, neither of which is designed or built for operation with the other, is usually in the long run an unsatisfactory solution of this problem. The increased efficiency and reliability of an isolated generating plant, built specifically for lighting purposes, is well worth the extra cost of such apparatus. Such a set would be equally well adapted to battery charging.

It always pays to buy a good motor generator set, as the higher efficiency, lower cost of repairs and longer life will amply repay the slight difference in first cost.

A rotary convertor with a regulating transformer, or preferably an induction regulator in the primary circuit of each rotary will make a very efficient equipment to change from alternating to direct current for very large garages where at least 75 per cent. of full load can be used at one time while the set is running in order that it may be operated at high efficiency.

At the present time there seems to be no satisfactory mechanical rectifier which will deliver enough current to charge even a single electric vehicle battery. So many inventors are working on various designs of mechanical or synchronous commutator rectifiers that it seems quite possible that we may expect some results before long. Consequently it has been listed above. There is without doubt a demand for a high capacity, reliable and inexpensive rectifier for charging large vehicle batteries.

Now to make suggestions for the various conditions already mentioned:

The Private Garage.

One Hundred and Ten to 125 Volts D. C.—For the private garage having 110-125 volts D. C., a small panel with suitable means for mounting it on a wall and equipped with line switch, fuses, preferably ammeter and voltmeter, and a battery charging rheostat for mounting on the wall beside the panel, makes a very satisfactory equipment. If there are two cars to be charged the panel should be equipped with two circuit switches and an extra rheostat added.

Two Hundred and Twenty to 250 Volts D. C.—For the private garage having only 220-250 volts D. C. (which is very rare), a large battery charging rheostat may be used, but the cost of a five-hour charge at 30 amperes would be about $1.65 at five cents a kilowatt-hour. If a motor generator set were installed the cost of charging the same battery (assuming 30 cells lead) would be about 75 cents, showing a saving in cost of charging of 90 cents. Even though the battery were charged on an average of only once a week the annual saving would be about $40, making a slight allowance for oil and brushes.

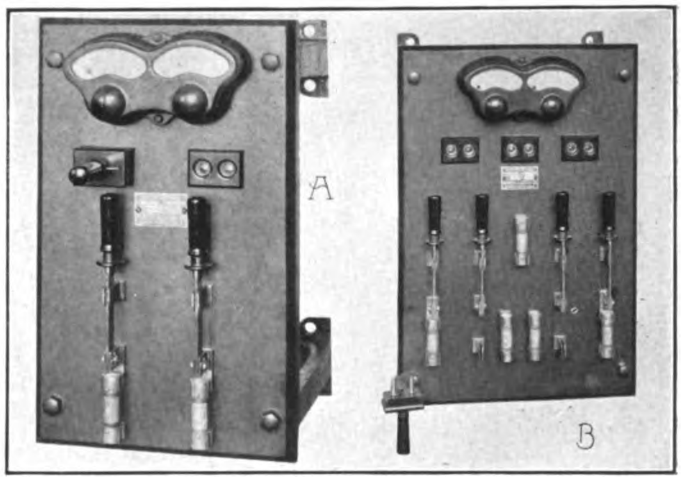
If a higher voltage battery were charged, a 44-cell for instance, and charging done very infrequently, the most economical and simplest equipment would be a charging rheostat and small panel with switch, instruments, etc.

Five Hundred to 600 Volts D. C.—If it can be avoided 500-600 volts should not be recommended for the private garage, and if there is a lower voltage available it should be selected, even though it may be alternating. If there is no alternative a small motor generator set should be installed. The motor should, of course, be designed for the line voltage and large enough to drive the generator at full load. The generator should be designed to deliver 50-125 volts, depending on the maximum voltage of the battery. For a 30-cell lead battery the generator should have a range of from 60 to 80 volts, and if the charging rate is 25 amperes the capacity of the generator should be about two kilowatts.

A control panel should also be installed. On it should be mounted a field rheostat for the generator, a starting rheostat for the motor, ammeter, voltmeter, 500-volt line switch, and an overload and reverse current circuit breaker. If there are two batteries to be charged at once two circuits should be arranged on the control panel and a rheostat should be connected in series with each charging circuit. In this case a larger motor generator set should, of course, be installed.

Alternating Current—For the private garage having alternating current, the mercury arc rectifier has demonstrated itself during nearly 10 years of actual service to be a very important accessory to the electric pleasure vehicle. Since their introduction they have been in constantly increasing demand, particularly in private garages. The reason for this demand is their extreme simplicity, high efficiency, the absence of moving parts—requiring oil and grease—and lack of vibration, making a special foundation unnecessary. The rectifier is also the cheapest reliable device for electric automobile battery charging that can be bought. The rectifier generally used in public and in some private garages is known as the Standard type; and that used in private garages is known as the Runabout type. The Runabout type on account of its extreme simplicity is recommended for charging batteries in private garages, and is particularly suitable for charging Edison batteries. A rectifier of 30 amperes capacity is plenty large enough to charge the average electric pleasure car, but if Edison A-6 batteries are used a rectifier of 50 amperes capacity and of the Runabout type should be used. For larger batteries two 40 or 50-ampere rectifiers can be connected in parallel by adding two reactances, and will make a very simple high capacity set.

Rectifiers for Edison Batteries—The Runabout type rectifier has been recently demonstrated to be particularly satisfactory in charging Edison batteries, especially of the A-4 and A-6 types, which have a normal charging rate of 30 and 50 amperes, respectively. To charge an A-4 Edison battery with this



Private Garage Type Battery Charging Panel: A, Single-Circuit; B, Two-Circuit, for Wall Mounting.

rectifier it has been found desirable to equip it with a 40-ampere tube, so that a charging rate may be started at, say, 35 to 38 amperes. The rectifier will maintain a rate of between 30 and 35 or 38 amperes throughout the greater part of the charge provided the line voltage holds fairly constant and does not droop toward the end of the charge. In a recent test this type of rectifier was connected to 64 cells of A-4 Edison battery and charged them for seven hours. At the start of the charge the direct current reading was 38 amperes; in one hour, 35 amperes; in four hours, 34 amperes; in five hours, 33 amperes; in six hours, 32 amperes; in seven hours, 30 amperes. Throughout the charge the efficiency averaged 77.5 per cent. As the discharge voltage averages considerably higher when the Edison battery is charged at full normal current or over, this test demonstrates the particular suitability of the Runabout type rectifier for this service. When charging an Edison A-6 battery a 50-ampere Runabout type rectifier should be used and the charge started at 50 amperes, and the normal rate should hold up in about the same manner as that outlined above.

Tube Life—Years ago some prospective purchasers suggested that the glass tube which contains the mercury arc on a rectifier would not last. Many of these purchasers of rectifiers are still using them with the original tube, doing the same work which it did over five years ago. It is found that the question of cost of tube replacement is almost negligible, especially when it is considered that the manufacturers guarantee them for a substantial life, and also considering the saving in cost in operating the rectifier in comparison with other charging devices for alternating current.

Home Charging—Probably every electric automobile manufacturer prefers that every pleasure vehicle he sells should be charged in the private garage at home. This is no reflection on the public garage, but is because the owner of the car always has it where he or she can use it at a second's notice; can save the current wasted between home and the public garage; and can, no doubt, save money by putting in a little time charg-

ing it himself (or herself). Some men and women take a certain satisfaction in running their own rectifier and charging their own car. The public garage will have plenty to do by arranging for monthly battery inspections, repairs, painting, etc., besides taking care of those who have an electric with no private garage.

The Public Garage.

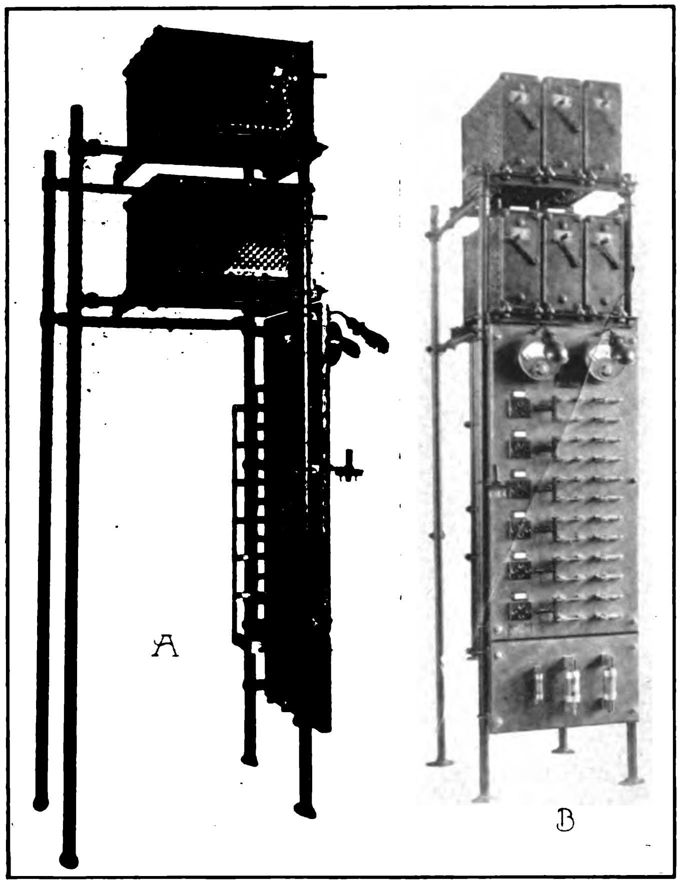
Alternating Current—In the public garage starting on a small scale a single 30, 40 or 50-ampere rectifier, with a wide range of D. C. voltage (30 to 120 volts), will take care of one or two regular customers and a transient car now and then. The 40-ampere size would be the best unless the regular cars require a high charging rate.

The objection to a motor generator set in a small garage, caring for from three to five cars, is that only very seldom can all the cars be charged at one time. A motor generator set should be used at nearly full load to be operated profitably, whereas a mercury arc rectifier will operate as efficiently at one-half current as at full load.

For the garage starting on a small basis the following equipment is suggested for installation as the business grows. It is assumed that the charging rate of each battery will average about 25 amperes.

At start, with one or two cars:

One 30-ampere, 30-100-volt, Standard type mercury arc rectifier.



Six-Circuit 110-Volt Standard Battery Charging Panel, Two-Wire, 360-Ampere Maximum: A, Side View, Showing Standard and Resistance; B, Front View.

On adding one or two cars, add:

One more rectifier, same type.

On doubling the number of cars, add:

One 40-ampere, 230-volt D. C. rectifier, with the charging circuits arranged in series-multiple. This makes a very efficient arrangement and rectifiers are often built with this arrangement.

If there is immediate prospect of a large increase in business, or if large Edison batteries are to be charged to any extent and other batteries are likely to vary in size and in charging current or for any other reason series charging is objectionable, the following equipment is suggested and should be used in place of the 40-ampere rectifier mentioned, retaining the two 30-ampere rectifiers, as they will be of value as explained later:

One motor generator set, consisting of a 15 or 20 kilowatt D. C. generator, 110 to 125 volts, (2.5 or three kilowatt capacity should be allowed for each of the lead batteries to be charged at one time. Edison batteries will require more, depending upon the number of plates and boosting charge required,) direct connected to a suitable size A. C. motor of the voltage and phase of the alternating circuit.

One motor generator control panel on which should be mounted a voltmeter, ammeter, line switch, generator field rheostat, starting compensator for motor and an overload and reverse current circuit breaker.

One distributing panel (or more, depending on the number of batteries to be charged at a time), each designed for six charging circuits. On each panel should be mounted an ammeter, voltmeter and means for connecting each to each charging circuit. For each charging circuit there should be mounted on the panel a double-pole switch with fuses to protect the circuits. It is also advisable, if more than one panel is used, to have fuses of ample capacity in the main line going to each panel.

Six battery charging rheostats (or more if required) which will have sufficient resistance and carrying capacity for the batteries to be charged.

With such an equipment it should be possible to garage from 20 to 30 ordinary pleasure vehicles, as very seldom will it be necessary to charge more than one-half of all the cars garaged at the same time if the charge is completed every time a battery is connected, which should be done for the good of the battery if for no other reason.

In selecting rheostats for battery circuits care should be used to get them with large enough resistance and enough carrying capacity. For ruggedness and ability to stand overloads cast grids make up the best rheostats, if they are strongly assembled and insulated with good heat-resisting material such as mica. Manufacturers of rheostats will recommend the types, resistance and proper carrying capacity of rheostats to use if they are supplied with the name plate rating of the batteries, the number of cells and the voltage to be used in charging.

The rheostats should be mounted on top of the distributing panel with which they are to be used. If they are of exceedingly large capacity and too heavy to mount at the top of the panels they should be mounted as near as possible to the panel with which they belong so that the ammeter can be seen while the rheostat is being adjusted. If the rheostats are mounted above the panels they may be adjusted by means of a special hook on a short pole.

After installation each panel should be numbered and each circuit lettered. The charging circuits should be wired from the panels through a rheostat in each circuit to outlets at convenient parts of the garage. In a garage having large floor space some of the outlets should be placed on the walls and others on the ceiling away from the walls. For those on the ceiling one end of a cord should be attached to the charging cable and the other end to a spring device, like a shade roller, so that when the cable and plugs are not in use they will be pulled up out of the way. Each outlet should be numbered and lettered to correspond with the panel and circuit to which it is connected.

On the card (in the card index) carrying the usual charging record of a car, owner's name, etc., should be one or more circuit numbers corresponding to circuits to which the car may be connected. It is, of course, not necessary, although preferable that a car be always connected to the same circuit, but to get proper results it should be connected to a circuit having a rheostat of proper resistance and carrying capacity.

If a fairly large motor generator set is installed it would not be economical to operate it when only one or two batteries are to be charged. To charge these batteries, one, two, or more, 30, 40 or 50-ampere mercury arc rectifiers should be used. The number of rectifiers will, of course, depend on conditions, such as number of cars charged during the day time and other conditions mentioned later. This makes a very economical addition to the garage equipment. Many large garages are using rectifiers in this way.

There are many public garages caring for from 20 to 70 cars using mercury arc rectifiers exclusively with very economical results, and where the variation in number of cells of the various batteries to be chraged is large, a complete rectifier installation may show greater economy than any other scheme.

In very large garages having motor generator sets of from 100 to 500-kilowatt capacity, a smaller capacity set of, say, 15 per cent. of the capacity of the large set should be installed to take care of lighter loads, as for instance during the day time, to make it unnecessary to run the large set except when at least 50 per cent. of full load can be taken from it. This raises the efficiency of the charging plant considerably without introducing any serious complications.

It is very often possible to lower the D. C. voltage of a generator of a large motor generator set to just take care of the battery having the largest number of cells and gradually raise this voltage as the battery charges. This will materially reduce the losses in battery charging rheostats. Every saving of this kind materially reduces the cost of charging.

Current is often wasted by having, on a large generator, to maintain a high voltage to charge one or two high voltage batteries with a large number of low voltage batteries on the same line. For example: If an 100-kilowatt generator were charging two 48-cell lead batteries, and 29 30-cell batteries, all averaging 25 amperes each, it would be necessary to hold the voltage of the generator high enough to charge the 48-cell batteries, or at an average of about 115 volts. If the 30-cell batteries were charged alone the voltage could be held at 69 volts average. The saving would be about 140 kilowatt-hours (about 28 per cent. saving) during a five-hour charge, even figuring on the slight loss in efficiency of the motor generator due to operating at lower voltage. The 48-cell batteries could be charged from rectifiers.

One Hundred and Ten to 125 Volts D. C.—For large or small public garages having 110 to 125 volts direct current, the charging apparatus consists simply of a suitable number of charging or distributing panels already described and illus-

trated, and a charging rheostat for each battery circuit. With the exception of not using motor generator sets, the apparatus will be the same as in the garage having alternating current, the equipment of which has just been described.

Manufacturers make distributing panels with two, four and six circuits each, but if there is any possibility of future increase in requirements the six-circuit panel would be the cheapest to buy even when starting a garage on a small scale. As requirements increase six-circuit panels may be added to take care of the demand and assembled with those already installed to make a complete switchboard.

In many instances where the D. C. voltage is low it may be necessary to put a small generator driven by a suitable motor in series with either the main circuit or with a part of the main circuit feeding the high voltage circuits which may be charging 48-cell lead batteries.

Two Hundred and Twenty to 250 Volts D. C.—The public garage having 220 to 250 volts direct current only is very rare. Such a garage should use about the same equipment as the garage using alternating current supply, except that the motor generator sets should have 220 to 250-volt D. C. motors instead of A. C. motors. The motor generator control panel will have a D. C. motor starting rheostat instead of the starting compensator and a line switch suitable for the voltage. What has been said about distributing panels and charging rheostats applies also in this case.

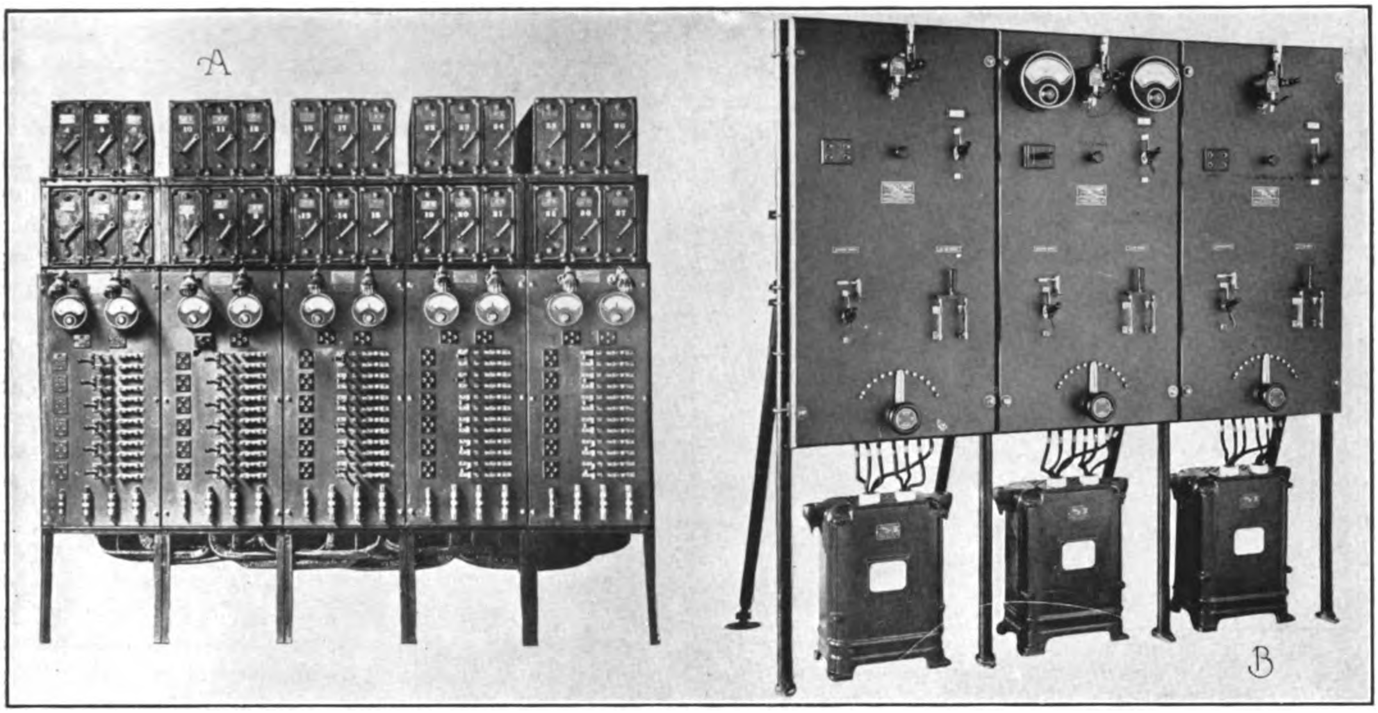
In case it were necessary to charge a high voltage battery of, say, 48 cells lead, it would be connected to the 220-volt supply with sufficient rheostats in series, making it unnecessary to boost the voltage of the generator for one or two batteries,

In these three comparisons it is assumed that other conditions are the same; that is, one is as reliable as the other. If one current cannot be relied upon for continuous service when it would be needed, the other should be taken almost regardless of the cost, particularly in a public garage where failure to charge a battery may result in losing customers or, at least, dissatisfaction.

There are some advocates of the so-called "multi-voltage system" of charging. The idea in this scheme is to reduce the losses in charging rheostats by having generators of different voltages for the different voltage batteries. The scheme is considered impractical by many on account of high first cost, skilled attendants necessary, and the doubtful saving accomplished, all things considered. If such a system were adopted it would be almost impossible to estimate the capacity of each generator of a different voltage. For example, a garage might have 10 24-cell batteries at the time of ordering a generator to charge them and in six months' time they might all be gone. The tendency now seems toward the standardization of the 30-cell battery for pleasure and 40-44 cells for commercial cars. A double-voltage system consisting of an 80-volt generator for 30 lead cells (40 cells Edison) and a 110-volt for 40 lead cells (60 Edison) in many cases will be a simple and economical arrangement. Mercury arc rectifiers in a garage of course constitute a multi-voltage system of units, but as each rectifier will operate efficiently at any charging voltage it cannot have the objections cited above.

The Department Store Garage.

The cars of any up-to-date electric delivery system are usually uniform in the number of cells of battery they contain



Modern Garage Charging Equipment: A, Public Garage Switchboard Fitted with Battery Charging Rheostats; B, Commercial Vehicle Type Rectifier.

causing a great waste on all the other circuits.

Five Hundred to 600 Volts D. C.—The public garage having 500 to 600 volts only available would use a similar equipment to that having 220-250 volts D. C., except that the motor, line switch on the control panel, voltmeter, starting rheostat and wiring would be arranged for the higher voltage.

If the 500 or 600-volt circuit is from a trolley line and varies as such circuits often do from 300 to 600 volts, it would be well to choose another circuit if available. If it must be used the generator of the motor generator set should be specially designed to give approximately full voltage at about one-half speed and a generator voltage regulator installed to hold a fairly constant voltage on the generator.

General.

Some garages may have both A. C. and D. C., in which case the rates a kilowatt-hour may decide which supply is the better to adopt. The following is suggested:

With both A. C. and 110 to 125 volts D. C., the latter is unquestionably the one to use if the costs a kilowatt-hour are anywhere near the same. If A. C. were five cents and D. C. eight cents a kilowatt-hour the large garage would probably use enough current to pay the interest and depreciation on the greater investment and save money by using the A. C. and converting it to D. C. with a motor generator set.

With both A. C. and 220 volts D. C. there would not be much choice and the current carrying the lower rate a kilowatt-hour should be used.

With both A. C. and 500 volts D. C., there is not much choice in the public garage, but in the private garage the A. C. would be safer. Otherwise the current that can be bought at the lowest rate should be used.

and in the number of cells of batteries which are generally of 40-44 cells (or the equivalent in Edison), so that they can be efficiently charged from the 110 to 125-volt D. C. service usually found in the business sections of large cities. Further, all cars as a rule come into the garage at about the same time.

All these facts make it possible to design a very efficient charging equipment; there is little loss in rheostats; the charge can be started on all cars at once, so that if a motor generator set is used it can be operated at nearly full load. Besides it is not difficult to estimate future requirements.

The remarks already made with reference to charging apparatus for various A. C. and D. C. supply circuits apply to this style of garage the same as to others. Arrangements must be made to take care of a small charging load in the day time for forming batteries, etc.; if high current boosting is required at noon, heavy circuits to handle the current must be installed and the generator equipment must be carefully estimated.

If due consideration is given to all conditions it is possible to make this operate more efficiently than any public garage.

Charging Edison Storage Batteries in Public Garages.

The garaging of cars containing Edison batteries introduces some additional complications in the design of charging apparatus which have to be considered if a garage expects to care for them under all conditions.

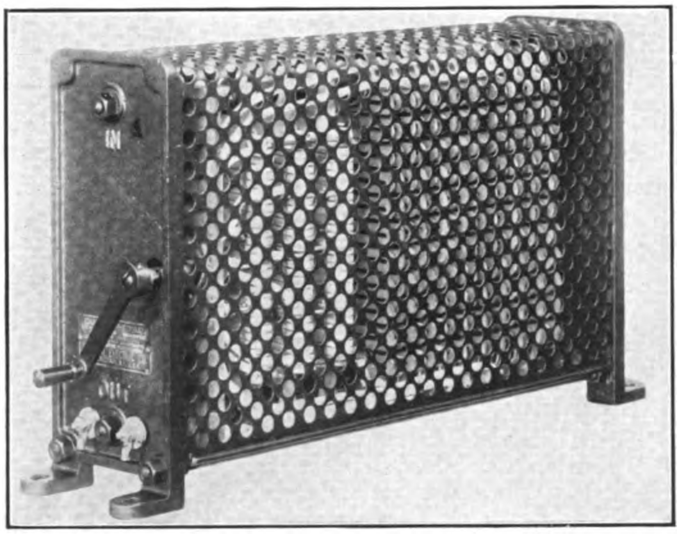
The makers of this battery allow charging rates greatly in excess of the normal rate. For example: An Edison A-8 battery (normal charge for seven hours at 60 amperes) may be charged for 30 minutes at three times normal, 180 amperes, or for 15 minutes at 300 amperes. The maximum voltage under these conditions will be higher than normal, necessitating a higher charging voltage from the generator or D. C. supply.

At three times normal charge rate the maximum D. C. voltage required would be about 1.98 volts a cell, or for a 60-cell battery about 119 volts (normal 111 volts). This battery could not be boosted at much over the normal rate from a 115-volt D. C. circuit. To accomplish this overcharging it will be necessary to boost the voltage of the D. C. circuit to about 125 volts or preferably to 135 in order to take care of any voltage drop in the charging circuit. The voltage may be boosted by connecting a low voltage generator in series with the D. C. circuit. This generator should be capable of delivering about 20 to 25 volts, depending on the boost required, and should be driven by a suitable size 115-volt D. C. motor. Full information on the proper equipment to use can be ascertained from manufacturers of electric motors and generators who are always glad to give the benefit of their experience to prospective purchasers.

The garage of the department store, express or delivery service company using Edison batteries in their vehicles must first see to it that their cars are equipped with heavy circuit and charging cable, plugs, etc., if the "noon hour boost" is to be adopted, or there may be danger from fire due to heating caused by high current.

Special high current or heavy duty charging plugs which will safely carry 200 amperes can be purchased. If the cars are equipped with ordinary 50 to 60-ampere plugs, they should be replaced by these heavy duty plugs before overcharging is practised to any extent.

The generator capacity of such a garage, if motor generator sets are used, must be carefully considered. If all cars are to be boosted at triple rate for 30 minutes, and normal load on the generator represents normal charging rate of all the batteries at one time, it means a 200 per cent. overload on the generator, which is more than it is designed to stand, and a generator of equal capacity should be connected in parallel with it. This generator will also serve as a spare in case of trouble with the other. Of course if only a part of the batteries



Standard Type Battery Charging Rheostat.

are to be boosted the original generator will probably be of sufficient size to handle these batteries.

If such boosting is to be done a sufficient number of extra heavy duty distributing panels, with higher capacity wiring, switches, fuses, heavy duty outlets, etc., should be installed.

Increasing Capacity.

The charging capacity of a public garage can be materially increased, if the hours for charging are lengthened. If a garage keeps a charging operator on duty all night, which is often necessary anyway, three groups of car batteries may be charged from 6 in the evening to 6 or 8 in the morning. Many cars are not used after 6 in the evening and these will start the first group. The second group will begin to come in about 8 and by 10 many of the first group will be charged, so the second group can be started. A third or after-theatre group may be started about 2 in the morning, and all the charging finished by 6 or 8 at the latest. By carefully analyzing conditions of this kind in a garage and insisting upon a certain routine arrangement being followed, a maximum charging efficiency can be obtained and maintained. In this connection it will pay to have in charge of the charging apparatus a man with some knowledge of the savings possible by judicious management, even at a much higher salary.

A great deal more could be said on this subject of charging apparatus, as this paper has dwelt only on generalities and left the details for each garage manager to figure out for himself. As already stated, manufacturers of charging equipments are glad to make suggestions to intending purchasers if requested. In making requests the more complete the information given the more complete will be the suggestions.

The following questions bear vitally on the subject:

(A) Nature of Supply.

1—Alternating or direct current?..............................
2—Frequency (if alternating).......Cycles? No. phases?.......
3—If both A. C. and D. C. available,
give rate on each (alternating.........cents per kw.-hr.

9—Charging apparatus installed at present time?

INTER-CITY TRUCK SERVICE.

Freight Haulage Between Baltimore and Washington Promoted by Business Men.

The railroad companies entering Baltimore and Washington have decided to discontinue the free store-door delivery that has been the vogue in those cities for a long period, and this has been the means of promoting a motor truck freight service between them. The project has been inquired into by several organizations of business men and has been approved by them. A well established Baltimore company is willing to operate the line as soon as it has the assurance of sufficient business to justify the use of two six-ton trucks.

It is expected that a large number of firms that have no delivery equipment and have shipments made from the one city to the other will support the service, as this will give them every convenience desired and at practically the same expense. The saving in time and the delivery at the stores are expected to be factors that will appeal to a large number, and the cost will not, it is believed, be as much as the railroad freightage and delivery charges combined.

L. R. Smith has been elected president of the A. O. Smith Company, Milwaukee, Wis., succeeding his father, A. O. Smith, who died a few months ago, and he will continue as general manager of the concern. Mr. Smith has been identified with the company for years. The other officers are: Vice president, C. S. Smith; secretary, E. M. Smith; treasurer and assistant secretary, James L. Sinyard; assistant treasurer, Joseph J. Stamm; sales manager, James L. Sinyard; directors, L. R. Smith, C. S. Smith, E. M. Smith, James L. Sinyard and John P. Kelley.

The Firestone Tire & Rubber Company, Akron, O., during the fiscal year ending July 31, earned in gross figures approximately $15,000,000; the net profits were $1,600,000 and the surplus was $1,250,000. The net assets of the company of that date were about $7,000,000. The earnings for the year showed an increase of $3,500,000 as compared with the previous year.

SPEED AND DISTANCE MEASURING DEVICES.

By G. F. Matteson.

AFTER exhaustive laboratory tests and practical tests on the road of various forms of speed measuring devices, it was clearly demonstrated that those forms which depended on springs, magnets and delicate mechanical parts would not retain their accuracy for any considerable time and the liquid centrifugal principle was found to be the most accurate and reliable and was, therefore, incorporated in the Veeder tachodometer, Fig. 1, which is a combination of an odometer or distance recorder and a tachometer or speed indicator.

The case contains a colored liquid, which is forced up the glass tube by a paddle wheel attached to a vertical shaft whose speed varies with the speed of the car, being positively driven by a flexible shaft connected to the front wheel. The paddle is double, the lower part being approximately twice the diameter of the upper. The flow of liquid is generally controlled by the larger wheel and the speed is indicated by the height of the liquid and measured by the scale on the right of the tube. This scale is usually graduated to 30 miles. This will be found to be sufficiently high for all ordinary traffic, as few automobiles are driven over 30 miles an hour in actual practise. In order to provide for registering higher speeds a scale reading to 60 miles an hour is provided on the left. A small lever at the right of the instrument operates a two-way valve which directs the flow of liquid to the indicator tube from the larger paddle when the 30-mile scale is used or from the smaller paddle when the 60-mile scale is used.

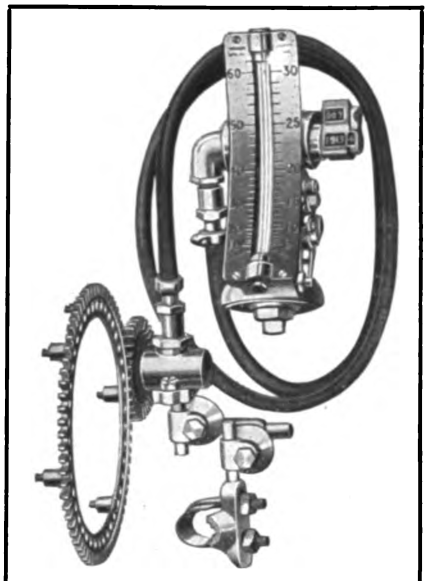

Fig. 1—The Veeder Tachodometer.

The column of liquid is adjusted to the zero graduation when the car is stationary by means of a float within the case, operated by a thumb wheel at the lower right hand side of the case. Ball bearings are provided throughout and all parts are strongly and durably made.

The upper line of figures of the odometer records the miles and the tenths of miles for each trip and may be set back to zero at will.

The lower line of figures records the total miles which the instrument has run and cannot be set back.

While centrifugal speed indicators have an average error of three to five per cent. and magnetic controlled speed indicators have average errors of over 10 per cent., the Veeder tachodometer is guaranteed within one per cent. of error and its accuracy is not affected by vibration, variation in temperature or ordinary wear.

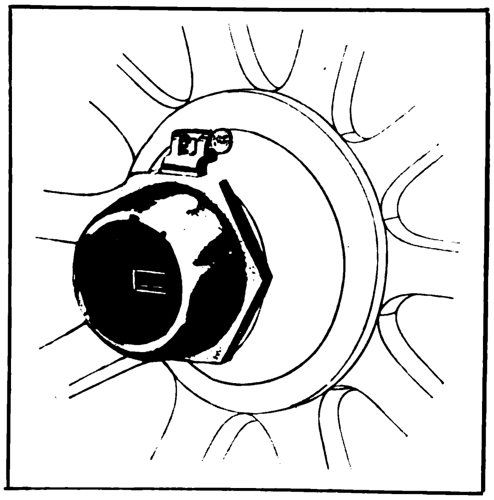

Fig. 2—The Veeder Hub Odometer.

The form D odometer, Fig. 3, is a very popular instrument, which is attached to the dashboard and is operated by a flexible shaft driven by a gear attached to the front wheel. The instrument measures miles and tenths of miles. The three-figure trip register can be set back, but the five-ring register, which records the total mileage, cannot be set back.

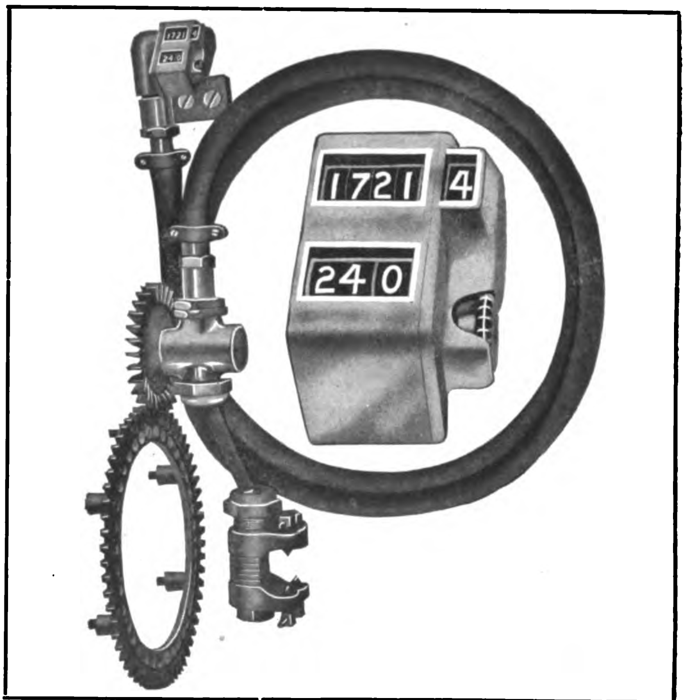

Fig. 3—The Veeder Form D Odometer.

The Veeder hub odometer, Fig. 2, is a most compact mileage register which is attached to the hub of the front wheel in place of the regular hub cap. It is

operated by means of a slot in the end of the front axle engaging with pins attached to a flexible and pressure equalizing mechanism which positively drives the register which indicates miles and tenths of miles.

One type is made so that it will register the total mileage both forward and backward. Another type is made so that it will register only the mileage forward. After attachment to the wheel hub these instruments are sealed so that they cannot be tampered with, thus providing a true record of mileage.

BAKER TRUCK TO TEST TIRES.

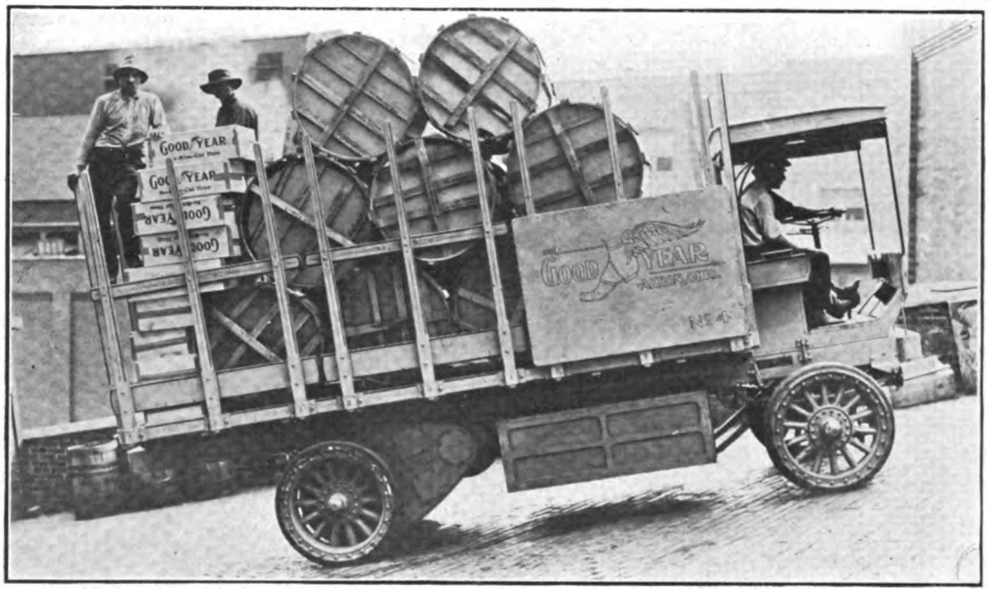
Goodyear Company Utilizes Standard Machine to Develop Special Products.

The Goodyear Tire & Rubber Company, Akron, O., has in its service a 3.5-ton Baker electric truck that was recently delivered and is used for a decidedly novel purpose. As is well known, some of the manufacturers of solid rubber tires have found a demand for shoes that will have high resiliency and yet at the same time endure under practically all classes of work that is practicable with machines. There is a decided difference between the tires that afford the best results with electric and gasoline vehicles. The main object to be obtained by electric truck builders is to minimize the current consumption, with a view of obtaining maximum mileage on the normal battery charge, and careful experiments have developed the fact that the higher the resiliency the less the demand upon the battery.

There is, however, a critical point in resiliency, in that when this has been exceeded the tire will not endure as well, and so the endeavors of the experimental departments of the tire manufacturers referred to are devoted to determination of what compounds will produce both qualities to the highest degree. To obtain definite data it has been necessary to take tires made from different compounds and use them in service that will demonstrate both current consumption and endurance, working them as nearly as can be judged they will be used by owners.

The Baker truck is used as a testing machine to measure the efficiency of all types of Goodyear tires in actual use, and this is done in work between the Goodyear plant and the various railroad terminals, and in exacting tests over the courses selected for observations for resiliency and battery current consumption. The truck is equipped with two sets of wheels, so that tires may be adjusted on one set while the other is in use, and the time of changing minimized.

The possibilities of obtaining satisfactory data with the truck are very large, and according to engineers who have carefully studied tire testing the only certain figures are those that have been made with recording instruments. These can be applied to an electric vehicle and accurate readings obtained, from which charts may be plotted and comparisons made that will show differences very exactly. These records would be extremely costly were they not made in connection with the work of the factory, and by the use of the machine the company is making regular work produce a double result, and in this particular case the electric truck is an unusual economy.



Baker 3.5-Ton Truck, Used by the Goodyear Tire & Rubber Company for Testing Tires, Ascending Steep Grade During Regular Service.

The truck was delivered from the Baker factory in Cleveland, O., to the Goodyear plant in Akron, a distance of 42 miles, under its own power. After arrival the truck was taken about the city by some of the officials of the Goodyear company and driven several miles, during which it ascended Borth hill, one of the longest and steepest grades in Ohio, and at the conclusion of the trial there was sufficient current remaining in the battery to drive several miles. The accompanying illustration shows the truck and a load ascending a very steep grade in its regular work.

The Beaver State Motor Company has been organized at Gresham, Ore., by Gresham and Portland interests. A factory is to be built and the company will begin the production of motor trucks on a small scale.

The International Motor Company has inaugurated a new selling policy in which the customer who pays cash may receive a discount of six per cent. from the regular list price, or may pay a quarter of the value and the remainder in 12 equal monthly installments.

KNOX-MARTIN TRACTOR IN HEAVY HAULAGE.

Replaces Fourteen Horses in Lumber Work at Average Daily Cost of $12.50--In Coal Delivery It Supplants Six Horses at an Expense of $12.

DOING the work of 14 horses, the Knox-Martin tractor, owned by Ellis & Eaton, Stafford Springs, Conn., is hauling undressed lumber out of the woods to the mill of the Levi P. Bridges Company, Hazardville, at an average daily expense of $12.50. This figure not only includes the maintenance of the machine, but the wages of the driver, two men and a boy.

Ellis & Eaton operates a steam sawmill in the woods at Orcuttville, the wood lot being about 2.5 miles from Stafford Springs and some 12 miles from the Bridges plant in Hazardville. The tractor leaves the barn in Stafford Springs each morning, makes two trips from the wood lot to Hazardville, and returns direct from Hazardville to Stafford Springs at night. The daily mileage is therefore a little better than 50.

The road leading from the sawmill, for the first quarter-mile, is composed almost entirely of sawdust and slabs. Then follows about 1.5 miles of dirt, varying from decidedly poor to very good. This leads onto a state road, which is followed all the way into Hazardville. The route lies over a long hill, which is somewhat steep in places, and offers a grade for nearly three miles, although of course, this is not all hill. The tractor takes this on the down grade, when loaded.

Those who are familiar with the construction of the Knox-Martin tractor, made by the Knox Automobile Company, Springfield, Mass., are aware that it presents a three-wheeled construction, the two rear wheels, or the traction members, virtually being the forward wheels of the trailer. The tractor is so designed that, while it may readily be detached from the trailer, when it is attached the combination really becomes a five-wheeled vehicle. As such it takes up no more space than a wagon and a pair of horses, and can be turned in the same radius. This feature is of importance when considering work in the woods.

In view of the fact that Ellis & Eaton contemplated using the tractor in hauling from 5500 to 7500 feet of lumber at a load, the weight of which averages about 1.66 tons to the 1000 feet, according to experienced lumber men, and considering the class of roads over which it was to be operated a portion of the time, the trailer was of special construction. By this is meant that the rear springs and axle were built to carry the loads and withstand the stresses. The extreme rear wheels are of double construction, with two heavy steel tires and two sets of steel spokes radiating from a common steel hub.

It will be seen that the tractor is called upon to haul from 9000 to 12,500 pounds to the load, assuming that the weight estimate given is correct. Two trips are made daily, so that the loaded mileage is approximately 24 miles. The heaviest grade is surmounted in the reverse direction, and this occurs but once each day. The tractor uses about 15 gallons of gasoline a day and about a gallon of lubricant a week.

The items in the expense account going to make up the daily charge of $12.50, include, besides the gasoline and oil, the wage of the driver, $2.25 a day; two men at $1.75 a day and a boy at $1.25. No allowance is made for garaging the vehicle, since it is kept in a building which is available for no other purpose. There has been no expense for repairs as yet, but the total is held to include an allowance for depreciation and interest. The two men are employed in loading the lumber, but do other work in the interim, and it certainly would be fair to include only a portion of their wages. The boy accompanies the driver on the tractor and assists in unloading at the Bridges mill. No provision is made for quick loading or unloading.

The front wheel of the tractor is shod with solid

Knox-Martin Tractor and Heavy Duty Trailer in Service with Ellis & Eaton, Stafford Springs, Conn.

rubber, while block tires are used on the traction members. The truck has not been in service sufficiently long to determine the life of these tires, so it is impossible to do more than estimate the mileage cost on these. If it shall transpire that this estimate has been placed too low, it undoubtedly will be found that this will tend to even up any overcharge that may have been credited to the two men who assist in loading in the woods.

In the beginning it was stated that the tractor was doing the work of 14 horses. By this is meant that it is doing the work that 14 horses could do. No such number of horses has been replaced. When pressed for comparative figures the man in charge of the tractor was unable to give more than an estimate for horses. This was largely due to the fact that Ellis & Eaton has a large farm on which is raised the hay and some of the other products consumed by its horses.

It is contended that there is no way of determining exactly what these products cost the firm, therefore it is impossible to judge exactly what the horse equipment has cost. It may also be pointed out that the expense of caring for the tractor is not as great as would be the case were it to be maintained by a concern in the city. The man in charge is a capable mechanic and spends much of his time in caring for the machine, taking deep interest in it and seeing that it is driven carefully at all times.

There is one feature in connection with the use of a Knox-Martin tractor which is of special interest to the investigator. When the inventor, Charles H. Martin, was about to place the vehicle on the market, through the Knox company, he maintained that it would prove decidedly economical on tires, for the reason that it would be found possible to use steel on all except the front wheel. Ellis & Eaton considered this phase of the situation, but early came to the conclusion that it would not be practical to use steel tires on the traction

The Ellis & Eaton Installation with Light Load of Lumber—Note Difference Between This Improvised Horse Wagon Trailer and That Specially Designed for Heavy Loads.

members. This decision was reached because of the character of the roads in the woods, the surface being composed of sawdust and slabs, as previously explained, and over that portion by which the state road is reached. However, if continued experience bears out the results of the first three months of service there seems little reason for complaint on that score.

But if Ellis & Eaton is unable to give information concerning the use of a Knox-Martin tractor utilizing steel tires on the traction members, it is possible to secure reliable data by considering the installation used by the M. S. Converse Company of Springfield, Mass. This concern is engaged in the retail coal business and has been using a Knox-Martin tractor for the past 15 months. In this instance, steel tires are used on all four wheels under the trailer, the front wheel only being shod with solid rubber. This statement needs a little amplification, however.

Springfield is plentifully supplied with hills, and as true of all progressive cities, many of these hilly streets are paved. The tractor is called upon to haul loads ranging from five to nine tons, although the latter figure is attained only at intervals. The experience of the early part of last winter was such that it was indicated that the best results could not be obtained on these paved hilly streets with steel tires on the traction wheels. Accordingly, block tires were substituted, but only during the winter months, when the streets were coated with snow and ice.

As with the Ellis & Eaton installation, it was found desirable to secure a wagon body of special design. This is entirely of steel, with flaring sides and ends, so that the coal is carried toward the centre by gravity, when the slide at the side is opened. It should be stated that much of the coal delivered to families in Springfield is carried from the wagon to the house in baskets, or bags. This factor is of importance, since it has been found advisable to work the tractor with two and three men beside the driver.

This machine is used on what is termed the long haul work and does the work of three two-horse teams. The Converse company delivers coal in Springfield, West Springfield, Chicopee, Longmeadow and East Longmeadow. Sometimes it is called upon to extend its deliveries to Indian Orchard, but this is very seldom. If it is so fortunate as to secure the contract for supplying the city schools, this contract will include the Indian Orchard district, that suburb being a part of the city proper, although five miles from Court square. Longmeadow, East Longmeadow and Chicopee are each about four miles distant, while West Springfield is a matter of one mile. It will be understood that these distances are computed from the centre of the respective towns and cities.

The tractor averages about 35 miles a day, winter and summer, for deliveries are made throughout the year so far as possible. The photograph reproduced herewith was taken when the machine was about to leave the yards of the company with nine tons of coal. It is explained that the wagon body holds five tons, and the additional four tons are represented by the bags on top.

The daily fuel consumption is about 10 gallons. It will be seen that this is very close to the experience of Ellis & Eaton. The latter concern covers 50 miles a day on 15 gallons, while the Converse company uses 10 gallons in travelling 35 miles a day. In one instance the consumption is 3.3 miles to the gallon and in the other 3.5. The other conditions are practically the same, excepting of course, the matter of tires. The Converse company finds that the tractor has a daily

maintenance expense of about $12, this including the wages of two to three men and the driver.

It readily will be conceded that the daily cost of operating the tractor would be reduced very materially if it were not necessary to employ so many men. It has been explained that the body has been designed to unload from the side by gravity. Were it possible to drive the machine alongside the coal hole and dump the load, as is the custom in many cities, there would be little occasion for the services of but one man, and that the driver. This would eliminate the wages of from two to three men, and cut down that daily expense accordingly.

The Converse company loads its truck from a chute leading from the coal pockets. There is practically no delay in this respect. The unfortunate custom, requiring that coal shall be delivered in baskets, makes necessary the employment of additional men, the number depending upon the distance from the road to the window leading to the coal bin, in order to cut down the waiting time at the other end. Of course, the design of the wagon aids very materially in unloading, since it is the work of but a brief instant to open the slide and fill a basket.

These two installations indicate the economy and efficiency that can be secured through the use of a Knox-Martin tractor. In some respects the Ellis & Eaton work offers conditions that might be regarded as severe from a tractive viewpoint, while the Converse situation presents difficulties in the way of eliminating time. Both concerns are confident that the tractor solves their respective problems in the most satisfactory manner. That this opinion is held by others in the latter case seems evident from the fact that another coal concern in Springfield has placed a duplicate of the Converse equipment in service within the past month or six weeks.

After building gasoline and electric motorettes for a considerable length of time at Hartford, Conn., C. W. Kelsey, who was the head of the Kelsey Manufacturing Company, and later of the C. W. Kelsey Company, has discontinued manufacturing and has retired temporarily from the industry.

The George Grow Automobile Company, dealer in used pleasure cars and service wagons, has removed from Worcester street to the Electric Garage, 331-33 Columbus avenue, Boston, Mass., where it occupies the entire building.

ISSUES NEW BEARING DATA.

J. S. Bretz Company, Importer, Is Mailing New List to the Trade.

The J. S. Bretz Company, 250 West 54th street, New York City, sole importer of the F & S annular ball bearings, is mailing the trade a new booklet which cancels all previous lists relative to the product handled by this concern. The various types are illustrated, including the light, medium and heavy series, also the narrow types, and dimension diagrams are presented. Each bearing is listed, giving the outer diameter, bore and width, ball diameter and number of balls. The load-pounds given are the highest proper for steady loads and speeds.

The dimensions are given in millimeters, but a table of inch equivalents is included, making it a simple matter to convert the measure. Special tables will

Knox-Martin Tractor Loaded with Nine Tons of Coal in Service with M. S. Converse Company, Springfield, Mass.

be supplied on request for other speeds and loads, and for extra sizes where their use is indicated. The single annular type fitted with the narrow ribbon ball separator and the W. H. narrow width ball separator are well known to the trade and the data on these will be of service to the garage, repairman and service station, as sizes and prices have been revised to Sept. 1.

The use of motor trucks by large manufacturers on long distance deliveries has become a custom and the Walker & Pratt Manufacturing Company of Watertown, Mass., is sending four Mack machines over the road to Lynn, Haverhill, Lawrence, Lowell and other New England cities, each loaded with three tons of stoves for local dealers. The Mack trucks have been in constant use by the company for the past 12 months and according to Sales Manager Stevens, without trucks for quick delivery, its business would be greatly handicapped.

ELECTRIC VEHICLE ASSOCIATION OF AMERICA.

The Objects of the Organization, and How the Practical Use of a Well Established Utility Has Been Systematically Advanced Among Business Men.

By Frank W. Smith, Vice President.

THE Electric Vehicle Association of America at the conclusion of its fourth annual convention, to be held in Chicago, Oct. 27-28, will enter upon its fourth year of existence. The first year's work was largely of a formative nature, although much was done during this period to cement and bring together the several factors interested in the promotion and adoption of the electric vehicle, for which purpose the association was formed. Three years of activity finds the association in a very flourishing condition and the incoming administration should look forward with great encouragement for bigger and greater things to be done for the interests for which the association stands.

Frank W. Smith, Vice President Electric Vehicle Association of America.

The membership has steadily increased from year to year until today it numbers within its several grades of membership—active, auxiliary, associate and press—some 430 members. There has been an increase in the membership during the past year of 35 per cent., notwithstanding that some 25 members have dropped from the roll, principally because of discontinuing their activities in the electric vehicle field.

This increase in membership is a most favorable indication and emphasizes the fact that the scope of the association's work is continually broadening. Of especial significance is the fact that foreign influence has been created by the association. New members have been secured from Berlin, London, the Philippine Islands and Canada, with an interesting inquiry as to associate membership from Brazil. So that the association may be said to be of international as well as national influence.

The individual owner of the electric vehicle and the garage owner have not, so far, been included in any great numbers among the membership. No especial appeal has been made to this class. With the growth and larger influence of the association membership within this field can be successfully appealed to.

With the increase in membership and the expansion of the electric vehicle business the experience of important societies, such as the National Electric Light Association, will probably be repeated in the case of the Electric Vehicle Association; that is, the necessity for team work of committees. A quotation from the September bulletin of the National Electric Light Association will serve to emphasize this point:

With the development of committee work of the association have gone the perception and acceptance of the principle that while leadership is ever desirable, what the industry really needs is not simply the expression of individual opinion, but data collected over the whole area and the ripest judgment in its interpretation. Hence, in the affairs of this great body, the committee looms up more and more in authority, and the committee report more and more embodies and enforces the practices that have the largest adoption.

According to figures published at the first of the current year there were some 35,000 electric vehicles registered throughout the several states of the Union. During 1912 8756 vehicles of the passenger and commercial type were manufactured, the output for that year representing nearly one-third of the total electric vehicles under registration; the percentage of increase showing for 1912, 42 per cent. for the passenger and 34 per cent. for the commercial. An output of 15,000 electric vehicles for the year now drawing to a close has been predicted by some authorities, and a census of the 1913 figures will indicate as to whether or not these predictions are to be fulfilled. Certain it is that the electric vehicle industry stands today on the commercial horizon as a potential factor in city and suburban haulage, and that its future is well assured.

That the Electric Vehicle Association has been, at least to some extent, a factor in this development, is conceded in many quarters. That its influence can be broadened and made of greater benefit to the industry as a whole may well be predicted. To this end, important work through the coming year will devolve upon the several committees whose activities are to be looked forward to with great expectations.

Publicity Campaign.

An important branch is that of the publicity committee whose work through the past year will be set forth in its report to be presented before the Chicago convention.

The co-operative educational campaign for the first year came to a conclusion about Aug. 1 last. In this campaign there were a total of 451 separate advertisements inserted throughout the magazines in the several groups of mediums employed. The total cost of the campaign, including all items of expense—advertising, mechanical charges covering drawings, setups, electrotypes, mechanical work, postage and miscellaneous—was slightly over $41,000.

Inquiries were received as a result of this advertising from almost every corner of the globe, and while

the copy was of a general educational character and was not designed to secure replies or definite leads, there were upwards of 2000 inquiries about equally divided as between passenger and commercial vehicles.

In the early spring the advertising committee proceeded to solicit contributions to a fund which would make it possible to carry on the publicity work for another year. The committee reports that to date some $35,000 has been obtained, and it is hoped to increase this fund by at least $10,000 within the next few months. This can only be accomplished, however, by hearty response to the committee's appeal to those interested in the promotion of the electric vehicle who have not so far subscribed to the fund.

The 1913-14 campaign, which will be inaugurated about Nov. 1, will include copy of a somewhat different nature than that heretofore used, being more intensive or specific and not of such a general or educational character as during the first year.

Two booklets will be published by the committee, one "The Story of the Electric Pleasure Vehicle," and the other, "The Story of the Electric Commercial Vehicle." They will be 24 and 32 pages respectively.

The covers will be of the poster effect, original in design and in three colors. The booklets will be printed throughout in two colors, profusely illustrated with different types of cars in various settings, and will contain, as well, actual photographs of the newest models of the manufacturers, with a brief description of the vehicles; only those manufacturers being included who have contributed to the publicity campaign.

The editorial matter takes up the early history of the electric, its reliability, cost of maintenance and an explanation in non-technical terms, with accompanying illustrations of its simplicity and durability.

Artistically printed and well written, these booklets, the committee believes, will be found to influence those who are considering the purchase of an electric vehicle. Each piece of advertising copy will "play up" to these booklets and they will be sent in response to the inquiries which come to the association as a result of the advertising, the inquiries to be followed closely from the secretary's office, with whom the manufacturers will be put in touch.

The committee hopes to interest central station companies, and others, the purchase of these booklets to be included within their advertising literature. The booklets will not be sold with the idea of making a profit on their sale, but at cost, in order to increase the circulation, and thereby add to the general publicity of the association's campaign. Sample copies may be had at 25 cents each upon request to the committee.

Committee on Rates and Charging Stations.

The report of the committee on rates and charging stations, of which John F. Gilchrist, Chicago, is the chairman, has covered the subject for which his committee is responsible in a very exhaustive outline of the situation. Much has been done, as indicated by this report, by the central station companies throughout the country to standardize rates for charging current, and the report indicates a general tendency downward for this character of service.

The report presents a great amount of detail in tabular form and shows, among other items, the rates a kilowatt-hour earned by private and public garages; the number of these garages and charging stations throughout the country, with the cost to the public for the service which they render; the number of electric vehicles reported in each city and the approximate percentage of increase during the past two years, and, finally, a list of central station companies which have reported the number of electric vehicles owned by them, their garaging facilities also being indicated. Curves and other data make the report a most complete and exhaustive one, which will be very helpful to the electric vehicle industry at large.

Insurance Committee.

This committee during the year 1912 was successful in securing a 10 per cent. differential in the rate on liability insurance for electric vehicles over other forms of motor driven cars, and during the past year has secured from one of the best New England companies a further 10 per cent. reduction, or practically 20 per cent. from the standard rates for gasoline driven automobiles and trucks for liability insurance.

Among the other committees are the educational, standardization, operating, records, garage and legislative. The activities of these committees throughout the past year on behalf of the association will be set forth in detail in their respective reports which will be submitted at the coming convention.

Association Sections.

The Chicago and Boston sections of the association have been very active during the year, have held regular meetings, where papers and important topics have been presented and discussed, all for the benefit of the industry. It is expected that a report from the chairman of each section will be submitted at Chicago, where the work throughout the year will be reviewed.

Electric Motor Car Club of Boston.

In addition to the New England Section of the Electric Vehicle Association, there is co-operating therewith the Electric Motor Car Club of Boston, with a membership of approximately 120, comprised of the various local interests identified with the industry.

Prominent in the activities of this club is the employment of a business secretary, devoting his entire time to the exploitation of the electric vehicle along the line of working up newspaper advertising, also assisting the standing committees of both the club and section in the conduct of their work. An up-to-date list of all charging stations, together with a list of electric vehicle owners throughout New England, is also kept by this business secretary.

The excellent work of the Electric Motor Car Club in conjunction with the New England Section has without doubt been of material assistance in the very handsome increase in the sale of electric vehicles in New England during the past year.

A word of commendation should be said of the

splendid work which is being done by the central station and automobile trade journals in publicity for the electric vehicle proposition. Those who follow these publications and read the editorials and articles cannot help but be impressed with the marked attention that is being paid to the electric vehicle as compared with even a year ago. This is a sure indication that the subject is one of very great general interest and that the electric vehicle is today not "coming into its own", but "has arrived."

NEED OF DELIVERY EQUIPMENT.

First Purchase After a Fire Was That of a Motor Vehicle.

The necessity of satisfactory delivery is most keenly realized when such service is developed and it is terminated by the destruction of its equipment. This was the experience of the Cream City Bedding Company, Milwaukee, Wis., recently, when a fire happened that greatly damaged its plant. Quite as necessary as stock was the means of delivery, and within a few minutes after the beginning of business the company bought a KisselKar delivery wagon to replace one lost in the flames, and then the management turned toward securing a stock with which to serve its customers. In this instance the company bought a vehicle like that it had used, being sufficiently satisfied to make no change in its equipment.

A Knox-Martin Tractor and Its Load of 18 Tons of Sand, This Being One of the Largest Road Vehicles in Regular Service.

INTERURBAN FREIGHT HAULAGE.

Improved Road Construction Establishes an Increased Market for Motor Vehicles.

John N. Willys, president of the Garford Company, maker of Garford trucks, is of the opinion that with the very great sentiment in favor of good highway construction, and the willingness of the national, state and municipal governments to build roads that will endure, interurban truck transportation service will be very quickly developed. He believes that there will be great economy as compared with railroad and other carriers, and that with the saving in time as well, the patronage will be constant and proportionate to the service afforded the people. Mr. Willys maintains that wherever a new road is built it establishes a market for motor vehicles, and practically benefits the community to a degree that is little realized.

BIG CONSTRUCTION FUND PLEDGED.

More Than Half of Needed Sum Is Available for Lincoln Highway.

Pledges of more than $5,000,000 have been made thus far to the construction fund now being raised to build the Lincoln memorial highway from New York to San Francisco, according to the treasurer of the Lincoln Highway Association. There is one contribution of $300,000 and the donations range down to very small amounts. The purpose of the association is to raise the $10,000,000 estimated necessary for the work before construction is begun, and to accomplish this the association has created state organizations and sectional and municipal committees to solicit funds and stimulate interest.

A large number of motoring clubs and associations, as well as commercial and industrial bodies, have taken active part in the preliminary work, and it is proposed to interest makers of vehicles, road making machinery and materials, and others who might tangibly benefit from the example of these individuals and concerns. It is expected that a considerable part of the fund will eventually be contributed by farmers and agricultural interests. In the work to be done in Colorado a considerable number of convicts will be employed. During the night of Oct. 31 local celebrations in expectation of promoting the enterprise will be held along the route of the proposed highway.

The climatic conditions in southern California are especially favorable to the use of motor vehicles, and there is probably a greater number of both pleasure cars and service wagons in use there than in any other section of the country. From Los Angeles in every direction are good roads to the suburban towns, and between points and the city the greater part of the haulage is by motor wagons. There is not a section that is not served by at least one, and some by several different transportation lines.

THE ELECTRIC MOTOR CAR CLUB OF BOSTON.

By O. G. Draper.

AS A user and enthusiastic sponsor of the electric passenger and commercial vehicle, Boston now compares favorably with her friendly rivals, New York and Chicago. To be sure, there are not as many trucks in Boston as in New York, nor as many passenger cars as in Chicago, but when one looks back upon the old days and then casts his eyes upon the traffic thoroughfares and the park system of the Massachusetts city, he cannot help becoming confident that the electric has "arrived" in the Hub.

Day Baker, Treasurer of the Electric Vehicle Association of America.

Some years ago, in the infancy of the electric vehicle, Boston financiers, over zealous in their advocacy of the electric, were considerably out of pocket in supporting an electric cab company. Its failure, according to those familiar with the subject, was due to expecting too much from the electric vehicle in what might be called its embryonic state.

The prejudice instilled by this beginning has been dissipated by the marked increase in efficiency of the electric and by two powerful agencies, the aggressive, whole-hearted campaign for the electric vehicle of the Boston Edison Company and the splendid co-operation and collective enthusiasm of the members of the Electric Motor Car Club of Boston.

E. S. Mansfield, Vice President, Electric Motor Car Club of Boston.

The club was organized under the auspices of the company and today the central station men are giving liberally of time, thought and funds to the furtherance of the club's work. The company's support has resulted in developing a large number of electric vehicle and accessory branches and agencies in the city, with a rapid increase in sales and prospective sales.

Organized in April, 1911, the early days of the club saw weekly informal meetings, at which temporary chairmen were selected and pertinent subjects discussed. In the autumn of 1912 a formal constitution was adopted and a president, vice president, secretary and treasurer elected. In the spring of the present year a permanent business secretary was employed and definite plans for increased activities made.

J. C. Codman, Treasurer, Electric Motor Car Club of Boston.

Early in its history the club attracted popular attention by a dinner at which were present representatives of the state and city and many prominent business and professional men. This was followed by two annual parades of electric vehicles which were viewed by thousands, occurring as they did on successive Memorial days. A theatre party, attended by many state and city officials, at which were shown motion pictures of electric fire apparatus in action and views of the parades, also served to awaken public interest. President Day Baker has also given freely of his time in the presentation of stereopticon lectures on the electric vehicle before business organizations.

L. L. Edgar, Secretary, Electric Motor Car Club of Boston.

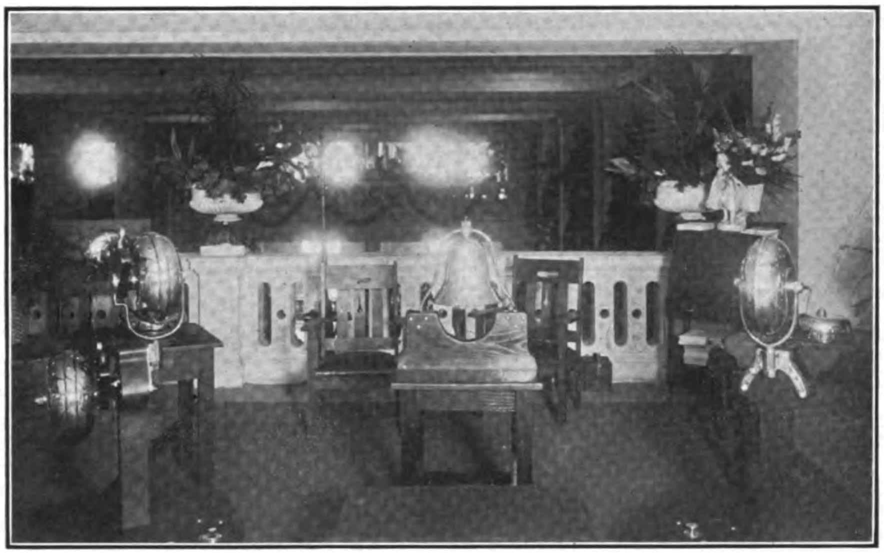
The club co-operated with the New England Section of the Electric Vehicle Association in the sales and advertising convention held last May. Many of its meetings and dinners are held on the same evening as the meetings of the section, the club meeting adjourning in time for all present to attend the section's

lecture. Various committees ably assist officers of the club in carrying on its work, among them being those on meetings, finance, legislation, publicity, membership and charging stations.

Meetings of the organization are held once in two weeks during the busy season, the summer activities consisting of the annual outing and occasional meetings, the executive committee carrying on the work of the organization.

The legislative committee took an active part in the campaign against the motor truck tax bill, which was finally defeated in the House after being twice reported by the committee on roads and bridges and passed by the Senate.

Co-operative and individual advertising has been done under the auspices of the publicity committee, while, co-operating with the charging stations committee, a booklet descriptive of many tours for electric vehicles and containing a complete list of charging stations in the six New England States, was published. At the present time members of the club are co-operating in the publishing of electric vehicle pages in the Boston newspapers.



The Display of Signal Bells Shown at the New York Fire Apparatus Exhibition by the New Departure Manufacturing Company.

The membership of the club when first formed was about 40. This has increased in the two years more than 200 per cent. With the opening of the present season many additional features will be added which will materially increase the club's membership.

The officers of the club during the past year were: President, Day Baker; vice president, E. S. Mansfield; secretary, H. F. Thomson, and treasurer, J. S. Codman. No greater appreciation of their self-sacrificing work in the interests of the organization can be shown than the action of the nominating committee in unanimously reporting them for re-election, with the substitution of L. L. Edgar for Mr. Thomson, who refused renomination because of pressure of other duties.

The club's office is located at 39 Boylston street, where Business Secretary O. G. Draper is present to aid, in all possible ways, both the membership and all others interested in the electric vehicle. Here the resources of the organization are at the disposal of any visitor and any definite information required may be obtained.

CROSS-COUNTRY WITH AN ELECTRIC.

From Boston to Burlington, Vt., at Average Speed of 19 Miles an Hour.

Col. E. W. M. Bailey, general manager for S. R. Bailey & Co., Amesbury, maker of the Bailey vehicles, drove a Bailey runabout, such as is adapted for service purposes, from Boston to Burlington, Vt., and return, the occasion of his visit being the annual meeting of the New England Section of the National Electric Light Convention, Sept. 17-19. The machine was equipped with an Edison battery. The route was through a country through which an electric had never before been driven, and the driver had never been over the road save to Concord, Mass., but had visited Fitchburg, Mass., and Burlington.

The route was through Fitchburg, Ashby, Jaffray, Dublin, Marlborough, Keene and Walpole, N. H., and Bellows Falls and to Springfield, Vt., where the night stop was made, and the following day through Brandon, Middlebury, New Haven and Vergennes to Burlington, a total distance of 258 miles, including numerous detours of from two to six miles because of road repairs.

The average speed for the run was 19 miles an hour, the total running time being 13 hours and 35 minutes. The slowest run was the 42 miles from Keene to Springfield, at 16.7 miles an hour, made almost entirely after dark. The fastest driving was from Boston to Fitchburg, at an average of 21.3 miles an hour. The 78 miles from Rutland to Burlington, including detours, was made at 20 miles an hour. The battery was 60 A-5 cells, and the car had been driven 10,700 miles in 11 months. The machine was given a normal charge at Boston and was "boosted" at Fitchburg, Keene, Springfield, Rutland and Middlebury—the rates varying from 30 to 150 amperes. The normal charging rate is 37.5 amperes. No attempt was made to run an extreme distance on one charge.

The White Company has delivered to Boggs & Buhl of Pittsburg, Penn., two 20-passenger omnibuses, and this firm has established a free transportation service between its store on the North Side and the "down town" portion of the city and the railroad stations. The machines are electrically lighted and started, and are heated. They are upholstered in leather and are in every way attractive.

ELECTRIC VEHICLE ASSOCIATION CONVENTION.

AT THE Hotel La Salle, Chicago, Ill., Monday and Tuesday, Oct. 27 and 28, will take place the fourth annual convention of the Electric Vehicle Association of America, which will be the first meeting of the organization ever held west of New York City. The membership of the association is now approximately 450, representing more than $500,000,000 capital, and it includes, besides the manufacturers of electric pleasure cars and service wagons and their sales forces, the manufacturers of electric vehicle accessories and equipment, battery makers, tire makers and central stations and the owners and managers of public garages.

The purpose of the association is to promote the use of electric vehicles for pleasure and service purposes, and it is broad-gauged in that its endeavors are without reference to any type, class or make of vehicle. The activities of the association are necessarily most productive where the membership is largest, and where organization has permitted systematic and continuous promotive efforts, but in many localities the activity of a single member has brought about a material degree of interest.

The association has three divisional organizations, known as sections, one in New York City, second covering New England and the third in Chicago. These have regular meetings in New York City, Boston and Chicago, but outside of these cities and their suburbs there are not as yet more than casual gatherings. The purpose is to organize these divisions or sections in different parts of the country as rapidly as this can be done effectually, and to systematically educate the people to the qualities, economies and practical possibilities of the electric vehicle.

One of the purposes of the association is to provide for representation for the sections among the officers and directors of the association, and this will be done by the presentation of the following proposed amendment to the constitution of the association. Now the officers include a president, vice president, secretary, treasurer and 12 directors. The amendment as proposed is: "That section 1 of article 5 of the constitution be amended to read: 'The officers of the association shall be a president, three vice presidents and a secretary and treasurer. The offices of secretary and treasurer may be filled by one person. The officers shall be elected from the members in good standing at the annual meeting to be held on the second Tuesday of October in each year. Election shall be by ballot.'"

The delegations from New England and the East will leave New York the afternoon or evening of Oct. 25. The New England delegation will probably start from Boston in a special car in charge of Master of Transportation O. G. Draper, and will be joined at convenient points between Boston and New York by delegates. At New York the New England delegates will join the New York and Philadelphia delegates and a special train will start from that city in charge of Master of Transportation F. Nelson Carle. It is expected that the delegation will be joined en route by others and the entire party from east of Chicago will reach Chicago Sunday evening. At Chicago the headquarters will be at the Hotel La Salle.

The convention will take place at the hotel and there will be morning and afternoon sessions both days. If the expectations are realized there will be upwards of 300 delegates in attendance at the opening, and it is probable that, with invitation extended to the interested public to listen to the proceedings, there will be a large number of visitors. Monday morning the delegates will register at the registration bureau in the lobby of the 19th floor of the Hotel La Salle. The morning session will be called to order at 10 o'clock by President Arthur Williams of New York in the Red Room at the north end of the 19th floor, and following his address will come the report of Secretary Harvey Robinson, the report of Treasurer Day Baker and the reports of the committees on papers, insurance, standardization, garaging, publicity, membership and operating records, will be followed by that of the committee on rates and charging stations. The last will be presented by Chairman John F. Gilchrist. The nominating committee will be appointed at this session.

The first part of the afternoon session, which will begin at 2 o'clock, will be devoted to reports, which will be made for the New York Electric Vehicle Association by Secretary Harvey Robinson, for the New England Section by J. A. Hunnewell of Lowell Mass., the new president; for the Electric Motor Car Club of Boston by President Day Baker, and for the Chicago Section by Chairman Homer E. Niesz. The papers for the afternoon will be as follows: "Traffic Problems and the Automobile", by Dr. E. E. Pratt, manager of the Industrial Bureau of the Merchants' Association of New York City; "The Merchant, the Central Station and the Electric Truck", by F. Nelson Carle, advertising manager of the General Vehicle Company, Long Island City, N. Y., and "Co-Operation Between the Electric Vehicle Manufacturer and the Central Station", by A. L. Callahan, representing the National Electric Light Association. At 6 o'clock there will be a beef steak dinner, served the delegates and guests in the Grand Ball Room at the south end of the 19th floor of the hotel.

Monday evening the delegates will leave the hotel about 8 o'clock in automobiles and will make a sightseeing journey to different electric garages on the South Side, stopping at those best equipped (one of which is referred to as the finest electric passenger car garage in the world), and at several department store garages, and will return to the hotel about 10:30 for a cabaret show and smoker. There will be no charge made the delegates or their friends for the beef steak

dinner, or the cabaret show that will follow it.

The morning session of the second day the nominating committee will make its report and then will come papers on "Charging of Storage Batteries in Unattended Garages", by Maxwell Berry; "Electric Vehicle Salesmanship", by George H. Kelly and E. J. Bartlett; "The Electric Vehicle in Department Store Service", by C. A. Duerr and David B. Tobias, and "Recent Developments in the Lead Battery for Electric Vehicles", by Bruce Ford of the Electric Storage Battery Company, Philadelphia. The election of officers will conclude the morning session.

At 12:30 the Commonwealth Edison Company of Chicago will give a luncheon to all the delegates and their friends in the main dining room of the hotel, and tickets of admission can be obtained from the secretary or at the registration bureau at request.

The final session of the convention will be begun at 2 o'clock in the grand ball room, and it will be devoted to the reading of papers on "Electric Commercial Vehicle Tires" by F. E. Whitney of the Commercial Truck Company of America, the report of the publicity and advertising committee by Vice President Frank W. Smith, and a talk by Ralph Temple of the Ralph Temple Garage Company on "How to Make the Business Healthy."

The offices of the association officers and the various committees and the rooms for exhibition purposes will be on the 18th floor of the Hotel La Salle, and the convention will meet on the 19th floor. The exhibition rooms will be used by those who desire to make displays during the period the convention is in session.

STORAGE BATTERY DEVELOPMENT.

THE Philadelphia thin plate cell, made by the Philadelphia Storage Battery Company, is a development that affords an increase of battery capacity of no less than 45 per cent. This cell has been developed with reference to every other quality as well, and today it is a standard of the industry and is recognized as a product that is in every way dependable and efficient. The Philadelphia cell is a lead type and it is produced with plates varying in thickness proportionate to the duty required of the battery. Four types are made, the thickest of which is designated as W, the next WM, the third WT and the fourth or thinnest WTX, and of these the WT and WTX types are usually provided for vehicle use, where the greatest capacity is required. A cell of any given size will not vary greatly with a variance in plates, although there is a slight reduction in weight as the thinner plates are used, this being due to the use of a greater number of plates as they are decreased in thickness. But the increased surface area exposed to the electrolyte correspondingly increases the amperage capacity, and this is the actual energy that is either charged or discharged.

The Philadelphia cell is built with the purpose of securing a very large measure of endurance, and it is maintained that with normal use the positive and negative plates will have a nearer approach to uniformity of life than is usual with lead cells, this being particularly true of the WTX plates, a result that is largely obtained through proportioning, and the jars in which the element is enclosed are sufficiently deep below the plates so that there is little if any probability, of disintegrated active material accumulating in sufficient volume to become dangerous. In other words, the necessity of flushing or cleaning the sediment from the cell to safeguard against or to prevent short-circuiting, is believed to be remote.

The Philadelphia thin plate is believed to be almost immune against buckling or serious distortion from the effect of charging and discharging, provided that the battery is used as recommended by the manufacturer, this from the fact that the grid or frame is so constructed that the "diamonds" have practically the same effect as the "truss" and the alternating intersections of the diagonal members of the plate effectually lock the active material and prevent its dislodgment during the periods of activity. The "diamond" form of the diagonals and the longitudinals, of which there are five, prevents elongation and warping, and while exhaustive tests have been made with a view of ascertaining the effects of extreme stresses, the construction has endured to such an extent that the strongest claims are made for the cells. The thin plate cells recommended by the company are designed for both pleasure and service vehicle work, where it is essential that high voltages be maintained, and where the demands are at times very heavy.

The Philadelphia cells are made with different sized plates, and with different sized elements, ranging from seven to 21 plates of the W type, from nine to 25 of the WM type, from nine to 29 of the WT type, and from nine to 33 of the WTX type, these being adapted either for pleasure car or service wagon use, and from five to 11 of the C type, seven to 13 of the CM type, seven to 15 of the CT type, and from seven to 15 of the R type, the last four types being intended only for pleasure car batteries.

There are characteristics in the manufacture of the cells and the parts from which they are assembled that are peculiar to Philadelphia cells, and it is claimed that in every respect the material, workmanship and finish are high grade and can be depended upon as being to an extremely high standard of manufacturing. The company also produces batteries for ignition and lighting purposes, which are of equal quality and dependability, and have been as carefully developed for the uses required of them as have been the cells designed for vehicle use. These are made in different sizes and with standardized construction, and are designed for long endurance under extreme conditions. These batteries are supplied either with or without special cases.

THE NEW G. V. MERCEDES SIX-TON TRUCK.

THE General Vehicle Company, Long Island City, N. Y., is now prepared to produce commercially the General Vehicle Mercedes truck, which it will build in one size only. Early in 1912 the company acquired the American rights to manufacture under a license the Mercedes truck or trucks, and it has since that time imported several machines to meet the demands of several customers. With the completion of the new buildings of the plant, work on which has been in progress for about a year, a distinct gasoline truck division will be created, which will have separate buildings and facilities for the production of Mercedes machines.

The purpose of the company is to turn out a high grade truck from every point of view. The Mercedes design was regarded as being thoroughly tested by 13 years' experience in actual service in Europe, and was acquired because of the dependability of the machines in service, and the material and workmanship will be the best that can be obtained. As to factory equipment, there will be no better than that provided for the Mercedes department.

The truck will be practically in duplicate of the machines built in the German factory. It will have maximum speed of 10 miles an hour. The chassis will be standard outside of the motor, for two sizes of engines will be built and either installed to meet the requirement of the purchaser. For conditions where the need of power is extreme a motor rated at 45 horsepower will be provided by the maker, but for work where there is not as great a demand a 35 horsepower motor will be recommended, but either size will be optional with the purchaser.

Though built for heavy work the weight of the machine will be minimized by the use of the best of material and very careful proportioning, and the design is expected to insure unusual endurance and strength. The truck is conventional throughout and the drive will be through a jackshaft carried in combination with the rear axle and by pinions on the jackshaft meshing with internal gears mounted on the rear wheels. Especially noteworthy is the coupling of the driving shaft and the radius rods at a heavy middle cross member of the frame, the driving thrust being practically in a straight line from the rear axle to the frame member, without stress upon the power transmission system. The vertical movement of the rear axle is not restricted and the springs are relieved of all driving thrust. Under normal working conditions there is very little, if any, inclination of the driving shaft.

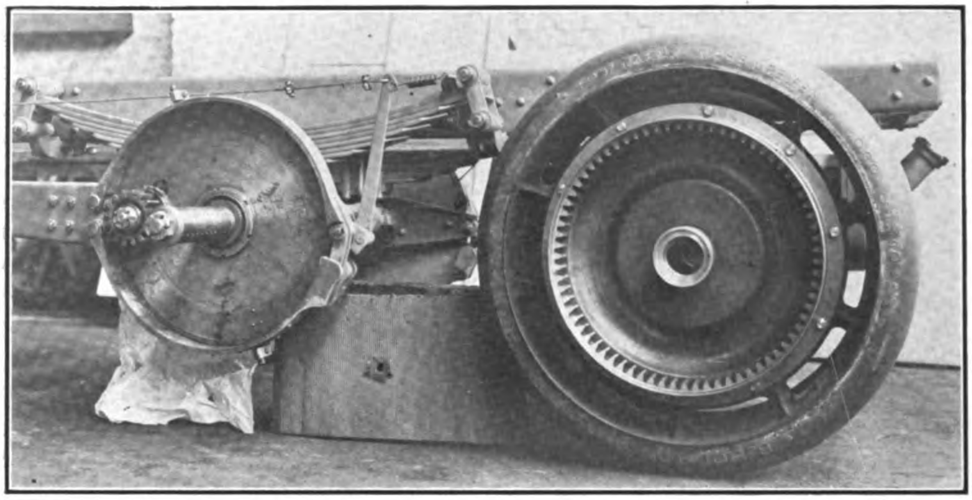
The actual weight of the chassis, with the gasoline and oil tanks and the cooling system filled, is 6380 pounds, and with a maximum allowance of 2000 pounds for a body, which is regarded as ample for any form of equipment, the weight of the complete truck is placed at 8500 pounds. When the truck is light the forward wheels carry 3400 pounds and the rear wheels 5100 pounds, but with a load of 12,000 pounds the forward wheels support 4500 pounds and the rear wheels 16,000 pounds, this placing 91.66 per cent. of the useful load over the rear axle and 8.33 per cent. over the front axle.

The Six-Ton G-V Mercedes Gasoline Truck and a Trailer, Both Loaded, Showing the Capacity of the Machine for Haulage.

The motor rated at 35 brake horsepower at 850 revolutions has a cylinder bore of 4.25 inches and stroke of 5.9 inches, and the motor rated at 45 brake horsepower at 800 revolutions has a cylinder bore of 4.74 inches and stroke of 6.29 inches. The engines are identical save in part dimensions. They are a four-cylinder, four-stroke cycle, water-cooled, I head type with the cylinders cast in pairs. The valves are mounted in the heads of the cylinder units and are actuated by pushrods. Extreme efficiency is claimed for this motor. The speed of the motor is governed by a governor enclosed within the crankcase, and it cannot be tampered with by the driver.

The engine has plain bearings throughout, there being unusual length to the crankshaft journals. The water circulation in the cooling system is actuated by a centrifugal pump. The provision of lubrication is adequate, this being a combination of the force feed

and splash, with centrifugal distribution over the interior of the engine case. The ignition is by a high-tension magneto. The clutch is a cone of large size with wide bearing surface and this is actuated by the customary pedal. The transmission gearset is a selective sliding gear type, affording four forward speed ratios and reverse. These ratios give 1.08 miles, 4.09 miles, 6.98 miles and 10.82 miles an hour. The complete reduction of the driving system is 14:1, of which 4.5:1 is between the pinions at the ends of the jackshaft and the internal gears on the rear wheels.



The Internal Gear and the Driving Pinion and the Axle Spindle of the G-V Mercedes Six-Ton Gasoline Motor Truck.

The chassis frame is a pressed steel channel section of liberal dimensions, and this is 21 feet five inches length. It is mounted on semi-elliptic springs of comparatively slight arc. The front and rear axles are heavy steel forgings. The wheels are of steel, the forward set being shod with 34 by five-inch single band tires, and the rear set is equipped with 40 by six-inch dual band tires. The wheelbase is 169.25 inches and the tread 60.625 inches. The driver's seat is at the right and the speed changing and the emergency brake levers are at the right of the driver. The machine has two sets of brakes, one on the main driving shaft and the other on the rear wheels, the former actuated by a pedal and the latter by hand lever.

The chassis as delivered is fitted with a driver's seat, step, front mudguards, gasoline tank, dash and tail lamps, horn and the usual hand tools.

B. A. GRAMM'S ONE-TON WAGON.

The Gramm-Bernstein Company, Lima, O., has begun the production of a one-ton wagon that in design differs somewhat from the larger machines that this firm has produced, and which in every respect conforms to general practise. The methods of building and the materials used have been determined with extreme care and the vehicles are intended to have unusual life and endurance. The motive power is a four-cylinder, water-cooled Continental motor, having cylinder bore of 3.75 inches and stroke of 5.25 inches, and is mounted on three points. The clutch is a cone and the gearset is a type affording three forward speeds and reverse. The drive is by shaft and jackshaft and side chains. The axles are of unusual size. The two sets of brakes operate on and in the drums on the rear wheels. The springs are long and those at the rear are underslung. The drive is left side and the control levers are at the centre.

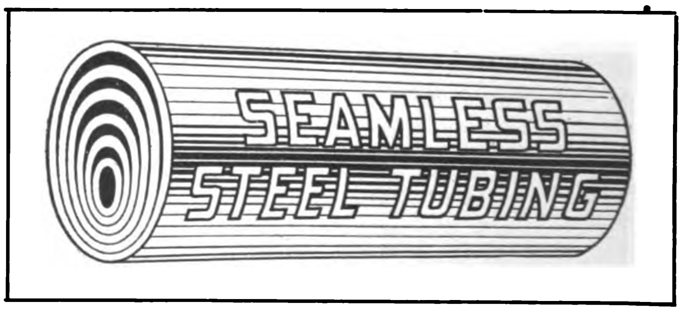
In designing the vehicle care was taken to have all the mechanism very accessible. The motor is carried forward of the dash and under a hood and this is fitted with a standard float feed carburetor and a Bosch magneto. The wheelbase of the wagon is 130 inches and as the frame behind the seat is 102 inches length a 114-inch length body may be installed. The tires are 34 by three-inch forward and 34 by 3.5-inch rear, those of the solid type being used. The gasoline is supplied by gravity from a tank carried beneath the seat.

SEAMLESS STEEL TUBING.

Edgar T. Ward's Sons Manufacturing Wide Variety of Shapes, Also Brass and Copper Tubing.

Edgar T. Ward's Sons, 25 Purchase street, Boston, Mass., maker of round, oval, rectangular and other shapes of mechanical, high carbon seamless steel tubing, is prepared to supply the trade at short notice with cold drawn steel tubing especially adapted for making bushings, jigs, etc., and motor car work. The tubing is constructed to standard gauge, with varying outside diameters and wall thicknesses. The material can be tempered.

The company also produces hot drawn steel tubing with walls of different thicknesses. A specialty is made of brass and copper tubing for gas and oil, it being made in 20, 21 and 22 B. & S. gauge and of different sizes to meet requirements. The company issues a booklet giving complete dimensions, details, etc., which will be mailed free upon application, and is prepared to make any size not listed.



THE NEW ENGLAND SECTION, E. V. A. OF A.

By O. G. Draper.

ENTERING upon its fourth year, the New England Section of the Electric Vehicle Association of America looks forward to a brilliant future for the electric automobile in the six states. This optimism is based upon the rapid growth in popularity in the past three years and upon the type of men who are giving liberally of their time and energy to the furtherance of the organization.

The object of the section may be stated to be the focussing upon its territory of the work of the national organization and the institution of activities of peculiarly local interest and application. In connection with the Electric Motor Car Club of Boston the section is making the electric vehicle an important factor in the transportation world of New England. As an illustration of this there were in New England at the time of the section's inception, approximately 600 passenger and 275 commercial electrics. On Oct. 1, 1913, there were 984 passenger and 574 commercial cars.

The section has contributed to this noteworthy increase in many ways. Through its meetings it has developed the ability of its members to sell cars, it has served to cement all interests in a common cause and has driven home forcibly the superiority of the electric vehicle in its field. Its committees have made possible the making of long tours through the establishment of many charging stations, and have protected the interests of electric vehicle owners from unjust legislation and excessive fees.

A word as to its history. The section was organized April 17, 1911, with the following officers: President, E. S. Mansfield, Edison Electric Illuminating Company of Boston; treasurer, John A. White, National Battery Company; secretary, William F. Kimball, Charles N. Tenney & Co. Mr. Kimball resigned in September, owing to pressure of business, and was succeeded by Wellesley Holmes of the Cambridge Electric Light Company. Its membership in October of that year was about 35.

The following year its activities were broadened. A feature of the year was a trip by electric automobile to the Lynn plant of the General Electric Company, where the members had opportunity to study vehicle apparatus in the making. Among special subjects discussed at meetings were the plans for a belt line electric freight railway in Boston, costs of operation of electric trucks, the 1912 Boston electric show, tires and vehicle meters. Officers were the same as during the previous year, the membership being about 60.

During the past year the section's work was broadened. A permanent business secretary was engaged in co-operation with the Electric Motor Car Club. A two-day sales and advertising convention was conducted with papers on many subjects by leaders in the movement from all sections of the country. Ten states were represented on the floor of the convention. Advertising matter for distribution by central stations among their customers has been prepared.

The officers for the year were: Chairman, Fred M. Kimball of the General Electric Company; vice chairman, Edward S. Mansfield of the Edison Electric Illuminating Company of Boston, and secretary-treasurer, Leavitt L. Edgar of the same company.

During the coming year the following activities will be added to the work of the section:

Under direction of an educational committee courses in electric vehicle practise will be arranged for, both independently and in connection with institutions of learning. Meetings will be held in various cities, the next takng place in Providence, R. I. The legislative committee will watch legislation in all New England states. An attendance and discussions committee will make the meetings more enthusiastic.

Under the leadership of J. A. Hunnewell of the Lowell Electric Light Corporation as chairman, and Messrs. Mansfield and Edgar in their same offices, the fourth year of the section will be its most fruitful, the result of steady growth of an organization of definite aims, aggressive membership and capable direction.

In closing, the attention of electric vehicle owners is directed to the manifest advantages of membership in the section. The educational features, the work of the legislative committee, the information bureau, the development of sanctioned garages and charging stations and the social side of the work will prove a valuable investment for any owner.

Headquarters of the section are established at 39 Boylston street, Boston.

With the installation of new machinery the Spicer Manufacturing Company, Plainfield, N. J., has changed its working schedule from five days and nights weekly to six days a week, with overtime work but a portion of the night. The improved facilities will permit the manufacture of new products later on.

The Weston-Mott Company, Flint, Mich., has added a fireproof building 350 by 75 feet, which will be known as No. 7, to its plant, in which will be located the galvanizing, forging and heat treating departments. In this building the work will be handled progressively and with decided economy.

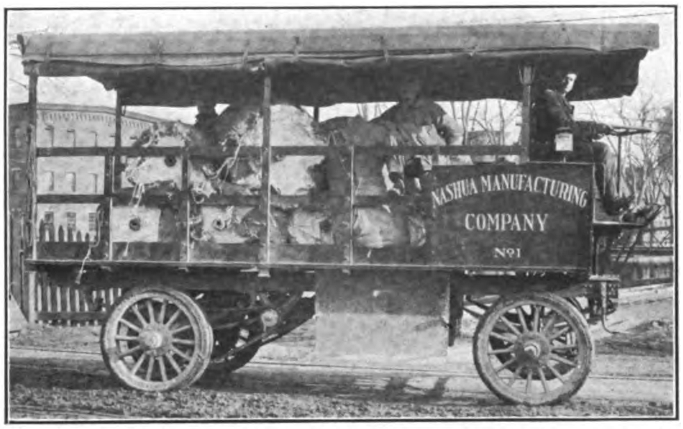
The Lord Baltimore Motor Truck Company is planning to erect a two-story factory building 600 by 125 feet at Canton, O., and will later remove its plant there from Baltimore.

C. C. Bradford, who was manager of the Cleveland, O., branch of the United States Light & Heating Company, has been made sales manager of the company and is now located at 30 Church street, New York City.

MOTOR WAGONS IN TEXTILE MILL SERVICE.

The Advantage of Improved Means for Inter-Factory and Yard Haulage—A Paper by Day Baker, Read to the National Association of Cotton Manufacturers.

"ADVANTAGES of Commercial Motor Cars in Cotton Manufacture", was the title of a paper read by Day Baker, district manager of the General



One of the Two Electric Wagons Utilized by the Nashua Manufacturing Company at Nashua, N. H.

Vehicle Company for New England, at the semi-annual meeting of the National Association of Cotton Manufacturers held at Atlantic City, N. J., Sept. 30-Oct. 2. This association is composed of large manufacturers from all parts of the country, its membership representing the cotton manufacturing industry, which is one of the largest of the nation and in which a vast amount of capital is invested.

Enterprises of this character must of necessity have extremely comprehensive accounting, and it is a general custom to compute to a thousandth of a cent in the house bookkeeping, so that it is practical to assume that costs are probably better realized and are more accurate than with the systems of other industries. This being so, the accounting will permit closer comparison, and these comparisons will determine economies more clearly and precisely than are known by others that have less definite data.

The success of manufacturing is dependent largely upon economies, and whether these be realized in production, in transportation, in handling, or in any work or process, the method that will effect a saving is regarded as justified. The attention given to highway haulage and to inter-department transporting by these concerns is no more than to other manufacturing detail, although until a comparatively short time ago the means of economizing now available had not developed to such practicality that their value was recognized.

Because of the interest in mill yard, inter-factory and general transportation, Mr. Baker, who addressed the first meeting of the year in 1909, was again requested by the association to address the members. The paper was prepared in pamphlet form, which was illustrated by a series of examples of actual use of both highway and factory vehicles, and by a large number of lantern slide views from photographs made in different sections of the country. The paper was devoted to electric wagons, trucks and industrial trucks that may be utilized in mills, shops, railroad and shipping terminals, mill yards and wherever heavy or bulky material or packages are handled. Naturally, the work illustrated was of every character and in widely varying conditions.

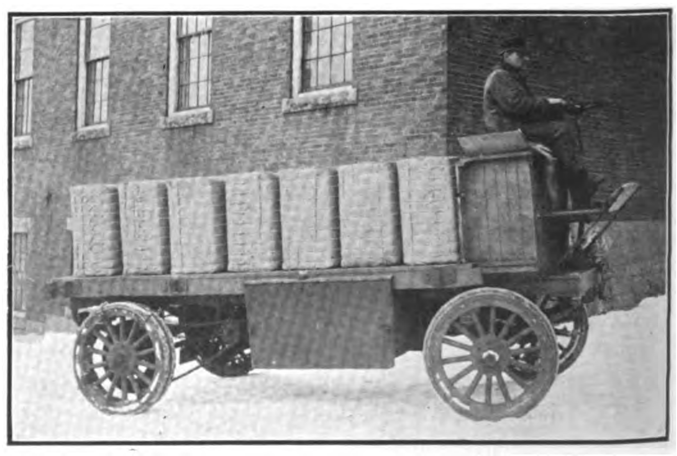
Mr. Baker's paper, so far as it related to highway vehicles, was as follows:

The arguments which I presented before this body four years ago should appeal today stronger than ever to those who in the meantime have not adopted the electric truck, and profited thereby. The four years' experience of those who possessed electric trucks, and the experience of those who have purchased such equipment since, has amply proved the truth of the arguments on economy and efficiency which were then advanced.

The problem, which I am happy to say many mill and factory men have solved, still confronts many agents, superintendents and yard masters; the problem of the proper, expeditious and economical handling of the raw material as it arrives, as it passes through the various processes until it becomes "finished goods", and then is delivered to the storehouse or to the freight house, where the responsibility of distant delivery is turned over to the railroad or steamship line.

Not only are the problems of transportation encountered in handling the actual raw material, material in process, and the finished goods, but in the many contingent parts of mill work there also arise numerous calls for transportation of some character, which work can usually be much better done by motor vehicles than by any other method. As an example, it was recently arranged that an electric winch be applied to one of the yard trucks of a Lowell textile plant. With this electric winch freight cars will be pulled out of a freight shed where locomotives and gasoline driven vehicles are prohibited. This winch will also be used for loading heavy cases. The truck will as well be used for shifting freight cars around the loading platform. These are only a few of the many diversified uses to which an electric truck may be applied.

The bales of cotton or bags of wool and other raw material or general supplies, if not delivered by the railroad direct into the storehouse, must be carted there. Perhaps it is then necessary to team it to the picker room, to start it on its long journey through the course of manufacture. After being spun into yarn it may be necessary to transfer it to a somewhat distant mill. The goods being woven may have to be carted to the bleachery, the dye house or the finishing departments, and from



Two-Ton General Vehicle Wagon Used by the Pepperell Manufacturing Company at Biddeford, Me.

these to other departments or to the storehouse, and perhaps later to the freight house.

Not every mill is so fortunate as to have its coal delivered from the railroad cars or boats direct to its coal sheds or boiler

rooms, and therefore many mills are confronted with the additional problem of the transfer of coal from railroad lines and wharves to their own storage, and from there to their boiler rooms, many mills making two, and some, three transfers.

One-Ton General Vehicle Wagon with Special Body Equipment in the Service of the Pepperell Manufacturing Company.

After the process of combustion, the remnant of the coal (the ashes) must be carted to such places as are being filled, or to the dump. Three of New England's large textile mills are making a profitable business of selling their ashes for sidewalk construction and filling purposes, making deliveries by motor trucks.

The material for shipping boxes does not come in on wings; it requires hauling to the carpenter shop and from there as boxes to the finishing room or shipping department. The barrels of dye and bleaching materials will not roll themselves to the storehouse, and from there to the dye works or bleachery; they must be teamed, and their weight is such that they make heavy loads. Lumber must be moved to the various places around the mill yard where repairs are going on, or if construction work is in progress, bricks, lime, cement, crushed stone and gravel must be carted.

These are some of the many problems that confront the superintendent of the mill or factory.

The Horse Drawn Period.

Years ago almost the only means employed in transportation in the mill yard was the slow plodding oxen, and even now you will occasionally find a few yoke of them slowly drawing their cumbersome trucks loaded with material or finished goods.

Later, as the world progressed and speed became one of the requirements, the more flexible and faster moving animal, the horse, was introduced for service around the mills. The horse, man's faithful friend, has done great work, but his day is fast going. The increase during the past few years in the price of horses, together with the rise in cost of all kinds of feed, is fast putting the horse in the list of luxuries. In addition to the high cost of the horse and his keeping, we are, with the keen competition of the 20th century, calling for an increased amount of work in a given time, less manual labor, a speedier transfer of goods and improved hygienic conditions around our manufacturing communities.

According to one of our best writers on health subjects for the masses, 40 per cent. of the disease and deaths accounted for by our hospitals may be directly traced to the horse, which aided by the wind, the fly and the rat, scatters broadcast death-dealing germs.—"The Horse vs. Health" by Harold Bolce.

It has also been shown by highest authorities that delays in work caused by sickness or death among employees are not only a distinct economic loss to a town, city or state, but also affect the cost of manufacture. Therefore, for the reasons given above, and for the additional good reason that a better and cheaper method has been found, the day of the horse around mills and factories is on the wane.

Twentieth Century Methods.

We no longer weave by hand, nor do we travel by the stage coach, and as the world moves, so the conditions around the factories and mills change. Therefore, we should no longer cling to the use of brute force for the transfer of heavy weights. The lightning subdued by the brain of man, and harnessed by the generator and motor, now stands ready to do our bidding, better, quicker, cheaper and without the unhygienic conditions which surround the stable and the horse.

In order to avoid the fire risk entailed with steam locomotives, various experiments have been made in yard transportation, with compressed air. One of the experiments met with considerable success at the Plymouth Cordage Works, where small locomotives supplied with compressed air drew and shifted industrial cars. But this method was finally abandoned.

In some instances tracks and industrial cars, drawn by small steam locomotives, have been installed in the endeavor to better yard transportation, but the work of almost any mill is of such a varied character that the network of tracks required to reasonably cover the routes desired, the cost of laying them, and keeping in repair, more than offset their apparent saving. And then again, it is often desirable to use the mill yard vehicles around the town or city, outside of the mill property on the public highways. This cannot be done if industrial rail cars are used. Therefore, trackless transportation in and around mills is really what is required.

A Trackless Vehicle Desired.

As vehicles operating around a trackless mill yard and town or city roads must be supplied with power, the nature of the motor is first to be considered. At once gasoline must be discarded except for long runs outside of mill or factory yards, not only on account of the expense of operation and maintenance, but on account of the serious fire risk involved. Electricity seems to be the most natural power to be considered, not only on account of its cheapness, but because of its cleanliness, safety and flexibility. Therefore, the logical method of transportation for the mill and factory yard is trackless, electrically driven vehicles. As the conditions are trackless, the vehicle used must be self-contained, which means that its power, derived from the generator, must be accumulated in storage batteries; therefore, we have given as the desirable method of transportation an electrically driven, storage battery truck.

In considering any method of transportation there are three things to examine: the road, the load and the vehicle. In trackless transportation the road must be accepted as it exists. In mill work the load must be accepted as it is received, and it must be delivered as ordered. These two factors of transportation are the same, no matter what method is employed. Hills, bad roads, frequent stops and starts, long routes or heavy loads are equal in the demand made on animals or machines of any kind. The third factor, the vehicle, is the only one with which the solution of transportation problems can be made any easier.

Just as the electric street car has solved the problem for passenger transportation in cities, so has the electrically driven truck opened the way to a simple freight and delivery system around mill and factory yards, and towns and cities.

The Electric Vehicle.

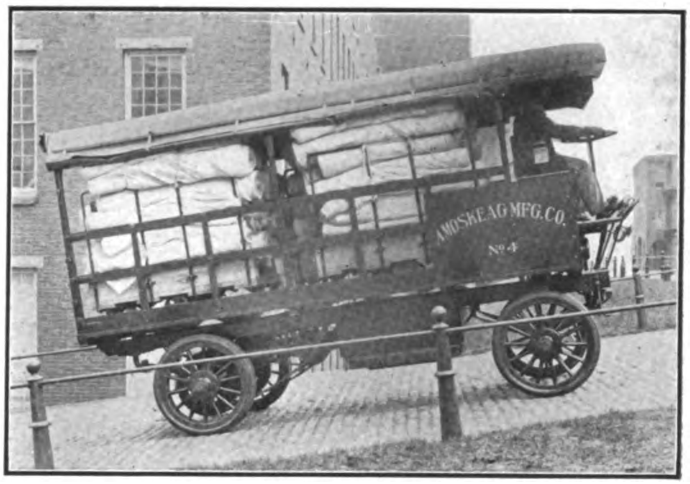
The electric vehicle for trucking and delivery is purely a mechanical proposition. It is a machine. Like other machines it can be built to do a given amount of work in a definite time at a certain cost under any known conditions.

The safely carried load in pounds or tons is the basis of its mechanical design and construction. The specified speed with full load on hard level determines how much power will be required. The specified duration of continuous operation at full load on a hard level determines the amount of energy that must be stored in its battery at one time. This last condition fixes the size of the storage battery. The power and speed required determine the size of the motor and the gear ratios, while the total weight affects the tire design.

The cost of transportation by electric vehicles can be determined just as logically as the cost of operation of any other machine. It is merely a question of measuring the work and measuring the cost and placing one against the other.

Accurate engineering can be applied to the problems of transportation with greater satisfaction with electric vehicles than any other type. Electrical measuring instruments reveal, and record, if necessary, the condition and performance of storage batteries and electric motors. The cost of producing electricity is a known quantity. The amount of electricity necessary to charge a battery is measurable. The amount of electricity delivered to an electric motor by the battery is a known quantity, or can be measured. The performance of an electric motor is accurately specified for any conditions. Its efficiency is easily determined.

The work of moving a ton a mile per hour on a hard level road is expended in starting it from rest and in overcoming the resistance of the road, the tires, the bearings and electrical



One of the Fleet of Electric Wagons Owned by the Amoskeag Manufacturing Company at its Manchester, N. H., Plant.

circuits and the air. If the road is not hard or not level, of course more work will be required to overcome its resistance, or to move the load up a grade. If it is necessary to start often from rest more work must be done than for continuous motion.

To get the cost of operation of its electric vehicles down to the lowest figure the General Vehicle Company has adopted methods that affect the design of the entire vehicle and result in an energy consumption per ton-mile far below any previous figures.

Simplicity has been one of the great factors in obtaining economy and reliability. By referring to the illustration entitled "Power Plant of General Vehicle Electric Truck" you will see that the entire motive machinery of the electric truck is simplicity itself. Four of the simplest forms of mechanism:

A, a series wound motor, practically the same as in use on the thousands of street cars.

B, a Morse silent chain, which in practise is covered from dust and mud by an aluminum case.

C, an enclosed countershaft.

D, standard roller chains.

No gears to change; no clutch; no small parts to wear out or break on the road. No reciprocating parts. The power movement is all rotary. Any mechanic can readily see that with these few moving parts the road efficiency must be high, which, with the low cost of electricity and the low grade of help required to operate, makes a very economical vehicle from the owner's standpoint.

Selection of Electric Vehicles.

The electric vehicle cannot be used profitably where it is not needed. Where the work to be done is less than half the ability of the machine, proper value may not be derived from the investment. Where a large number of vehicles are used the advantages of electricity become more apparent and the efficiency of the service is still more improved.

Transportation by electric vehicles is a subject simple to explain and easy to demonstrate to the satisfaction of anyone interested. The selection of the proper equipment, however, depends on the engineering sense of one familiar with the problem.

Electric Vehicle Economy.

As most manufacturing companies are familiar with the horse drawn proposition, it is of interest to compare that

One of the Three Studebaker Trucks That Have Been Used by the Arlington Mills, Lawrence, Mass., for Several Years.

method with the electric, therefore it may be stated that taking into consideration depreciation, interest, insurance, stable room, shoeing, veterinary charges, harnesses, blankets, stable help and feed, on the horse side of the argument, and the corresponding items against the electric truck, including electric power at four cents per kilowatt-hour, the actual economy in cost shows in favor of the electric truck by 22 to 35 per cent., according to the size and number of vehicles operated and the surrounding conditions.

It should be recollected that the electric vehicle requires only the space it occupies. It needs no hay loft, stalls, harness room, bedding platform or manure pit; nor does it require extra equipment to do twice the work that horses drawing the same capacity per load accomplish. While the stable man is obliged to keep a supply of extra horses to substitute for those which are sick, disabled, or being shod, it is not necessary to have extra motor vehicles on hand, as 98 per cent. of all causes for delay can be provided for in advance and thus prevent or overcome lay-up for repairs.

In a small one-story storage garage, not over 25 by 60 feet, may be housed the complete equipment of five vehicles, which will displace and do the work of nine or 10 horse drawn trucks and 18 to 40 horses, according to the size of truck and the method of working horses. One intelligent mechanic and a helper can easily care for these machines and keep them in first class operating order, while the drivers of the horses in a few days become proficient operators of electric trucks. Notice the economy in stable room and stable help.

While the heat of summer, the chilling rains of the fall, and the low temperature of winter, to say nothing of the glare, icy pavements and deep snow, all work havoc with the health of the horse and make the death rate high; the electric truck knows no seasons, but keeps constantly at its work the year round, good and bad weather alike.

Accustomed as most horses are to moving freight trains and cars, it is, nevertheless, a fact that quite often a good horse will become frightened and run away, causing loss not only to vehicle, harness and load, but frequently irreparably injuring or killing itself or running mate. These incidents all go to make the horse expensive, and form links in the chain of strong arguments for the electric truck.

Arguments Favoring Electric Trucks.

Among the many arguments which should be considered in connection with electric motor vehicle work over horse drawn trucks are: First, the cleanliness in garage and around the yards. The vehicles and the motors driving them, running on very generously proportioned ball and roller bearings, which are sealed, oil and dust tight, require oiling only once in six months, and, therefore, have not the dirt and hot oil throwing proclivities incidental to other forms of motor vehicles. Second, the electric method is much cheaper, requiring a less number of vehicles, therefore less drivers, and the loading and unloading crews are less, or the present force is kept busier. Third, while the current for the charging of the batteries is figured in all commercial estimates on which this argument is based at four cents per kilowatt-hour, it is a fact that most mills or factories can operate a small wheel or a small engine during the night, furnishing power to charge the batteries, or taking current from the lighting plant before the peak of the load, utilizing power which would otherwise go to waste, thus reducing the cost of current to a small fraction of a cent per kilowatt-hour. Fourth, the flexibility in the handling, light or heavy loads carried with equal ease, the turning of vehicle and backing to freight cars, doors or elevators, and its ability, on account of occupying only 60 per cent. of the space used by the horse drawn vehicle, flexible steering, and starting and stopping devices, to travel in congested yards or buildings. Fifth, it can be run into factory buildings, on elevators, into shipping rooms or freight houses, and on docks and wharves, all of which places are barred to the gasoline truck by insurance regulations. Sixth, and most important, the money invested in electric motor vehicle transportation will produce a larger dividend, when compared with present horse costs, than is earned in any other portion of the manufacture of goods.

Just as the electric light has supplanted the candle, kerosene oil and gas, and the electric car displaced the stage coach and horse car, so will the electric truck, one of the most useful inventions of the 20th century, most surely succeed the slow going ox and the expensive horse.

Genius has entered the motor against the quadruped, and all who have witnessed the triumphs of the inventive mind over the clumsier resources of animal strength will realize that the horse must make way for the motor; for science and engineering skill are greater than brute force, and they have produced the electric truck, which is here today as a practical, economical machine.

The Duryea Motor Car Company, Saginaw, Mich., has purchased the delivery wagon department of the Brooks Manufacturing Company in that city and will operate it as a department.

The Chase Motor Truck Company, Syracuse, N. Y., has named N. J. Sherril manager of the districts of North and South Carolina in that concern's selling organization.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC.

Of **The Motor Truck**, Published **Monthly**, at **Pawtucket, Rhode Island**, required by the act of August 24, 1912.

NOTE—This statement is to be made in duplicate, both copies to be delivered by the publisher to the postmaster, who will send one copy to the Third Assistant Postmaster General (Division of Classification), Washington, D. C., and retain the other in the files of the postoffice.

Sworn to and filed with Postmaster July 11, 1913.

ARTHUR H. CAPWELL.

Notary Public.

My commission expires June 30, 1914.

VAN AUKEN ELECTRIC DELIVERY WAGON.

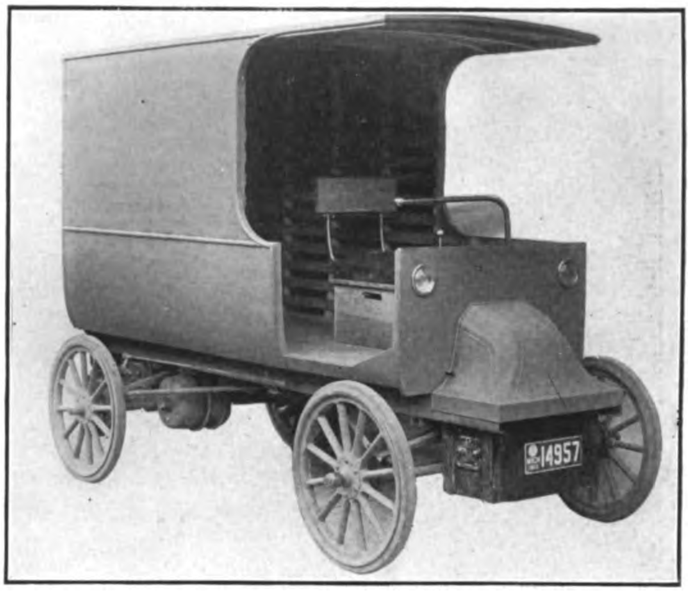
THE Van Auken delivery wagon, built by the Van Auken Electric Car Company, Connersville, Ind., a machine having carrying capacity of 750 pounds, and weighing 1625 pounds without load, has been placed in the market by that concern and will be produced commercially. The vehicle is extremely simple, even for an electric, and it is intended especially for city use, where light delivery made at moderate speed is particularly essential.

In a number of respects Mr. Van Auken has departed from conventional practise and has adopted construction that has been proven satisfactory in other machines. He has reduced weight materially because he uses a comparatively small battery, and he wishes to maintain his mileage as high as possible, and the claim is made that with a battery of but 16 cells from 40 to 50 miles may be driven on a single charge. By exchange of battery, which can be accomplished in less than five minutes, this mileage can be doubled, so that for work that is with a trip within the capacity of the battery unusual economy can be expected.

The wheelbase of the wagon is 80 inches and the tread 51, and the length of the chassis from the dash to the rear end is 90 inches. Back of the driver's seat the loading space is 56 inches. The chassis is not low, the floor being 30 inches above the ground, but the 28-inch wheels cause the machine to appear small. The construction is unusual. The chassis is a steel channel section with strong end and cross members, and this is mounted on two cross springs that are arched above and parallel the axles, the springs being shackled at each end, the swing of the shackles compensating the deflection from the normal form. From the centre of the frame middle cross member radius rods diverge that are connected with the axles at the points where the spring shackles are located, and while these will permit a vertical movement of the axles the relation of the axles is maintained.

Back of this frame middle cross member is another cross member from which the motor is suspended transversely in the chassis, and on the driving end of the armature shaft is a pinion that meshes with a reduction gear mounted on the motor case, and this reduction gear meshes with a gear wheel mounted on the end of the driving shaft. At the other end of the shaft is a second gear that meshes with the crown gear of the differential set. In this shaft at either end are universal joints that compensate for any variance in the height of the motor, and when the body is loaded the shaft is approximately in straight line. A universal joint is at either end of the driving shaft. Practically half the wearing surfaces are included in the driving assembly, there being the two bearings for the armature shaft, two for the motor pinion shaft, three for the reduction gearing, two for the propeller or drive shaft, and four for the differential set, and two in the universal joints, a total of 15. All of these bearings are accessible for lubricating, are protected from water and dust, and should wear for very long periods without attention other than systematic oiling and greasing. The rear axle is a live type with a tubular housing, and the forward axle is tubular. The wheels are 28 inches diameter, and are fitted with two-inch solid tires.

Glancing at the illustration it will be seen that the chassis is remarkably simple. The steering gear is a conventional linkage operated by a tiller, and the brake is a set of shoes expanding in drums on the rear wheel, actuated from a pedal. The battery is divided and is underslung, a crate carrying eight cells being suspended at either end of the chassis frame. It may be removed with ease in very quick time. The arrangement of the terminals is such that no mistake can be made in connecting the battery. The chassis is built



The Van Auken 750-Pound Delivery Wagon with Enclosed Body.

with a short hood ahead of the dash for the machines with covered bodies, but the dash is at the front end of chassis of the open wagons. The resistance is beneath the centre of the body. The controller is a rotary type and is carried beneath the seat of the driver, being operated by a short lever at the left side. The seat is a box that affords storage space and may be lifted conveniently. On the box is placed a well stuffed cushion, retained by straps.

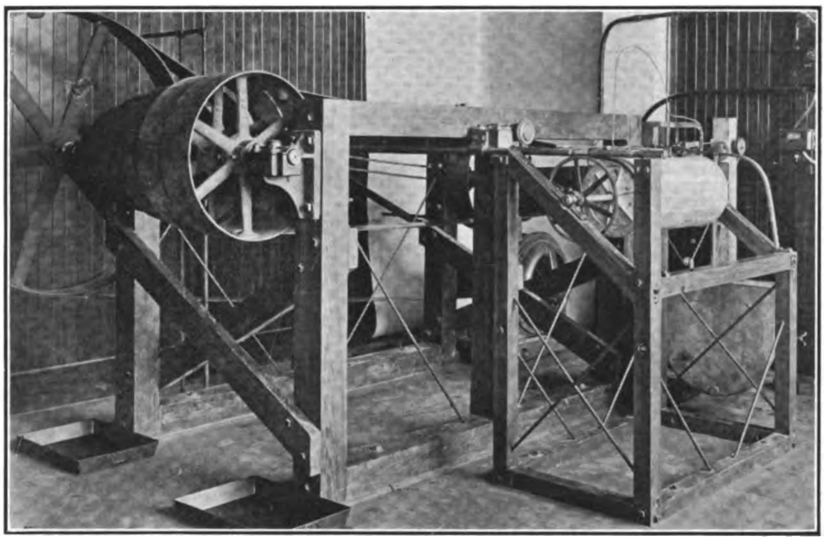
The chassis is fitted with electric dash and tail lamps, a voltmeter, ammeter and odometer. The wiring is large in size and is well protected. Aside from the motor and rear axle assembly there are but 17 places where lubrication is necessary, these being the four spring shackles and spring eyes, the two rear axle bearings, the four front wheel bearings, the two steering spindles, the four connections of the steering gear and the strut rod bearing.

These machines are sold with body equipment complete. The covered type, which is illustrated, has a

regular panel body with entrance at the right side. The left side is completely enclosed. The roof of the top extends forward to the dash, covering the driver's seat. The driver's seat is half the width of the body, so that long packages can be carried conveniently. The length from the dash to the rear is 96 inches, and the space back of the seat is 56 inches length, 41 inches width and the top is 53 inches above the floor. The seat is 21 inches width. The maximum speed is 12 miles an hour and the rated capacity is carrying a load half the distance given as battery mileage.

Charles M. Van Auken, president of the company, was for a considerable length of time engaged in special work for the Ford Motor Company; Guilford C. Babcock is vice president and treasurer; Clarence L. Millard, formerly of the Connorsville Carriage Company is secretary, and O. C. Thompson is chief engineer.

The Wacker & Helderle Undertaking Company has a completely motorized equipment consisting of two hearses, a combination casket and flower wagon and six seven-passenger limousine automobiles, the bodies being mounted on six-cylinder chassis of Premier construction. All of these machines are well equipped and appointed. So far as known this is the only undertaking establishment in the country with only automobile equipment.



Waite Brake Lining Testing Machine Utilized at Factory of Standard Woven Fabric Company, Maker of Multibestos Brake Lining.

The stockholders of the Swinehart Tire & Rubber Company, Akron, O., have increased the capital from $800,000 to $1,000,000 and have elected Fred H. Snyder of Massilon, O., and Charles Curry and T. E. Barry of Akron, directors in the place of Oliver Toomey and T. E. Borton, the last two mentioned declining to continue in the directorate.

The officials of the Mais Motor Truck Company state that there is no truth in the rumor that it was to remove to Columbus, O.

BRAKE TESTING MACHINE.

Standard Woven Fabric Company's Device Eliminates Human Equation.

One of the most interesting machines for testing the efficiency of brakes has been designed and built by E. E. Waite, chief engineer and factory manager of the Standard Woven Fabric Company, Framingham, Mass., maker of the well known Multibestos brake lining. Until recently the most popular method of testing brakes has been to start the car down a steep grade with full power on and the brakes set.

The new machine, which is shown in an accompanying illustration, does away with this primitive method. It has a brake drum of regulation size which revolves within an ordinary brake band. By means of a metal housing, which can be filled with oil or water, any brake conditions existing in any motor car can be reproduced. As this brake drum revolves, there is a certain pull, or tendency for the brake band and brake lining to revolve in the same direction. This is held back by a calibrated pendulum and the amount this pendulum allows the brake band to travel is registered on the chart on a revolving barrel. From this it will be seen that the Waite machine has eliminated the human equation entirely, as the machine itself remains the same for each test, and all that is necessary is to pull the lever on the starting compensator. A thermometer is placed inside the brake drum so that the heat generated by friction can be registered.

Every important factor in braking ability is determined to a nicety. Heat resistance, coefficient of friction, durability, etc. —all are reduced to actual figures. The machine was designed to test different materials and structure of brake linings, and will be utilized to obtain technical reports for the benefit of the sales force of the company. The Waite machine is at all times available to any of the customers or prospective purchasers of Multibestos who care to make tests of brake linings.

A branch has been established at 88 Birnie avenue, Springfield, Mass., by the Mack Motor Truck Company, which distributed the machines of the International Motor Company in New England, which is under the management of E. N. Wright.

H. T. Curtis has been appointed manager of the New England branch of the Invader Oil Company, with headquarters at Boston, and Howard M. Plowman has been made manager of the Philadelphia branch of the concern.

George D. Wilcox has been made manager of the Standard Motor Truck Company, Detroit, Mich.

NEW YORK ELECTRIC AND MOTOR VEHICLE SHOW.

IN MID-AUTUMN, when New York City is thronged with its residents and the flood tide of visiting business people is fullest, one of the events anticipated with much expectancy, and which is an attraction of no mean proportions, is the annual Electrical Exposition and Motor Show. This exhibition is organized by the Electrical Show Company and it is intended to be broadly educational in the use of electric energy for light, heat and power. This show has increased in proportions each year until it has become a national event—national at least in the sense that it is the best demonstration in the nation of the economic possibilities of a utility that is now an actual necessity in practically every community of size in America.

George Fox Parker, Manager, New York Electrical and Motor Vehicle Show.

This exhibit will be made in the Grand Central Palace, Lexington avenue and 46th street, where it was seen last year, and as a show it will be larger and more interesting than ever before. It will be opened Oct. 15 and will be continued until the evening of Oct. 25, during which time visitors will be admitted from 10 in the morning until 10:30 in the evening. It will be exceedingly comprehensive in that it will give innumerable demonstrations of the practical uses of electric energy, as well as its utilization in science and engineering, and these will be of special interest to persons in every phase of life.

Those who associate the use of electric current with lighting and power production will find the exhibition a great education. The utilization of the mysterious force, scientifically developed, will be shown in illuminating, power production, manufacturing, cooking, heating, agriculture, transportation, mining, forestry, telegraphy, telephony, surgery, in army and naval service, in general business and in office use, and in many conveniences and time and labor saving devices that will appeal to men and women. There may be found the elegance desired by the person of large resources or the practicability sought by the most economical: there is what will contribute to health, to comfort, to luxury, to safety and to business facilities and expedition. In every instance it will be shown that the increase of use has brought a corresponding decrease of price, and there will be good reason to believe that eventually electric energy will be utilized as generally in the home as it now is in business.

One of the divisions of the show in which every business man will be concerned is that where electric wagons and trucks will be seen, these being of different types and of sizes suited for every need. The transportation department will include both pleasure cars and service wagons, and these will be displayed by the manufacturers and their agents. The machines will be demonstrated on an oval track 100 yards in circuit on the third floor of the building, and here driving lessons will be given by experts to those who desire instruction before venturing into street traffic.

On this floor will be the model garage, which will be worthy the attention of any person interested in electric vehicle transportation. It will have practical equipment provided by manufacturers of standard battery charging apparatus, including motor generator sets, rectifiers, charging panels and different instruments, and what will make for economy and satisfaction in garaging. Every practical device that will lessen or facilitate labor and afford practical results will be shown in actual use and its value demonstrated. In this garage will be seen all that should be desirable or needed in a public service station, and experts will show the possibilities of whatever is used, from the viewpoint of economy, future expansion and elasticity of accommodation. A complete record will be kept of the operation of the machines, as in actual service.

The garage will be fireproof and aside from the charging apparatus there will be electric vacuum cleaners, air compressors, washing machines, and a battery room where the batteries in use will be given attention by skilled workers. The character of signs generally advocated will be illustrated, and nothing will be left for conjecture or imagination.

Incidentally, the exhibition will have as features a display from the Philadelphia mint, where machines will transform metal into souvenir medals, an electric dairy and poultry farm, a model of a farm irrigated by electric power, a canal display by the State of New York and a model of the Padro Miguel locks of the Panama canal, the latter being sent from the White House at Washington; a model of a United States battleship bridge, and an installation of the new nitrogen lamp, which is a tungsten filament installed in a globe filled with nitrogen gas instead of in a vacuum. These lamps will be placed in the market in a short time. Those to be shown will be of 5000 candlepower each.

The plant of the Victor Motor Truck Company, Buffalo, N. Y., has been purchased by the Clover Leaf Milling Company of that city, and it will be used for milling purposes. The mills of the purchasing concern were recently destroyed by fire.

ELECTRIC WAGON FOR "WHEELBARROW WORK."

COES Wrench Company, Worcester, Mass., a manufacturing concern that has existed for more than a half century, is directed by Frank L. Coes, who has had long experience with different kinds of motor vehicles. He has driven machines for years and has a practical knowledge of automobiles and motorcycles, and for a considerable length of time has used motor wagons for haulage between the two plants of the company and the shipping terminals of Worcester.

One of the vehicles in service is a General Vehicle 1000-pound wagon that is about 11 years old. This machine was originally bought by a concern at Troy, N. Y., and after use for several years it was traded to the maker in part payment for another wagon, and for a considerable length of time was used in New York City as a garage repair and assistance vehicle. Mr. Coes bought it, and after minor repairs, and the change from a tiller to a wheel steer, it was taken to Worcester. It was used about a year for city delivery and was then equipped with an Edison battery and the top cut off and was used for "wheelbarrow work" between the two plants, which are about a quarter-mile apart. The machine is engaged in shifting material from the one to the other constantly.

A One-Ton General Vehicle Wagon 11 Years Old in the Service of Coes Wrench Company, Worcester, Mass.—Frank Coes on the Driver's Seat.

Recently Mr. Coes exhibited the "old-timer" to a number of visitors, and the accompanying illustration was made at that time. Speaking of the wagon Mr. Coes said that it is driven by several persons and no record is made of its mileage or current consumption, but the wagon must be "on the job" all the time. The change of battery was made because of the poor roads and the conditions of use. It carries all kinds of loads, in all weather, and is out of doors all of the working part of the day, being in the garage only at night or when charging. It is frequently run several days with only a noon "boost", for charging is a matter of convenience with the plant electrician.

Mr. Coes says that the wagon is not handsome, but the results obtained demonstrate what can be done with a very old and out-of-date machine with an Edison battery, for so long as the work is done no particular attention is given to it. Aside from filling with electrolyte and painting the outsides of the cells no work has been done on the battery.

As to wagon repairs, what has been done is replacement of a stripped pinion or two when green operators used the reverse for a brake.

The company has in its service a three-ton 1911 White truck and a Ford delivery wagon. The truck has been run daily through two winters and is now in good condition. The machine has been driven more than 30,000 miles and the tires have been renewed all around once, and a new rear set will be needed in about three months. One set of driving chains and sprockets and one set of spark plugs have been worn useless, and the machine has been painted once and varnished twice, this work being done by the company's men, taking advantage of a Sunday and holiday together. The body has been reironed inside because of wear. The total cost of renewals has thus far been less than $200. The Ford machine has been driven more than 5000 miles and has only needed the replacement of two shoes, an old gauge and a windshield glass.

When the gasoline machines were placed in service Mr. Coes inaugurated the "Peter Robinson" system, so-called from the fact that it was originated by Peter Robinson of London, England, and this is the payment of a regular wage for the driver, plus a bonus for each week's service with no repairs and plus a monthly bonus for four consecutive weeks of no repairs. "No Repairs" is defined to mean that no repairs are needed that the driver cannot make, using the shop facilities. Such repairs as the drivers make are made out of hours on all occasions. When the drivers are hired they understand that overloading and fast driving are absolutely forbidden and an infraction of this rule means instant dismissal. When repairs are needed the drivers do the work and receive their bonus. The plant employs an electrical expert and his men do all electrical repairing, and all the mechanical work is done in the

shops of the company. The garages are as well kept as the machine rooms of the plant.

Mr. Coes' comment on his service is characteristic and pointed. He says: "We believe in gas for long hauls and juice for short ones. We have a four-mile trip for outgoing freight, and the same over bad surfaces for incoming freight, and the gas truck is good for five trips a day with an extra lumper or four with its regular crew.

"We believe that the bonus system, with strict living up to the overload and speed rule, will take any commercial vehicle a long way toward satisfactory service in any climate. But we do not believe that the bonus system alone will do anything extraordinary toward truck satisfaction. The trouble with most truckmen is that given a load in view of 1.5 rated capacity, they will make it one trip rather than go twice, even if so doing jeopardizes the truck in every point. Without the bonus system cleaning, foresight of possible troubles, and inspection after washing become merely perfunctory or dwindle into nothingness. With a bonus in view the driver and his lumper become interested; they inspect, test, wash carefully and endeavor to make the truck deliver the service it was built for. The bonus account we consider the best money we spend in our transportation department."

THE A. V. SHOCK ABSORBER.

A Hydro-Pneumatic Spring Device for Eliminating Breakage of Springs.

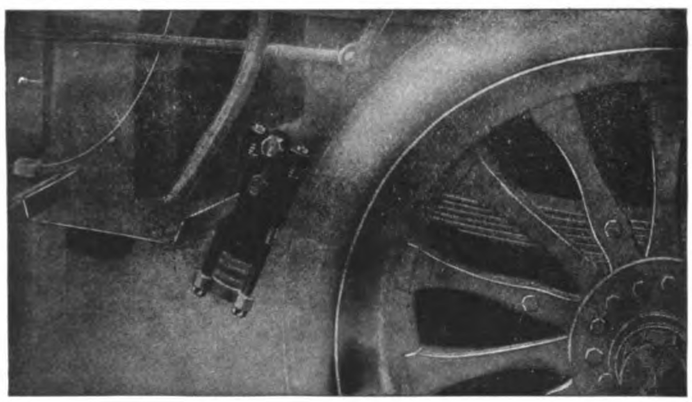
The A. V. hydro-pneumatic spring shock absorber, for which the Hudson Export & Import Company, 140 West 42nd street, New York City, is the sole American selling agent, is a device originated in France and used extensively abroad on both pleasure cars and service vehicles for the prevention of spring breakage and to minimize the effects of road shocks upon the mechanism of motor driven machines. It can be applied to both forward and rear springs.

The shock absorber is a combination of hydro-pneumatic cylinders and supplementary concentric spiral springs which are contained in a chamber. For rear springs there are two communicating chambers and two spiral springs concentric, arranged to replace a spring shackle in tension. The upper spring cover, on top of which is a lug for receiving the hanger, has two concentric cylinder walls, the inner serving as a piston and the outer as a protective sheath. This section also carries a piston that operates within the spiral springs. The lower spring cover carries a third cylinder concentric and telescoping between the other two, and also a cylinder that is concentric with the outer cylinder and into which the piston engages. This lower section also carries four guide stems that are held at the top by a swing bar that is fitted on to the spring bolt. The wall of the central cylinder into which the piston is fitted is perforated with holes of different sizes. The lower half of the absorber is filled with oil.

The movement of the springs will actuate the two parts of the absorber, which is suspended in, or nearly in, a vertical position, either separating or telescoping them. Slight movement compresses the air, which half fills the chamber and the spiral springs, and greater movement will cause the piston in the central chamber to force the oil through the holes in the cylinder wall. As the compression increases the resistance to the piston is more, and as the holes in the cylinder are smallest near the bottom the progress of the piston is resisted until motion ceases. As the pressure is decreased the upward movement of the supplementary springs and the compressed air is resisted by the piston, which must draw through the holes in the cylinder walls the oil that was displaced by the downward movement, and the reflection of the vehicle springs is thus retarded. Obviously the tension of the spiral springs and the rapidity with which the oil can be forced from or drawn into the central cylinder may be graduated to meet any requirement.

The absorbers are made in different sizes for wagons and trucks and may be easily and quickly installed. Being filled in part with lubricant there is negligible wear, and yet as a further protection these may be covered with cases that are dust and water tight.

The absorbers for front springs differ somewhat from the rear equipment in that there is a group of three cylinders, in which spiral springs are placed, and the larger of the three telescopes and the others have springs installed below the pistons. The large and



The A. V. Shock Absorber as Applied to the Forward Ends of the Rear Springs of Motor Trucks.

the small cylinders are connected at the base by passages. The upper section of the large cylinder and a fitting that carries the pistons of the small cylinders are attached to the chassis frame, in the event of a semi-elliptic spring on a pivot. The lower section is attached to the spring eye by the usual bolt. The deflection or reflection of the spring causes the oil to pass from the large to the small cylinders, or vice versa, and the spiral springs take the slight movements and the hydraulic action compensates for the greater motion.

BALL BEARINGS IN ELECTRIC VEHICLES.

By W. L. Batt.

ANY consideration of the design of a self-propelled vehicle must take into first account the operating efficiency of the machine as a whole. When, as in the case of battery propulsion, the source of power is limited, then maximum economy becomes paramount.

The average user of an electric vehicle scarcely appreciates the many points at which a loss of energy in his machine may occur, nor the efforts which have been made by the manufacturer to secure the greatest mileage a battery charge. The liberal use of anti-friction bearings is the most apparent way of realizing the highest vehicle efficiency. Too often, however, bearings of incorrect design and poor mountings are responsible for even a greater loss of power than their omission would have caused.

The modern high grade ball bearing is a most dependable element. It is not only a gradual development of a long period of years, but the result of a series of scientific investigations, by which it was conceived and through which its successful performance was made possible.

As a basic principle the substitution of rolling friction for sliding friction is as old as the history of man. The building of the Egyptian pyramids was probably made possible by such an application and there are in existence today many examples of early foreign construction in which balls or rollers were used.

There was no widespread need, however, for bearings of low power consumption until the advent of the bicycle. Leg fatigue, brought on by wearily pedalling the now ancient velocipede, caused the insistent demand for an easier running machine. Various forms of ball and roller applications served to palliate the evil to a degree.

It was about 1895 when German machine designers, seeking a new efficiency, attempted to make use of the anti-friction bearing for their then comparatively heavy service. Failure followed every attempt. It was assumed as a demonstrated fact that anti-friction bearings were unsuitable for heavy work.

One of Germany's largest industrial organizations, the Deutche Waffen und Munitions Fabriken (German small arms and ammunition factories), believed to the contrary. Arrangements were made with the then famous testing laboratories at Neubabelsburg to take up the entire subject of anti-friction bearings, to investigate without prejudice all forms of ball and roller bearings and their combinations and to report to the waiting engineering world what it might expect. Years of investigation followed. The results clearly demonstrated that more was to be had from what is now known as the annular ball bearing, than from any other type, of either ball or roller bearing.

On the basis of those investigations the DWF first began the manufacture of the modern ball bearing for heavy duty. It is that bearing in a somewhat modified and considerably improved form which made the gasoline motor car possible, and which is being used equally well in the electric vehicle.

When the great number of points at which valuable power may be thrown away in an electric vehicle are considered, it is surprising that more attention has not been given by designers to possible economies that may be effected here and there. There are, roughly, five elements in an electric car at which some power must inevitably be lost. Those are in order:

(1) The motor.

(2) The drive; this may be either by jackshaft and chain or by a longitudinal shaft and bevel or worm gear.

(3) The wheels on their axles.

(4) The friction between tires and supporting surface.

(5) Windage.

The amounts of power lost from these various causes obviously differ in different vehicles and there is a certain irreducible minimum of loss which will not be affected by any care or carelessness of the operator of the car or by its maker. The purpose of this article is to discuss only those losses of power due to the bearings and to show where that loss may be increased or decreased by the builder of the car and where by the user of it.

(1) The Motor—The revolving element of the motor is carried on two bearings, one on the pinion end and the other on the commutator end. This armature revolves at high speed and should always be mounted on high grade ball bearings. The prime advantage of ball bearings over roller bearings is found in their easier and smoother running and in the ease with which the armature can be located endwise by a single bearing. Plain sleeve bearings require an excessive amount of power and entirely too frequent attention, to call for consideration.

These bearings must be sufficiently lubricated and yet there is danger of over-lubrication. A surplus of oil or grease will quickly find its way over into the motor housing, covering the surface of the commutator and soaking the windings. A little attention will show just how much lubricant should be added from time to time to replace that which works out of the housing.

(2) The Drive—There is undoubtedly in the average case a greater loss of power in the drive than in any other one element. Where an exposed chain is used, this is the chief offender, though suggestions without end have been offered with a view to reducing that loss. The bearings on the jackshaft are usually ball bearings and being easily gotten at, may be given the necessary attention, without danger of

an excess of lubricant. Where ball bearings are used, it is very desirable that the mounting should be such as to avoid an overhung load. The bearing should be under the centre line of the sprocket, in order that it may not be affected by the deflection of the jackshaft.

In the case of the bevel or worm drive, there is a very considerable end thrust from the pinion. The best practise calls for the use of a ball thrust bearing in combination with an annular ball bearing for shaft support radially.

(3) **The Wheels**—Current practise is about equally divided between the use of ball and roller bearings for front wheels, though ball bearings for rear wheels seem to be unquestioned.

There is undoubtedly a large amount of end thrust imposed on front wheel bearings, due in part to the angularity of the wheel with reference to the ground, but in large measure to momentum of the car on curves and to the shock of collision with curbings, tracks and such. There is no reasonable doubt but that ball bearings properly selected and mounted may be depended upon for the most severe service.

Unfortunately in the past, small size ball bearings and improper mounting have in many cases caused trouble. This is, however, quite as true of roller bearings. The latter are usually of the adjustable type and if set up too tightly may consume an unbelievable amount of power as well as cut themselves to pieces. The prime advantage of the annular ball bearing is that it is not at the mercy of any man with a monkey wrench.

It is important that care be used that water does not get into the wheel hub and cause rusting of the finely polished bearing surfaces. The hub should be tightly packed with a good grade of clean grease until the grease exudes from around the cap in the rear. Under ordinary conditions a filling every few months with clean grease is sufficient.

With the friction of tires and supporting surface and windage, the ordinary operator is more or less familiar.

That too much care cannot be taken by the manufacturer in his selection and mounting of the anti-friction bearings, and that a little attention to their maintenance from time to time is a paying thing, ought to be evident. The results are directly measurable in increased battery life and decreased cost per mile of operation. That this saving goes on from day to day and year to year should be a spur to the thoughtful designer to use only the best type of bearings, even though their first cost be a trifle higher.

LONG MILEAGE ON SINGLE CHARGE.

Atlantic 1000-Pound Wagon Makes Remarkable Demonstration in Delivery.

A demonstration that is regarded as very unusual, which was made under observation and later sworn to by the driver of the machine, took place in New York City, Sept. 26, when John Savage of Newark, N. J., drove a 1000-pound Atlantic wagon 83.4 miles in delivery work. The Atlantic Vehicle Company has made numerous tests of its machines to determine the mileage with standard equipment under working conditions, and this trial was a continuation of the series, it being made in delivery service for the Riker-Hegeman Company in New York.

The machine is equipped with a battery of 44 13-MV Hycap-Exide cells and a Veeder hub odometer. It was driven from the garage of the Yellow Taxicab Company, East 25th street and Lexington avenue, to four of the Riker-Hegeman stores, where packages were taken on for delivery. Savage was accompanied by a boy helper and two observers. The packages were delivered on either side of the city north of 13th street and south of 97th street. After the last delivery was made one observer and the boy were dropped and the machine was driven from 105 East 15th street to 162nd street and Fort Washington avenue, where the second observer was left, and then the wagon was returned to the garage of the Yellow Taxicab Company in East 25th street.

During the period the machine was on the road it was not charged and when the garage was reached the odometer indicated 133.9 miles. At the start the reading was 50.5 miles, and the indication showed that the wagon had been driven 83.4 miles, on a single charge of the battery. Fifty stops were made.

The MOTOR TRUCK

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. IV. PAWTUCKET, R. I., NOVEMBER, 1913 No. 11

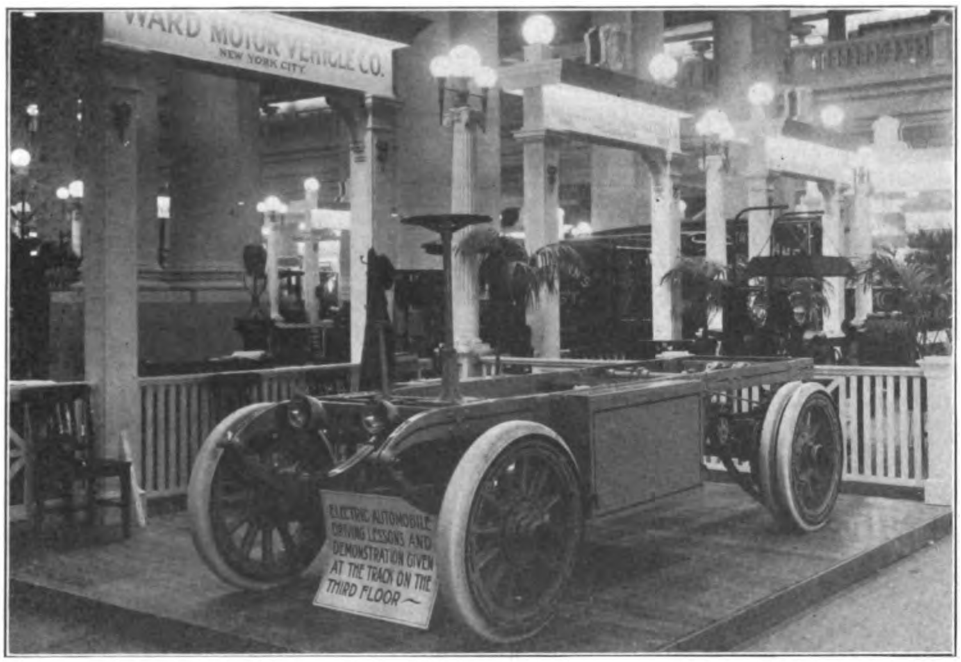
TRUCKS A FEATURE OF ELECTRIC SHOW.

Motor Vehicle Department of the Annual New York Exposition, Only Service Wagon Display of Metropolis, Afforded Gratifying Results---Standard Types of Chassis and No Innovations Characteristics of the Exhibit.

ELECTRIC service wagons and trucks were shown by practically every exhibitor in the vehicle division of the Electrical Exposition and Motor Show, that took place at Grand Central Palace, New York City, Oct. 15-25 inclusive, which was the only opportunity that makers of such vehicles will have, in all probability, for exhibiting in the Metropolis for a year. While there will be a show of pleasure automobiles next January, as has been the custom for the past 14 years, no wagons or trucks will be displayed.

The exposition, from the viewpoint of those who made exhibit, was in every way satisfactory. The degree of interest obtaining in the machines was surprising, and the possibilities with their use were brought to the attention of many thousands who would not have had similar opportunity to learn of them. The Electrical Exposition is an annual exploitation of the advancement of electric science, not only by the residents of New York, but by people in all parts of the country. At these shows every use of electric current for light, power and heat that can be economically made for industrial, commercial and household purposes is demonstrated.

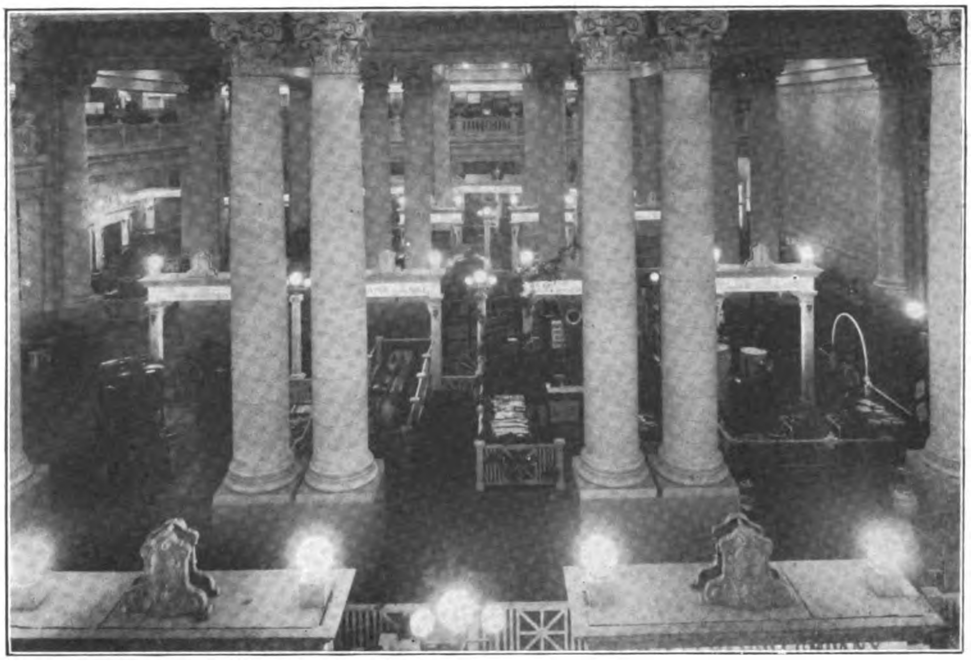
While the number of exhibitors was small, if comparison be made with the great displays of pleasure vehicles, it should be remembered that the great electric manufacturing concerns, those that produce batteries, charging apparatus, motors, controllers and equipment for vehicle and stationary installations, were represented by very large exhibits. Here should be stated that the electric industry is, so far as the building of vehicle motors, controllers and vehicular, garage and service station equipment is concerned, confined to a few very large companies, known thoughout the world as makers of high grade products.



The Stand of the Ward Motor Vehicle Company, a Characteristic Display of the New York Electrical Exposition and Motor Vehicle Show.

The Electrical Exposition attracted many thousands of people daily. While the number actually interested in electric vehicles was but a small part of the whole, the exhibitors, with greater or less experience, without exception stated that the business prospects developed were extremely gratifying.

The show as a whole was spectacular because of the lighting effects, and the attention given to decorations suited for all purposes, and the exhibits included those made by the bureau of forestry of Department of Agriculture, of the bureau of the census of the Department of Commerce and Labor, the Isthmian Canal Commission, the bureau of mines of the Department



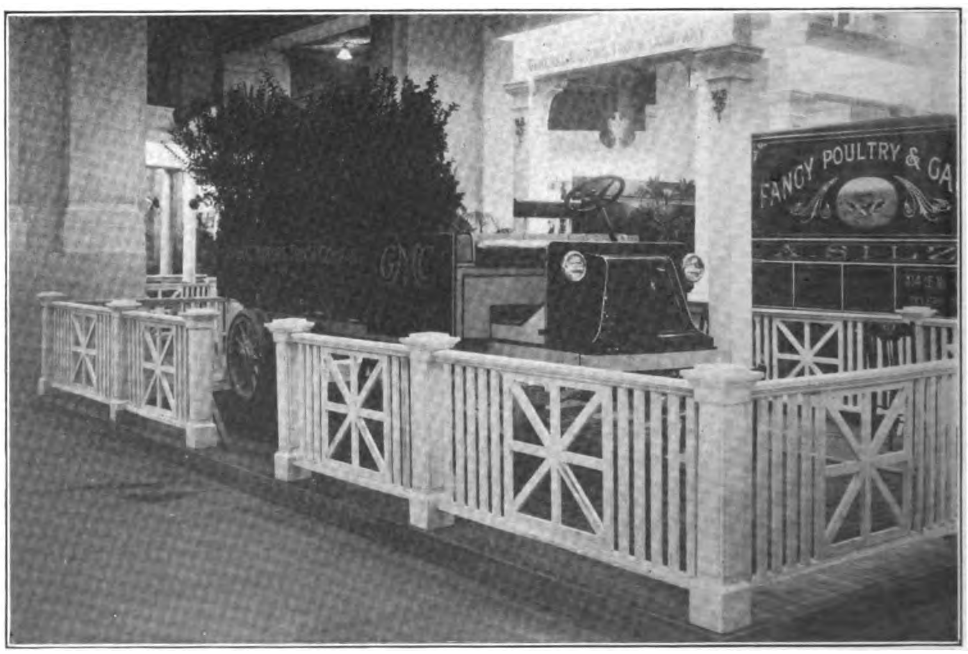
View of the Central Section of the Main Floor of the Grand Central Palace, Showing a Great Diversity of Electric Utilities.

of the Interior, the bureau of standards, the reclamation service, a mint shown by the Treasury Department, as well as elaborate displays by the United States Army and Navy departments; by New York State and by the bureau of municipal research of New York City. Besides a model hospital there were numerous exhibits of apparatus for the administering of electro-therapeutics, and a large number of displays of electric equipment and devices for lighting, heating, household purposes, office work, manufacturing, irrigating, farming and differing means of communication and signalling.

Batteries were displayed by four concerns, three making lead-acid cells and one a nickel-iron cell, and three other companies showed a very wide range of products. Besides these two others showed materials and equipment, and in the model garage was a diversity of productions furnished by a number of makers. The garage was established in the west half of the third floor, with sectional walls built of metal sheathing and wood, to demonstrate fireproof construction. At the entrance and exit of the garage were displayed the signs that have been approved by the Electric Vehicle Association of America.

The garage had a large storage space, a charging panel and rectifiers, and a motor generator set for supplying current. The battery room was fitted with every facility for equalizing, rebuilding, testing, charging and discharging cells, and the machine shop was equipped with a milling machine, shaper, lathe and portable electric drills, and a full set of all necessary hand tools. The General Electric Company supplied a 30-ampere mercury arc rectifier and a six-circuit switchboard. One section of the repair shop was fully equipped for tire maintenance. The garage was designed to show the simplicity of equipment required, the certainty of operation, and the form of installation that, by increasing the units, would meet all future requirements. The educational value of this display was large and the garage was examined by all visitors who were concerned in motor vehicles.

One well informed relative to the vehicles could but be impressed by the fact that there were comparatively few changes in them. In fact there could be no stronger emphasis made of the soundness of the engineering and construction. But one new vehicle, that is, new to shows, was seen, this being the Champion, built by the Champion Electric Vehicle Company, Owego, N. Y., in three sizes, 750, 1000 and 2000 pounds capacities. There is nothing radical in the Champion wagons, the two lighter machines being driven by shaft and the battery being installed beneath the driver's seat. The larger is a conventional type with the battery carried in an underslung cradle, and driven by a double-chain reduction. In careful inspection of



The Exhibit of the General Motors Truck Company, One Standard Chassis Being Sufficient to Demonstrate the Entire Line Built.

Display of the General Vehicle Company, Which Included a Machine for 11 Years in the Service of Arnold, Constable & Co., and the New Worm Driven 1000-Pound Wagon.

these wagons one learns that there is nothing experimental utilized. The designs have been carefully developed and along engineering principles that have been well established by experience and practise. These machines have been built of high class material and of components produced by the manufacturers of standard products, so that there is assurance that the purchaser will always have available in the event of need the resources of the best known concerns in the industry instead of those of a single concern.

The Champion company has built the vehicles that might be demanded by the greatest number of concerns, especially those required for comparatively light and quick delivery, and these in chassis details are in accordance with approved practise. The bodies are built to meet the requirements of the buyers.

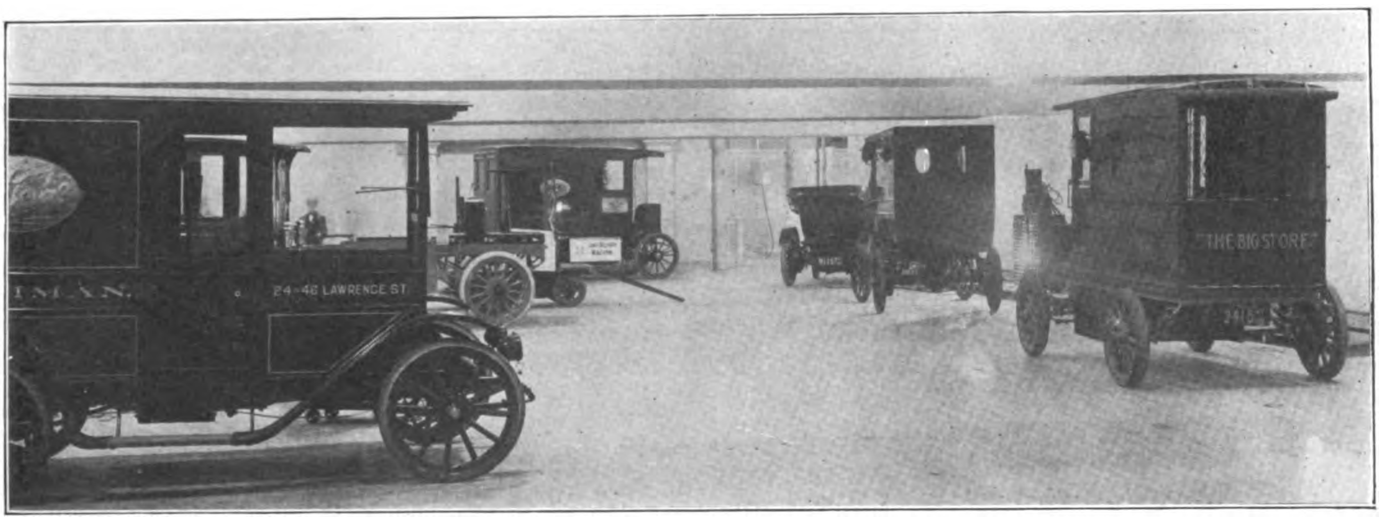
The General Vehicle Company showed for the first time the new shaft driven (worm and gear wheel) machine that is described in another section of the magazine, and this was seen as a stripped chassis and with a panel body. Next to this was seen one of the General Vehicle wagons of 1000 pounds capacity that has been in the service of Arnold, Constable & Co., a widely known New York department store, for more than 10 years, and with a refinished body the old machine was not only sightly, but was exceedingly attractive. This showing afforded comparison of design and construction, and was surely a satisfactory demonstration of the endurance of the electric.

The General Motors Truck Company displayed a single electric truck chassis, this being built to a standard design that is adopted for both wagons and trucks, this having the flexible shaft drive from the motor to the jackshaft and the reduction by side chain. With this design the battery is carried above the chassis, under the seat of the driver, and the instruments, controllers, etc., are protected by a small hood ahead of the dash.

The display of the Ward Motor Vehicle Company was a single chassis, this being the standard design that was adopted a year ago and which has been continued without change. This machine is the careful development of an experience of more than a decade.

The showing of the Couple-Gear construction was a converted horse brewery wagon that had been in use for a number of years and had been adapted by the installation of a fore body containing a battery, mounted on two Couple-Gear wheels. This method of conversion has been the vogue for a long period of time and has been demonstrated to be practical and economical.

The exhibit of S. R. Bailey & Co. was of a chassis that is utilized for passenger cars as well as light service wagons, and a machine was shown that had been

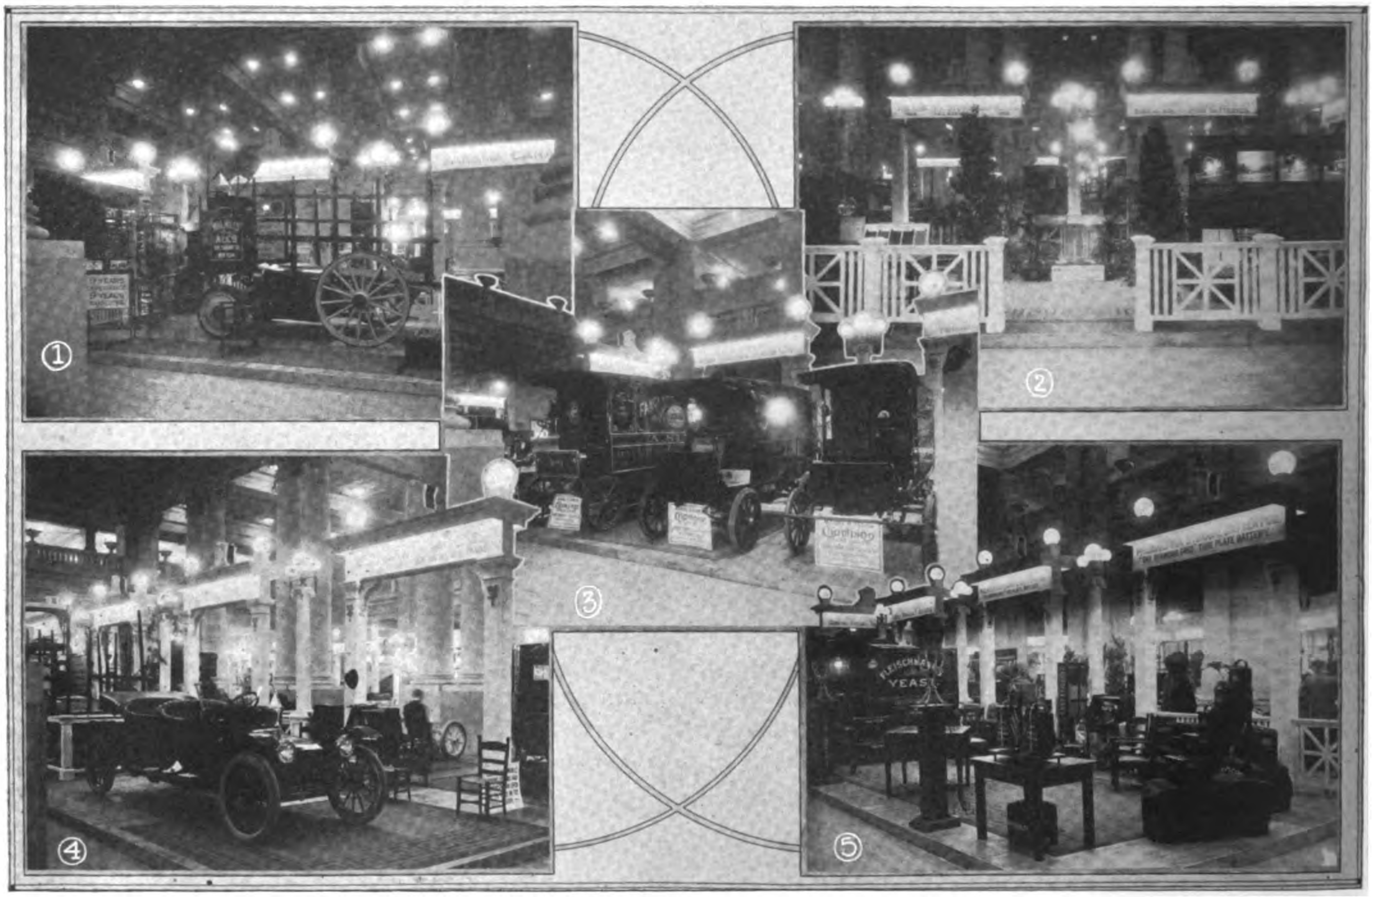


Section of the Model Garage on the Third Floor of the Grand Central Palace, Fitted with Every Facility for Efficient and Economical Care and Maintenance.

driven from Boston to New York by Col. E. W. M. Bailey at an average speed of 21.5 miles an hour, including all time required for meals and recharging the battery. In this same car Col. Bailey left the Grand Central Palace at noon Oct. 19 and drove to Chicago, much of the time through severe rain that made the roads very heavy.

The pleasure cars shown were displayed by S. R. Bailey & Co., and by the agent for the Standard Electric Car Company.

Besides the machines shown in the exhibition spaces there were numerous types and sizes seen in the garage, where they were to be found when not operated on the demonstration track. This track was also used to instruct owners and operators in controlling the machines before permitting them to venture into traffic.



Some of the Exhibits That Featured the Grand Central Palace Show: 1, the Converted Horse Wagon-Truck Shown by Clarence E. Smith & Co., Couple-Gear Agent; 2, the Stand of the Electric Storage Battery Company; 3, the Exhibit of Champion Wagons Made by the Henry Tobin Company; 4, the Display of S. R. Bailey & Co.; 5, the Exhibition by the Philadelphia Storage Battery Company.

The exhibits of the General Electric Company, the Westinghouse Electric & Manufacturing Company and the Wagner Electric Manufacturing Company were of very general character and included many utilities besides those that could be used or required with electric vehicles, while the Electric Storage Battery Company, the Philadelphia Storage Battery Company, the Edison Storage Battery Company and the Gould Storage Battery Company exhibited different types and sizes of cells, both in and out of trays, sectional cells and parts, and by different apparatus demonstrated capacity, endurance and the different qualities claimed for the batteries.

One of the interesting displays was that made by the Rhineland Machine Works, which included ball bearings suitable for electric vehicle construction, and the H. W. Johns-Manville Company at its exhibit showed a number of vehicle and garage accessories and fire extinguishers.

The traffic department of the Automobile Chamber of Commerce has announced a new rate for freight to California that has been fixed by the Transcontinental Freight Bureau to become effective Dec. 1, in which there is a reduction of 50 cents a hundred pounds on motor wagons, which are now billed at the same rate as passenger cars, and mixed carloads, both passenger cars and wagons, will be received if the aggregate weight be sufficient. The minimum weights are 10,000 pounds for a 36-foot car, 10,000 pounds for a 40-foot car, and 12,000 pounds for a 50-foot car.

The Sewell Cushion Wheel Company has established itself in a larger and more commodious factory at Gratiot and Beaufait avenue, Detroit, Mich.

E. S. Thompson, formerly department manager, has been made sales manager of the Motz Tire & Rubber Company, Akron, O.

CLEANING SEWER WITH A MOTOR TRUCK.

Large Economy from Use of a Chassis and Specially Designed Equipment That, with Crew of Three, Replaces Six Carts and 12 Laborers in Service at Pawtucket, R. I.

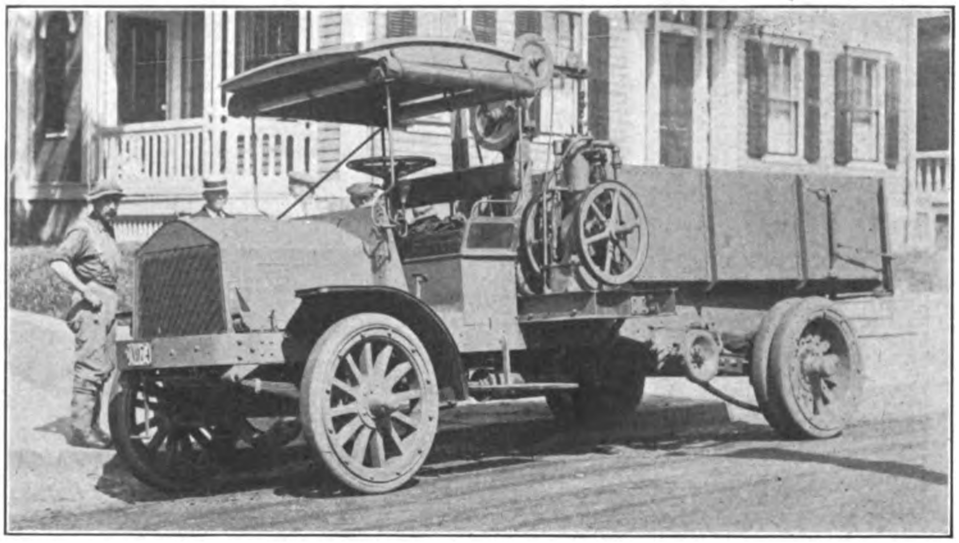
ONE of the problems that each progressive municipality has to deal with is that of satisfactory drainage, and the best system of sewerage is not effective unless it is in condition to carry off the water that may accumulate from rain or melting snow. To dispose of the surface water sewers are constructed, with frequent basins for collecting water, and these are usually bottle shaped and covered, with an opening at the level of the roadway and a manhole for cleaning. The outlets from these basins are generally at about half the depth and are covered with hoods, with traps in the outlet pipes to prevent gas and odor from arising. The basins are several feet deeper than the outlets, to prevent sand, dirt and street refuse washing into and obstructing the sewers, and these basins collect accumulations that must be removed from time to time.

The cost of cleaning the catch basins is considerable, according to the locality and the flowage of water, the manner of working, the distance of cartage, the wages, the method of inspection, etc. In Boston, for instance, the cost of cleaning a basin is approximately $5, and of this as much as 40 per cent. is paid for inspection. The work is usually done by shovels and buckets, and the carting by horses and carts. The basins vary in capacity, but the average will contain about three cubic yards of material, and this is a large load for two horses. With hand cleaning when a basin is well filled the sand must be removed with spoon shovels until a man can enter the manhole. If there is water in the basin the hood of the outlet must be removed and the water bailed into the outlet. Then the solid matter is shovelled into buckets and raised to the street and placed in the cart. Under ordinary circumstances two men, one of them a driver, is necessary with each cart, and inspectors are required for a certain number of carts, this depending upon conditions.

The City of Pawtucket, R. I., now has in the service of its department of public works a Standard truck chassis specially equipped for catch basin cleaning that is probably the only equipment of its kind in America, and it has proven a decided economy in that it has replaced six two-horse carts, and its crew of three men do the work of 12 laborers, saving at least a third of the expense of the work previous to its installation.

The use of the machine was decided on after careful observation of the possibilities, and the detail of the equipment was worked out by the foreman of the city's garage, a mechanic of unusual ability and skill. The truck is fitted with a steel dumping body that is lifted by a hydraulic hoist operated by the engine, and on the chassis back of the cab is carried a two horsepower motor that drives a crane hoist and a water pump by which the manholes are emptied. The body has a capacity of 87 cubic feet and the machine without load weighs 10,600 pounds. The body and mechanism weigh about 3000 pounds and largest load that has been carried weighed about 7800 pounds.

The city has about 1100 sewer basins to clean and there are few available places for dumping the loads. The longest haul is approximately 2.5 miles. The working day is nine hours, and as no work was done when rain fell, much of the time of the horse outfits and crews was given over to haulage, two carts usually working at a single basin so far as this could be done. The increased capacity of the truck and the greater speed in hauling were regarded as the principal factors to recommend it, and the hoisting and pumping apparatus installed was with a view of facilitating the working of the men and minimizing standing time.



The Standard Truck in the Service of the Department of Public Works, Pawtucket, R. I., Specially Equipped for Catch Basin Cleaning, with Dumping Body Lowered.

In the equipment of the truck care was taken to so install it that the chassis was not drilled, all parts being clamped to the frame, and when desired the body and hoists may be removed and the machine can be utilized for any other purpose. The body is of steel plate and angle steel and is 27 inches deep, 108 inches length, 48 inches width at the forward end and 57.5 inches width at the rear end. The ends are covered for two feet with splash plates to prevent the contents, if liquid, from being thrown out. The end gate is a

steel plate and when it is closed it is made practically water tight by the use of heavy rubber gaskets. The body can be elevated so that the floor will incline at an angle of 40 degrees, and the contents discharged by gravity.

Back of the cab and forward of the body is a space 27 inches width on which is installed the mechanism. In the centre is the cylinder for the hydraulic hoist, and this is carried by a frame of two parallel six-inch I beams with cast steel cross members. The frame is 84 inches length, the ends projecting the same distance that do the hub caps. This frame is clamped to the chassis frame. At the left end of the frame is mounted a two horsepower Fairbanks-Morse single-cylinder, two-cycle motor, there being slots in the frame cross members so that it may be adjusted longitudinally. This motor is cooled by the cooling system of the main engine. A pipe connected with the base of the radiator carries the water to a point directly below the small

The Specially Equipped Standard Truck and Its Crew Removing Accumulations from Street Catch Basins, the Bucket Being Lowered After Dumping.

engine and a small pump circulates it through the cylinder; thence the water is carried by a pipe to the rear cylinder of the main engine and forced through the cylinders and the water manifold to the radiator, this providing a means of keeping the main engine warm in the event of cold weather and a stop of considerable length. The exhaust pipe from this motor is connected with the exhaust pipe of the main engine.

On the centre of the frame is mounted the upright hydraulic cylinder. This was built of a section of heavy pipe, a base being cast and welded to the pipe. The piston is forced upward from the bottom of the cylinder and the piston carries a large rod that operates through a stuffing box and a tightly fitting plate. This rod carries a cross arm or head, on the ends of which are large deeply grooved pulleys. Attached to the front of the cylinder and near the top is a pulley at right angles to those carried on the cross arm, and around this is passed two turns of the cable, the ends being carried through the pulley flange and over the pulleys on the cross arm, and down to the ends of the two cast steel arms that are attached to the front of the body, and which drop at either side of the cylinder when the body is lowered. As the piston moves upward the pulleys on the cross arms turn and the body is lifted. The piston can be operated at a pressure of 220 pounds, and when the top is reached the oil used by-passes, but the piston will descend in about 15 minutes time if the engine is stopped. By a release, however, the body can be dropped in about 20 seconds.

The hydraulic pump is beneath the cylinder and it is operated from the transmission gearset of the chassis. An opening was cut in the gearset case and a bronze case was fitted. This case carries the end of the hoist pump shaft, on which is a pinion that meshes with the intermediate speed gear of the gearset. This shaft extends backward and the rear end is carried in a bearing carried on a frame cross member. At the rear end of the shaft is a sprocket that is coupled by a chain with the hoist pump. The hoist is operated by a hand lever at the right of the control levers in the centre of the cab floorboard, and this engages or disengages the shaft pinion with the intermediate speed gear. The driver can, without moving, hoist or lower the body.

On the main shaft of the auxiliary engine, which extends inboard to a bearing near the centre of the frame, and close to the engine, is a keyed-on sprocket that carries a link chain that drives a countershaft below the frame, and this countershaft extends to the right side of the chassis frame. This shaft operates a train of gears on the right side of the frame that carry a shaft on which is a clutch, and this in turn operates a shaft carrying a drum on which a cable is wound. By means of an idler gear the hoist can be reversed. Mounted on the frame is an upright of steel angle with a fitting at the base and top that carries the tubular upright of the crane, and from the head of this tubular member extends an angle steel arm. This arm is strengthened by a diagonal support from the upright to the arm of the crane. On this arm, directly above the upright, is a grooved pulley carried on a standard, and between the angles of the arm at the outer end is mounted another grooved pulley. The cable from the drum drops below the frame, is carried under a grooved pulley below the crane standard and through the standard and over the two pulleys on the arm, the end of the cable being attached to a snap hook. This hook carries the bucket.

At the right side of the chassis, back of the crane, is a small folding platform, and between the sections of the platform, as is shown in the sketch, is a lever that is connected by linkage with the clutch on the

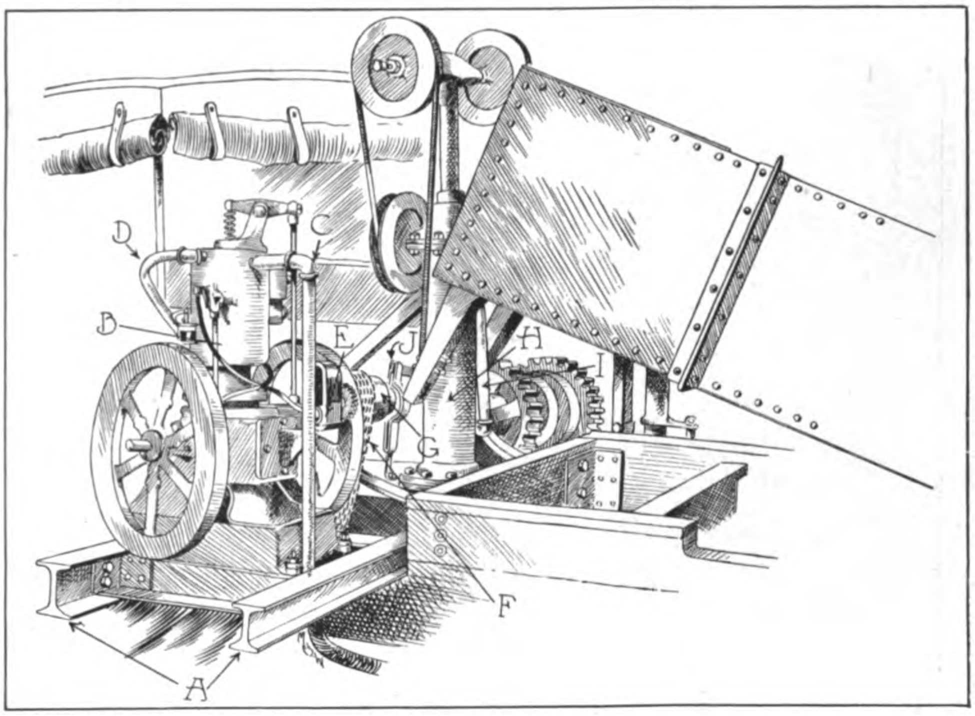
countershaft. When the lever is upright it is in a neutral position. Moving it backward will start the crane hoist and moving it forward will reverse it.

Carried beneath the frame at the right side is a centrifugal pump with capacity of 70 gallons a minute. This pump is driven by the auxiliary engine through a clutch on the engine shaft that drives a silent chain that couples it with the pump shaft. The pump shaft is transverse of the chassis and is above the main driving shaft of the chassis. The pump is fitted with a permanent funnel and a hand pump for priming, and two sections of hose are coupled to it, the one to the inlet, carrying a globe strainer, and the other a regular coupling. The pump is bolted to a cast steel cross member of the frame and is supported by truss rods that may be adjusted with turnbuckles. This prevents any possibility of damage from vibration. The pump is operated by a lever that is installed directly over it, so that the driver may work conveniently. All moving parts are amply lubricated.

The intention is that the truck shall always be worked with the right side to the curb or sidewalk. When driven to a basin the main engine is stopped and the auxiliary started. As the small motor can be driven at a constant speed, and the provision for cooling and lubricating are entirely adequate, no special attention is required. When the truck is moving the crane is locked so it will not swing. When the truck is located for work it is so that the crane will swing over the manhole. A lever at the base of the crane is used to swing the arm as desired, for with varying camber of street surfaces and the weight of the bucket this could not be conveniently done otherwise. The bucket used is of heavy metal and has capacity of about 1.60 cubic feet. When filled the bucket weighs about 200 pounds. As the bucket can be hoisted and emptied by a trip cord as quickly as it can be filled it will be seen that a great deal of time can be saved, the limitation being the shovelling of the one man who can work in the catch basin. When the work is done by hand small buckets must be used, for these must be drawn to the sidewalk by hand and then lifted to the height of the cart body and emptied. This of necessity is slow and hard labor. By the use of the pump a basin can be quickly cleared of water, and with the hydraulic hoist the body can be dumped in a very short time.

The truck can carry approximately three cubic yards of material. As many as 10 basins have been emptied in a day. The mileage is comparatively short, but about 15 miles daily, and yet the hauls are made with very little lost time for the men. The installation of the auxiliary engine minimizes the cost of fuel, for the main engine can be used merely for driving the truck and dumping. The auxiliary power is sufficient for all requirements. The small motor has been driven with kerosene, and it is probable that for next season this fuel will be generally, if not always, used for it.

The comparatively small mileage minimizes the cost of tires, the fuel expense is low, and the statement is made by the department of public works that the basins are cleaned for about two-thirds of the cost with horses, carts and hand labor. The truck body and equipment may be removed with the approach of winter and the chassis can be utilized with another body for other purposes.



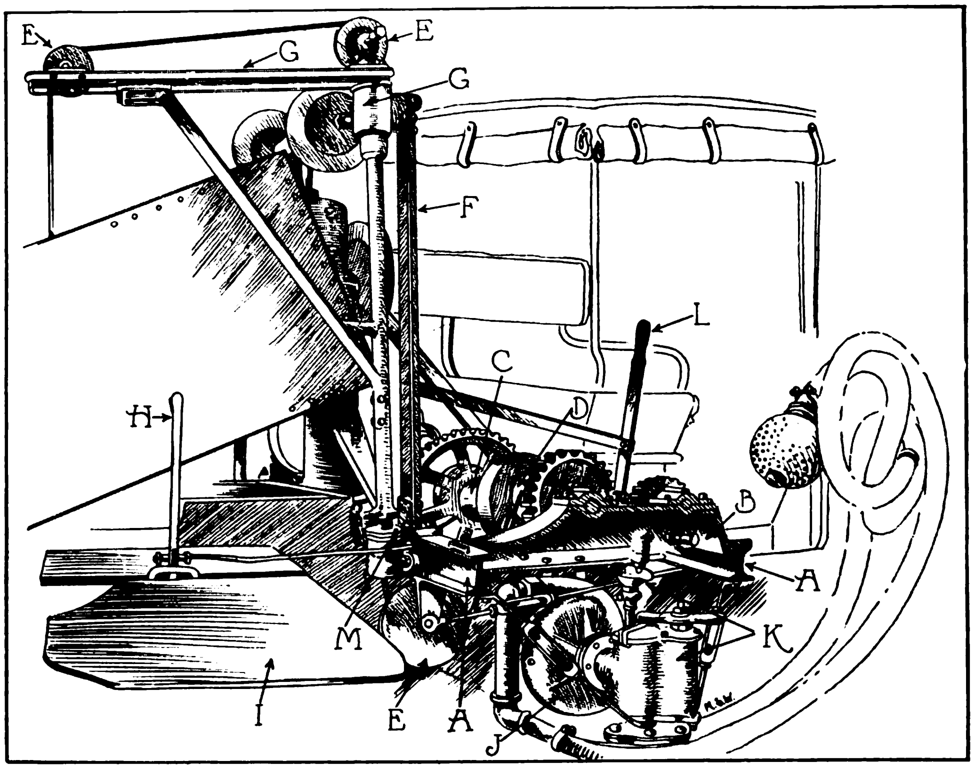
Catch Basin Cleaning Truck, Left Side, Showing Auxiliary Engine and Hydraulic Hoist: A, Frame Carrying Auxiliaries; B, Two Horsepower Two-Cycle Motor, Adjustable on Frame; C, Exhaust Pipe Connected with Main Exhaust Manifold; D, Water Outlet Connected with Rear Cylinder Unit of Chassis Motor; E, Bosch Low-Tension Magneto; F, Silent Chain Driving Water Pump Shaft; G, Water Pump Driving Clutch; H, Hydraulic Hoist Cylinder; I, Hydraulic Hoist By-Pass; J, Water Pump Clutch Lever Linkage.

The equipment was entirely experimental, the material was purchased in different places and patterns were made and parts cast and machined, so that while the work was done in the shops and at minimum cost, the expense of building was a great deal more than if the design were standard and the equipment produced in quantity. The expense was about $1500 above the cost of the chassis. As the city has a well equipped garage and shop, and competent mechanics, whose capacity may be judged from the construction described, it is expected that the life of the truck will be much longer than the average. As a practical, labor saving machine the truck has a great deal to recommend it to the attention of every municipality having similar work.

The utility of the truck and its equipment does not

appear unless one has some knowledge of the work and the possibilities for economizing. To illustrate, the supervision of the work is not now necessary. The driver of the truck is each day given a list of the basins that he is to visit, and these are generally grouped. When a basin has been cleaned a record is made of the material removed, which is measured in the body of the truck by a gauge stick, the capacity of the body having been determined by water measurements. And if, for instance, three basins are cleaned for a single load, the quantity taken from each is known, as well as the total. The truck carries the material to the dump, where a report is made of the work performed each trip. The daily and weekly report is made to the office of the department, and the record kept complete. The detail of operating expense is also recorded with care, and as the department has a number of motor cars and wagons to maintain in its garage the system of maintenance is well planned and is economical.

The experience has been that the cleaning of the basins is necessary in the spring, and in the event of a severe storm in some localities, but the belief of the department is that a great deal of the time of the truck can be devoted to haulage for the water department, and by removing the body and hoist and the installation of a platform it can be quickly converted. Where the requirements are greater than they are in Pawtucket permanent equipment might be desirable, but as there would be little difference in cost and no loss of efficiency, the convertible apparatus is to be preferred, for its utility for other service is preserved.



Right Side of Catch Basin Cleaning Truck, Showing Crane Hoist and Water Pump: A, I Beam Longitudinal Members of Equipment Frame; B, Cast Steel Cross Members of Equipment Frame; C, Countershaft of Crane Hoist; D, Crane Hoist Cable Drum; E, Grooved Cable Pulleys; F, Angle Steel Crane Mast; G, Steel Tubular and Angle Standard and Arm; H, Crane Operating Lever in Neutral Position; I, Folding Footboard; J, Water Pump; K, Water Pump Priming Funnel and Priming Pump; L, Water Pump Operating Lever; M, Crane Arm Lock.

HOLT TRACTOR WINS $15,000.

Sixty Horsepower Caterpillar First in Argentine Traction Engine Trials.

The Argentine Confederation government has stimulated agricultural machinery development and use by competitive trials held at different places in the nation for several years. The Holt Manufacturing Company of Stockton, Cal., and Peoria, Ill., won the chief 1913 honor, notification being given that concern by cable that the 60 horsepower caterpillar gas tractor entered by it in the Argentine Traction Engine Trials had received the award of the first prize.

The competition was this year at Magdalene, and the committee of awards was presided over by the Director of Agriculture, so that the event was in every way of national consequence. In the trials 12 tractors were worked, these being entered by American and European manufacturers, and the first four prizes were carried off by the American machines, while the fifth was awarded to a French firm. The importance attached to the competition may be judged from the prizes, the first of which was $15,000, the second $10,000 and the third $5000. This is the second year in succession that the Holt company has won this competition, and both years the Holt caterpillar has been regarded as superior to all others.

The articles defining the regulations of the contests specify that the purposes were "to determine suitable traction power for the economical future of the province; thus putting the farmer in the right drift for the purchase of such mechanisms as their industries require". The Holt caterpillar tractor this year won the traction engine contest at St. Petersburg, Russia, and so satisfactory was the showing that the Russian government immediately ordered two machines for military purposes. This was a very satisfactory recognition of the qualities established by the award of the judges.

J. R. Callum, who has been identified with the automobile industry and trade for eight years, has organized the J. R. Callum Company and established a place of business at 708 Granby street, Norfolk, Va. The company has the agency for Alco and Sanford machines, and also carries a line of tires and automobile supplies and accessories.

MODELS C AND CX ERGON MOTORS.

THE Hazard Motor Company, Rochester, N. Y., is now building three sizes of Ergon motors, the original production, having bore of 4.375 inches and stroke of six inches, being known as model D, and two new models designated as models C and CX, these having cylinder bore of 3.75 inches and four inches respectively, and stroke of 4.5 inches. Eight types of these three sizes are built.

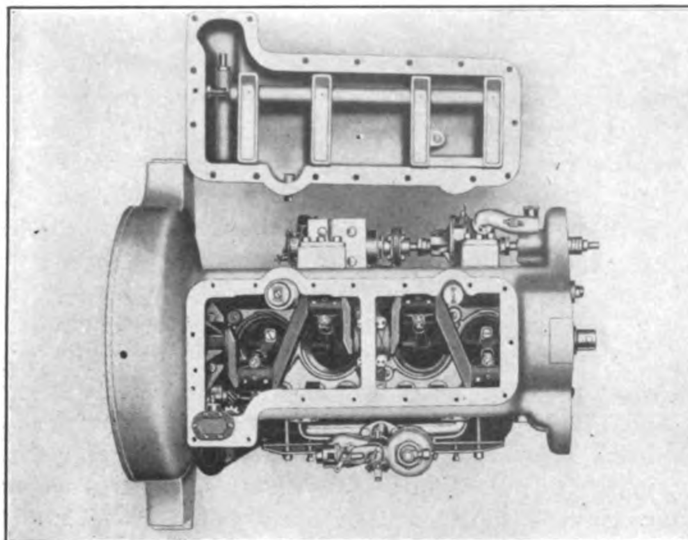
The new designs have numerous features, being exceedingly simple in construction, all working mechanism being fully protected. The motors are supplied as complete unit power plants, as single engines for main or sub-frame installation, or with flywheel and flywheel housing, so that any type of unit power plant clutch and transmission gearset may be used.

Accessibility has been carefully studied and the motors have been in every way simplified. By the removal of the oil pan, which can be done without breaking any connection aside from the removal of the oil strainer in models C and CX, the crankshaft and connecting rod bearings can be exposed. The front cover plate and the support for the starting crank can be taken off without removing any other part, and with the unit constructions the clutch and the gearset can be removed without taking out the motor.

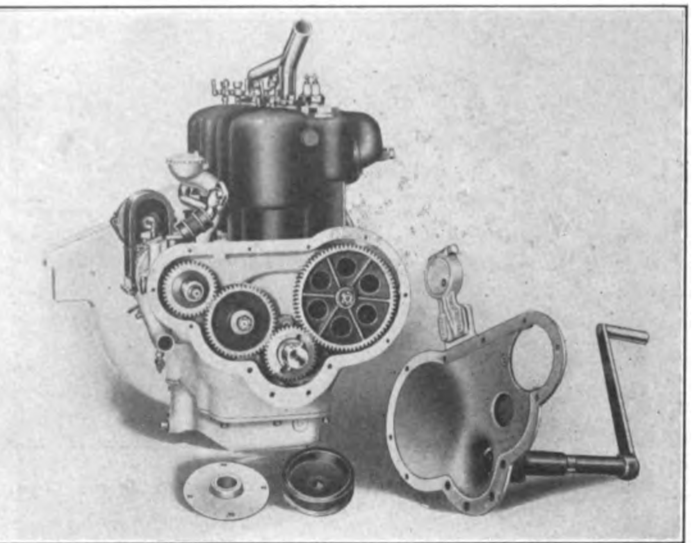
The cylinders are an L head type, cast in pairs, having liberal water jackets, and the units are cast with side and base webs at the valve sides forming pockets for the protection of the valve stems, springs and tappets. These pockets are covered with plates that are retained by wing nuts and are easily removable. The centres of the units have large openings for the caps that carry the water outlet manifold.

The cylinder units are bored, reamed and ground carefully to size and the pistons are turned and ground to accurate fit, so that these are interchangeable. The pistons are fitted with four rings, one of which is at the wristpin, the rings fitting into the ends of the pins and preventing movement, as well as sweeping lubricant into the hollow pin centre. The crankcase is a barrel type, cast from a special aluminum alloy, and the bottom is a cast iron tray or pan that is attached to the case by studs, nuts and lock washers. The use of the cast iron insures extreme rigidity and strength. At either side at the rear of the case are strong supporting arms cast integral with the flywheel housing, and suited for either main or sub-frame installation. With the model D the forward support is a trunnion that is fitted to a bracket carried on the chassis or subframe, but with the models C and CX the support may be the trunnion on the cover plate through which the starting crank is passed, or it may be a boss on the bottom of the front end of the crankcase, ahead of the oil pan. From the illustration the construction of the oil pan may be noted.

The engine has three long main bearings, the centre bearing being installed in a substantial transverse web. In these is carried the crankshaft, which is made of a high grade carbon steel drop forging having a tensile strength of more than 90,000 pounds. The shaft is carefully machined and ground. This is mounted in bearings that have a total length of 8.75 inches for both sizes of motor, and these are each secured by four bolts. The camshaft has also three bearings of liberal diameter and length, and is carefully finished. The crankshaft and the camshaft are carried on die cast babbitt bearings, save the forward end of the camshaft, which is on phosphor bronze. The connecting rods are drop forged from a high carbon steel and are heat treated. The timing gears are helical cut and are of wide face. The camshaft is driven direct from the timing gear of the crankshaft, but the countershaft is driven by an idler gear. The gears operate without noise at all times.



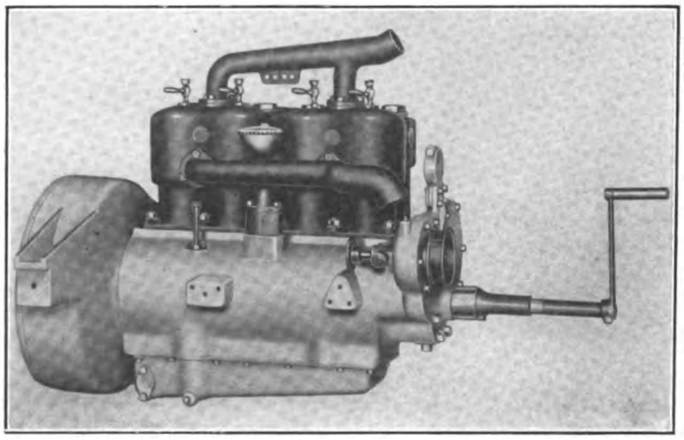
Bottom View of Model C Ergon Engine, Showing Oil Pan Detached.



Front View of Model C Ergon Engine, Showing the Timing Gears.

The valves are large and have a liberal clearance. They are made of cast iron heads electrically welded to carbon steel stems. The valves move in long bushings that serve as guides. The valve tappets are a mushroom type and are operated in guides mounted in the web above the base flange. The tappets are fitted with usual means of adjustment for wear. The lubrication is by means of a pump that maintains a constant level in the oil pits. The oil is pumped through a filter to these pits and the big ends of the connecting rods carry scoops that lift and distribute the lubricant to oil pockets that supply the main bearings and the timing gears, as well as lubricating all the bearings of the camshaft, the wristpins, the valve tappets, cams and the piston and cylinder walls. The quantity of oil in the reservoir is indicated by an indicating device that is visible when the hood is raised.

The cooling is by a circulation of water through the large water spaces of the cylinder units, by means of a centrifugal pump driven by the countershaft, the impeller being a hard die-cast metal that has great endurance. When thermo-syphon cooling is used the



Right Side of Model C Ergon Motor, with Manifolds for Thermo-Syphon Water Circulation.

motor is fitted with larger cast iron water manifolds that are sufficient to insure a free movement of the water. The water manifolds are of a special alloy of steam brass that insures a close grained casting that will be free from leaks. The intake manifold is of aluminum and the exhaust manifold is cast iron. Provision is made for mounting the magneto on a bracket at the right side of the motor, where connection is made with the countershaft by a flexible coupling, the magneto rotating clockwise. Both magneto and water pump may be easily removed should this be necessary.

Much care is taken to balance the motors. The flywheels are first tested off the shaft and again when assembled with the crankshaft. Each engine is tested under its own power and after the test is given an overhaul and again run for several hours. A very efficient and thorough inspection department is maintained, and all machined parts are inspected after each operation. Assemblies are carefully watched and great care is taken that the engines shall be sent out free from faults and imperfections.

The motors can be fitted with different carburetors and magnetos, and flywheels are supplied for all styles of disc and cone clutches. The model C motor is rated at 20-25 horsepower and the model CX motor at 25-30 horsepower. These motors are fitted with a centrifugal type of throttling governor that is contained in a connection that is mounted between the carburetor and the fuel intake manifold. A butterfly valve is contained in this connection that is operated by means of a rack and pinion, the latter being attached to the throttle disc. The governor weights and spring are mounted on the camshaft front gear, the motion from the governor to the butterfly valve being transmitted by a swinging yoke connected with the rack by a stiff steel rod. The action of the governor is positive and adjustment can be made when desired. The governor is not supplied as equipment, an additional charge being made for this.

HAULED 666,000 BRICK NINE MILES.

Hauling 666,000 brick nine miles may not appear to be a large undertaking, but the Frank S. Parsons Company, Northampton, Mass., making contract for this work, abandoned horses and made a profit in a single season that more than paid for the cost of the Reo two-ton wagon bought specially to do this job. The company made the contract to haul the brick from Northampton to Amherst, a distance of nine miles, and after consideration bought a Reo chassis. A platform body was built of rough scantling and boards in three hours at a cost of $6. Then the work was begun.

The wagon with the body weighed 4460 pounds. A load was made of 1250 bricks and four round trips were made each day, the total of 72 miles being covered daily for 133 days and two hours, when the last brick was delivered at Amherst. The average fuel used was nine gallons daily, and .66 quart of oil was consumed, which, at 30 cents a gallon for oil and 18 cents a gallon for gasoline totalled $1.82, and this, with the driver's wage of $2.50 a day, made the daily average expense of operation, aside from fixed charges and repairs and maintenance, $4.32.

Very accurate record was kept of the work done and the cost of operation and upkeep, because the company was desirous of learning what was possible, and because few persons believed that a machine could be operated as productively in this work as horses. The owners have found the wagon paid for itself with the brick contract alone, to say nothing of profit from other work done as demonstrations. The machine is now in daily use and has little evidence of a hard season's service.

Frederick E. Gooding has been made assistant manager of the truck sales department of the Willys-Overland Company of Toledo, O., and will have charge of the sales of the Willys Utility wagon, made at Lima, O.; the Garford trucks, made at Elyria, O., and the Overland delivery wagon, made at Toledo, O.

VALUE OF TIME IN HAULAGE SERVICE.

Record of Daily Work of Each Vehicle and the Cost, Afford Knowledge Through Comparisons That Make for Really Productive Transportation Economy.

WITH the study of transportation by highway vehicle the fact that vehicles should be worked as much of the time as is possible is more strongly emphasized. It is not a new condition, but it is the application of an old idea to work that has never before been regarded from the viewpoint that its importance demands. When the cost of haulage was generally unknown the possibilities of economy were never seriously considered, but there is no reason why the time of men and vehicles should not be conserved to the same extent as is labor and the use of tools, apparatus and facilities in manufacturing or in commerce.

The economy of time is sufficiently understood so that no argument need be made, but the demand that has made possible the enormous development of railroads, of steamship lines, or machine production, has been turned to highway haulage because of the greater speed and carrying capacity of motor vehicles as compared with animals. Those who have given thought to statistics and made estimates based on incidental observation realize that the cost of transportation is enormous, and that even the reduction of a very small percentage would be a saving that in the aggregate would reach an astonishing sum.

As the nation, the states and the municipalities and even individuals are contributing large amounts of money toward the improvement of the principal highways, and the cities and towns are constantly bettering the condition of streets, there is every reason why there should be some practical realization from the expenditures, and this cannot be done unless the roads and thoroughfares are used. There is no doubt that American highways are far from being the smooth and well built ways that are available for communication in Europe, but it must be remembered that European roads often represent the development of as many centuries as those of America represent years.

Europe developed through the building of highways. America constructed railroads as the principal means of communication. Now the construction and use of roads as a means of reducing the cost of transportation, at least between points within a reasonable distance, is evident. But the methods that were the vogue with animals are no longer practical. Time lost with a horse wagon or truck was accepted as a matter of course because there appeared to be no other form of conveyance, but when a motor vehicle is used the desire is to economize time. This is generally accomplished by overloading without a thought of analyzing the work and learning precisely what could be done or where saving could be made. Naturally, it is necessary to have record of what work is done. Many suppose that making comparison with horse work is sufficient to make judgment, but as a matter of fact such determination is about as uncertain as estimating from one figure or dimension.

The cost of horses, established by absolutely accurate accounting, would give a definite standard from which economy might be secured by careful attention to detail and by good administration. This has been the experience of some concerns that have large transportation departments. But there are numerous factors that must be considered before comparisons can be intelligently made. When these enterprises have changed to motorized equipment, the method in use, with such adaptation as might be considered to be necessary, has been continued.

Shevlin-Carpenter Lumber Company's Driver's Daily Report: Printed Both Sides in Black on Heavy Manila Card, 8.5 Inches Length and 4.5 Inches Width.

In the use of motor equipment the cost of any previous work by any other form of transportation is not a material factor. If there is doubt as to the possibilities a change is not well advised. But when motor vehicles have been bought the main purpose is to use them to the greatest advantage. This being so the time of the driver or crew should be divided. The period from leaving the garage to returning may be termed the service time, and the portion of that period that the vehicle is actually in motion may be termed the working time. Under the most favorable circumstances, unless return loads are carried, not more than half the working time can be regarded as productive time.

Assuming for the purpose of illustration that the

REPORT ALL STOPS OR DELAYS OF FIVE MINUTES OR LONGER.

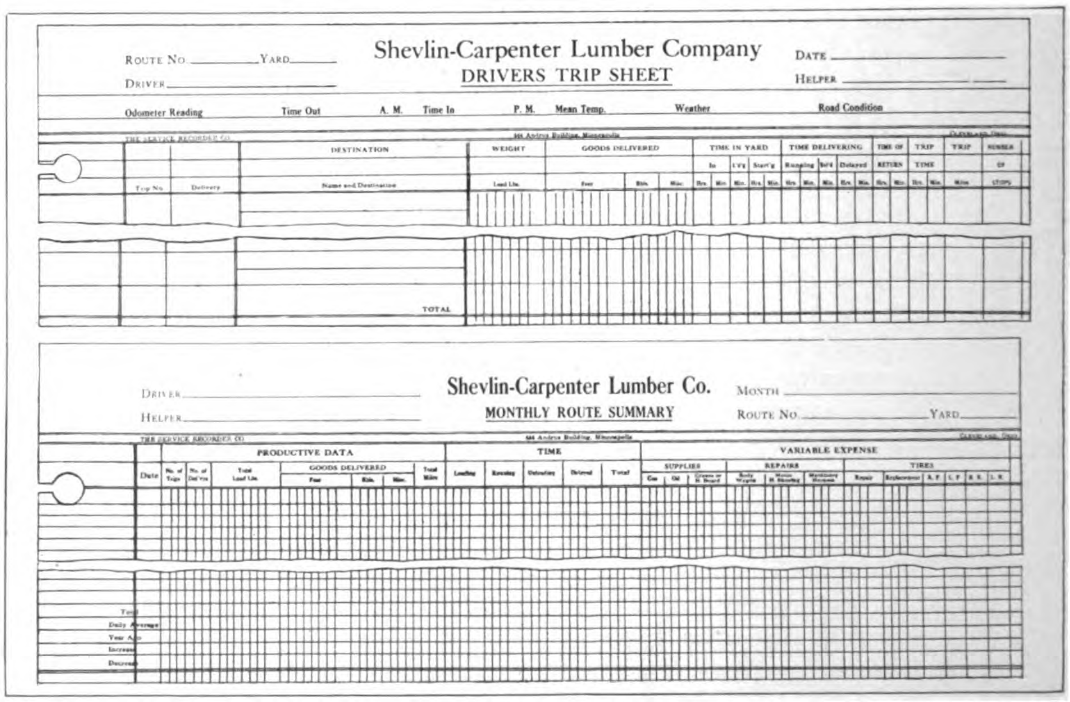
or trucks more or less removed from the store, warehouse, factory, shop, mill or yard, but whatever time is devoted to this form of travel is necessarily unproductive. This time must be included in the working time of the drivers and the period usually has limitations.

The form of record that is best adapted for any system is that which is, so far as possible, mechanical. The reason for this is that it will be uniform in its data and will always be dependable unless an accident should disable the instrument, and such interruption can be insured against by reasonable care in installation. The record should be sufficiently clear that the notes can always be read, and the chart or tape or whatever form the indication may be should be such that it can be conveniently preserved. The cost of records may appear to be considerable, and a system should be as simple as possible and yet supply the data desired. Methods that can be applied to operating cost and garage expense are comparatively easy to create, and these can be depended upon as reliable and satisfactory, but what is most essential is that which will differentiate the service and working time, and from which conclusions can be made that will yield practical economy.

service time of a day is 10 hours, and the working time is seven hours, there is of necessity three hours of idle time, and if the proportion of idle time can be decreased and the working time increased there is an economy that can be measured in money, for it is possible to determine very accurately the expense for a mile, day, week, month or year. The work, however, is much different than where an employee is under observation, as when working at a machine, and where production is accurately known. There are innumerable causes for lost time. It is not practical to enumerate these, but there are a number that have material bearing, and of these loading and unloading are particularly important. Loading can be governed, and it is possible to facilitate unloading, while delays in traffic, from accident, from engine faults or failures, from tire damage, from road conditions, and the disposition of the driver to make the most of his time, cannot be insured against. But it is possible to have a record of the human element involved and to establish responsibility to such an extent that there will be a minimum loss of time, and to direct the work so that the greatest results will be accomplished. This means a closer supervision and an analysis of time of both men and vehicle, and the character of the productiveness will depend largely upon the administration.

The location of the garage with reference to the place of loading is of considerable importance, for distance means unproductive work both going from and returning to the station, and as the number of machines is increased this item assumes greater proportions. There may be economical reasons for keeping the wagons

The Shevlin-Carpenter Lumber Company, Minneapolis, Minn., which uses a number of trucks in lumber haulage, has its vehicles equipped with Service recorders, and from the charts and with the reports of



Shevlin-Carpenter Lumber Company's Records: Upper Form, Driver's Trip Sheet, Printed in Black on Yellow Paper, with Ruling of Red and Blue, with Space for 11 Entries, 8.5 Inches Length and 14 Inches Width, Cut for Loose Leaf Binding; Lower Form, Monthly Route Summary, Printed in Black on Light Lemon Paper, with Ruling of Red and Blue, with Space for 31 Entries, 8.5 Inches Length and 14 Inches Width, Cut for Loose Leaf Binding.

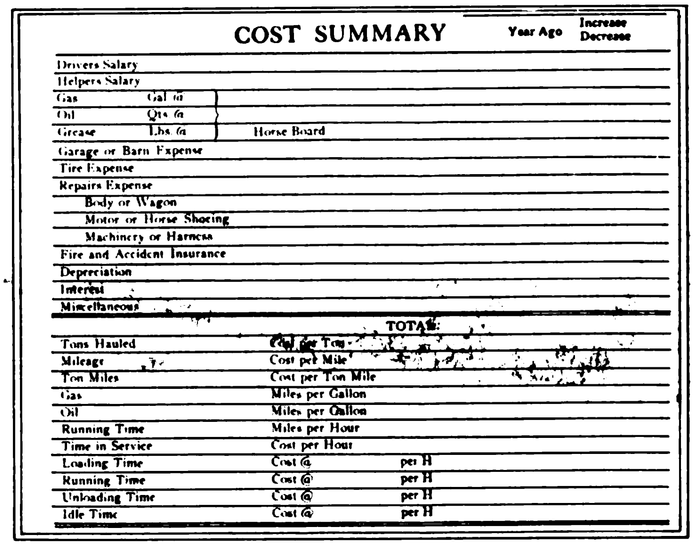
the drivers and the garage records it has at its disposal data that are extremely valuable for comparison, and from which the superintendent makes analyses and directs the administration of the department. The work, as may be assumed, is generally within a reasonable radius of the yards, and most of it is haulage one way, the returns being made without load. The drivers are assigned to routes wherever practical and they drive the same vehicles.

On leaving the garage in the morning, and most of the machines are kept at yard garages, a card known as the "Driver's Daily Report" is begun. On this is entered during the day the number of the route, the number of the yard to which he reports, the date, the names of the driver and helper, the time of leaving and returning and the net number of hours worked (eliminating time for meals, etc.,), the reading of the odometer at start and finish and the net number of miles driven, the quantity of gasoline, oil and grease supplied to the machine, the accidents or vehicle trouble experienced, and the names and addresses of the witnesses, if any, of accidents. The names of two witnesses are obtained. On the reverse of this card is entered a report of all stops or delays of five minutes or more, these being entered in rotation and by number, giving the time of stop and start, the place and the cause. It will be seen that this report will also include the time of loading and unloading each trip, and the times will coincide with the record made by the recorder on the chart. This report is turned in at the office of the garage at the end of the day.

It has no doubt been noted that this card contains many essential facts, but in addition to this the drivers fill what is known as a "Drivers' Trip Sheet", which gives the number of the route, the yard number, the date, and names of the driver and helper, the odometer reading, the time out of the garage in the morning, the time of return, the mean temperature, the weather and the road conditions. On this is also entered, for each trip, the trip number, the nature of delivery, the name of the person purchasing and where the load is to be delivered, the weight of the load in pounds, the goods delivered in feet, barrels and miscellaneous; the time of the vehicle in the yard in hours and minutes, the number of minutes loading and the time of starting the trip; the hours and minutes "running", the minutes making delivery and the hours and minutes delayed; the time of return, the time of the trip in hours and minutes, the mileage of the trip and the number of stops. The sheet has space for 11 entries and it is cut for loose leaf binding.

The "Monthly Route Summary" is a very comprehensive record. This is made up each day and shows the month, route and yard number, names of the driver and helper. Each daily entry is made under the following headings in columns under the general designation of "Productive Data": Date, number of trips, number of deliveries, total load carried in pounds, goods delivered in feet, barrels and miscellaneous and the total mileage. Under the heading of "Time" is shown the total time loading, running, unloading, delays and total. The "Variable Expense" is divided into "Supplies", "Repairs" and "Tires", and under "Supplies" is entered the cost of gasoline, oil, grease or horse board; under "Repairs" is entered body or wagon, motor or horse shoeing and machinery or harness; under "Tires" is entered the cost of repair, replacement and the wheel location, these being designated as right forward, left forward, right rear or left rear. When this sheet is totalled the daily average for each column is found and below it is entered the average for a year ago, and the increase or decrease.

On the reverse of this sheet is entered the cost summary, and this includes the driver's salary, helper's salary, gallons of gasoline and the price, gallons of oil and the price, pounds of grease and the price, horse board, garage or barn expense, repair expense divided into body of wagon, motor or horse shoeing, machinery or harness; fire and accident insurance, depreciation, interest and miscellaneous, these being itemized. Against this column are set the items for the



COST SUMMARY — Year Ago — Increase / Decrease

Idle Time	Cost @	per H	

Reverse of Monthly Route Record, Printed in Black, Providing for Comparison of Cost for Any Month of Record with That of the Same Month of the Previous Year.

same month of the previous year, and the increase or decrease shown. Two columns are totalled and the increase or decrease in the yearly comparison indicated.

On the same form, below, is entered the tonnage hauled and the cost per ton, the mileage and the cost per mile, the ton-miles and the cost per ton-mile, and total gasoline consumed and the miles per gallon, the oil used and the miles per gallon, the total running time and the average miles per hour, the time in service and the cost per hour, the loading time and the cost per hour, the running time and the cost per hour, the unloading time and the cost per hour, and the idle time and the cost per hour. As with the first tabulation, the items are compared with those of the previous year and the increase or decrease shown.

In this summary results are shown in an exceedingly simple manner. The comparison of the cost is obtainable from the driver's report and the trip report for

practically every item save the four fixed charge items, insurance, depreciation, interest and miscellaneous, but included with these usual statements is the service time and its analysis and the cost, and a definite means of comparison.

With these summaries it is possible to make comparison of different vehicles, to make further analysis by the day or for any given period, and to learn just what proportion of the time is used for productive work and the proportion and cost of the idle time.

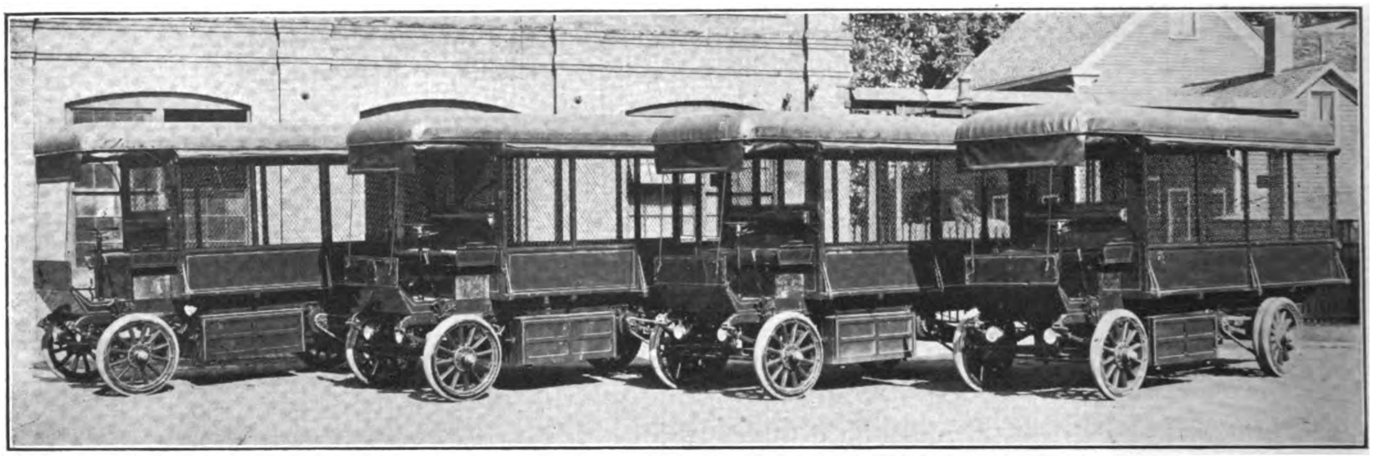
The record is not complicated. Practically everything necessary in connection with its use is shown in the forms that have been reproduced, and examination will demonstrate that these may be adapted to practically any system with the addition of some form of recording instrument that will supply the data relative to the time. It is evident that with a working day of 10 hours the time of a truck and its crew at $12 is two cents a minute. If the truck is in service 10 hours and its working time is six hours and 40 minutes the time is worth three cents a minute. The working time must pay for the idle time. If the working time can be increased the cost of the work is correspondingly decreased, and as there is but little cost, aside from fuel and tire, for this added working time the gain is decidedly important.

CONSTANT SERVICE WAGONS.

New York Edison Company Adds Four Baker Two-Ton Machines to Its Fleet.

The New York Edison Company, which serves the island of Manhattan and the Bronx of New York with electric current for light, power and heating, provides a service that must be continuous, and which requires the maintenance of a part of its transportation equipment so that it will be available practically at all times. The department is extremely well organized and a surprising volume of work is done with the fleet of electric machines that it utilizes, but the majority of the wagons and trucks are used during the day, the remainder being in service for trimming and patrolling. Electric vehicles can be driven constantly, aside from the time necessary for charging the batteries, and with a view of economizing garaging space, which has become a problem of no small proportions, and of minimizing other expenses, the company has made provision for making battery changes which will make the machines available at all times during the day or night by simply exchanging the batteries.

The greater part of the equipment is fitted with side loading battery boxes, although some of the wagons and trucks have boxes that are loaded and unloaded from the bottom. It is probable that these will be eventually changed so that they can all be loaded from the bottom, and to this end the garages have been fitted with pneumatic lifts. These lifts are located where the wagons can be driven over them, being in pits with platforms that are level with the floors. The batteries are taken from the battery rooms, where they are charged, on small hand trucks, and moved from the trucks to the lifts. By these lifts they are raised into the battery boxes of the machines, and when at a sufficient height they are held by automatic catches that retain them until released.



Four Two-Ton Baker Electric Wagons, Equipped with Bottom Loading Battery Boxes, in the Service of the New York Edison Company.

The company originally used lifts that were operated by hand pumps, and which required more time than was desired to raise and lower the batteries, and while these were efficient there was objection to the time required. With lifts operated mechanically the batteries can be quickly lowered or raised and an exchange made in very short time. All of the machines the company is adding to its fleet are equipped with the bottom loading battery boxes, this form of equipment being a feature of construction of the four Baker two-ton electric wagons that were recently added to the department. The company now has nearly 125 vehicles in its transportation department service, most of which are electric, and by exchanging the batteries these may be used practically the 24 hours, and the charging of the spare batteries can be done at any time. The arrangement also minimizes the charging equipment for the garages, as under the usual plan of operation from five to eight hours is necessary for energizing the batteries to the capacity desired.

MOTOR DELIVERY OF BOTTLED GOODS.

Pureoxia Company Minimizes Expense of Distribution in Boston and Suburbs, and Realizes Material Profit from a Limited Public Service at Its Garage.

THE business of the Pureoxia Company, Boston, Mass., is the manufacture and distribution of non-alcoholic beverages, which are bottled and delivered either to dealers or families. The company has been established for a number of years and its plant is located in Back Bay at Whipple and Norway streets. The success of the enterprise depends very largely upon its method of distributing its products, and as the demand increases or diminishes with the variations of temperature it is evident that the greatest volume delivered is during the part of the year when the temperature is high.

The company is well known and its beverages are standard in Boston and suburbs, where daily distribution is made. The plant is of considerable size and it has been equipped with every facility for the production of high quality products, the purity of which is emphasized. The greatest attention is given to sanitation and cleanliness in the plant, the different beverages are carefully bottled, attractively labelled, and are carried in substantial crates. The appearance of the crates and the bottles is regarded as being highly important, and the delivery is made by vehicles that are extremely well kept. The advertising value of the transportation department of the company is unusually large, because this is a means of keeping before the public a quality of production that has been established and is widely known. The company has spent money liberally for publicity and its reputation is a very large asset.

The Pureoxia Company has made no endeavor to extend its business beyond Boston and its immediate suburbs, and a radius of 15 miles from the plant is the longest distance that is traversed in a direct line, but in an area that has a population of more than a million people there are abundant opportunities for increasing sales. And for a business of this character the expense of distribution is proportionately so large that concentration of custom is more profitable than to develop customers at greater distances. That is to say, experience has taught that the more concentrated the given volume of business the more productive it is.

For a number of years the delivery was by horse equipment, but in August, 1911, the first motor wagon was purchased, this being a three-ton Rapid gasoline machine that was used for general delivery in sections that were then served by horse wagons, and to customers who were so far distant that they could not be afforded the service that good business demanded. The wagon was bought at a time when the demand was at its height and for that reason it was worked with a view of relieving the horse equipment, and when this had been accomplished attention was given to the custom that could not be well cared for without working the animals harder than good judgment would permit.

The Five Two-Ton General Vehicle Wagons Used by the Pureoxia Company, Boston, Mass., for General Delivery in That City and Suburbs.

The result of the use of the Rapid wagon was that a two-ton General Vehicle wagon was ordered for route service, and was delivered in December, 1911. The company had not begun motorization without considerable knowledge of the work that could be done, the limitations of the vehicles, the care and attention required, and the changes that were necessary to insure efficient operation. At Norway and Whipple streets was a two-story building in which a public garage was located, the business having been established several years and having a profitable custom. The property was purchased and the garage passed into the possession of the company, and the business was continued. In the garage was kept the Rapid wagon and, when the electric was received it was also stored there, a charging panel being added to the equipment.

The property was acquired for several reasons,

among them being the need for expanding the plant later on and that the limitations of the building then occupied had been reached, that the basement and second floor afforded excellent storage, and it was available for garage use without incurring expense. As the purpose was to conduct the garage and to make it self-sustaining, if possible, the business was maintained separately, and it has not appeared in the bookkeeping as a liability or an asset, but has existence entirely apart. Two two-ton electric wagons were bought early in 1912. These were, with the other electric wagon, used practically for route work. Of course these were assigned to the sections where the horses would be worked very hard, especially in the warm weather, but a great deal of the delivery was done by animal wagons.

With horses routes were in some instances as those covered by the electric wagons, but in some instances the animals were changed at noon, and in others they were worked every other day or five days a week, the use being governed by circumstances and the volume of work. The routes were made up for horses with reference to the load that could be carried. As the wagons took out loads of crates of filled bottles, and usually picked up a crate of empty bottles for every full crate delivered, a load was carried all the time. An empty crate weighs about half what a filled crate will weigh. As the crates and bottles are valuable and as they could be collected when delivery was made, without much loss of time, it will be understood that long mileage meant very hard work for horses, and that from one point of view all of the work done was productive. This explanation is made to emphasize that this work was equivalent to carrying 75 per cent. of the load the entire distance, as against carrying a full load half the distance, which is the usual experience with haulage. Before motor wagons were purchased 11 wagons were in service, and at least an extra horse was required for each pair.

The result of the first full year's work with the Rapid wagon and the three electrics was that two more electrics of the same size and make were purchased and also an Autocar wagon, these being delivered early in 1913. With these the number of horses was decreased, and but one has been purchased this year, and the horses now number six in all. During the summer, when the business was the heaviest, extra horses were hired whenever necessary. This was an annual experience, but the number hired this year was smaller and for a shorter period than ever before, the machines taking care of much of the excess business without overworking their crews.

There is little probability that horses will be used after the coming winter. Several wagons will be added to the equipment and next spring the delivery will be made by motor vehicles. With the present system each wagon covers a route and only orders are taken out. The driver does the loading and the delivery, and collects the empty crates and unloads them on his return. During the period of the year when the most business is done each wagon will carry about 100 crates to a load, and in some instances more, and generally to deliver and collect 100 crates is a day's work. Under some circumstances extra work is required, or special trips are made, but only during the extreme height of the summer business.

The electric wagons are used on route work practically all of the time, but the Rapid wagon is occasionally worked on special haulage aside from the routes. The Autocar wagon is sent over a route that includes widely scattered customers in a number of the suburban towns and cities, and in addition it makes trips to deliver special orders. The mileage of the Rapid wagon will range from 30 to 35 daily, the electrics from 23 to 30, and the Autocar will run up to 90 miles during the busiest season of the year. The average of the machines will be 27 for the electrics, 30 for the Rapid and 65 for the Autocar.

All the machines are kept in the garage, where they are washed, cleaned and polished each day, this work being done by the garage employees. The drivers oil and grease their machines and fill the tanks and make replenishments for the gasoline machines, but the batteries are charged at night by the man having charge of the garage. A spare battery is kept at the branch of the battery maker and this is known to be in good condition. In the event of a battery requiring attention an exchange is made and the battery taken out is immediately restored to its normal efficiency, this being done by experienced men and to the standard of the manufacturer. In this manner the maximum of battery efficiency at minimum expense is assured. The garage is in charge of a foreman at night, who looks after the charging, and he has two men who do the washing and polishing. There is usually but one man on duty during the day.

No repairing is done at the garage. There is no machine tool equipment, and the hand tools are generally those supplied with each machine. A few essentials for the electric machines are kept in stock, but a very good supervision is given by the service department of the manufacturer, and if parts are necessary these can be quickly procured. The Autocar is inspected weekly at the service station of the maker, and attention necessary for the Rapid machine is afforded at the General Motors Truck Company's service station.

When the garage was purchased it was giving service to about 25 customers, and at the end of the first year the books showed that it had paid six per cent. on the investment (the money invested in the garage property), and in addition had taken care of the machines of the company at practically no expense to it. This did not consider the actual value of the property to the company for expansion purposes, nor the probable increase in valuation, for property where this is is rapidly increasing in price.

Because of the reduction of the number of customers of the garage the present year to accommodate the seven machines, it is probable that there will not be as

good a showing financially as when the company owned a less number, but with the expense of the vehicles proportioned there will be a very small expenditure for garaging as compared with what might be expected under the usual conditions. But there has been no charge for administration of the business, this having been assumed by the manager in addition to his other duties. The service given at the garage has proven very attractive to the customers and a much greater volume of business could be done were there greater storage facilities.

The majority of the vehicles kept at the garage are gasoline, and aside from the charging panel no additional equipment has been installed. The drivers report at the garage about 7 each morning and after awaiting until the orders received in the first mail are loaded, they are sent away from 7:30 to 7:45. Some of them are absent the greater part of the day and others return one or more times. When horses were used the men were often delayed until 10 before starting, and they were correspondingly late returning. The routes were covered both winter and summer because of the necessity of working the horses during the period when business was light, and there was practically as much help necessary at all times of the year. With the motor equipment it will be possible to combine routes and withdraw a machine from service whenever this may be deemed practicable, and this will afford an economy that would not be possible with animal vehicles.

The machines are fitted with Jones recorders, and these afford a daily record of the time in service, the mileage, the speed, the number of stops and duration of stops, the actual time driven, the idle time and the time required for loading and for delays. Most of the machines are loaded before being sent to the garage for the night and the bodies are jacked to prevent damage to the springs. As the attention in the morning is confined to oiling, greasing and replenishments of fuel, water and lubricant for the gasoline truck, there is no need of delay. A record is kept of the mileage of each machine, the number of cases taken out and the number of empty cases returned, and this makes possible an estimate of the cost of delivery by case, but this entails an estimate of the cost of vehicle maintenance because of the conduct of the garage as a separate business. A record is kept of the gasoline, oil, grease, repairs and electric current required by the day and month, and for the year. The record of the tires shows the make, size, cost, mileage and adjustments. A third record is that of painting and general repairs, which may be regarded as an annual overhauling expense.

The accounting is simplified, there being nothing required in the records that is not essential. Special forms are not used, books being adapted to meet the requirements, and these may be continued for several years without renewals. When the books are filled they are permanent records and are always available.

The manner in which this company utilizes motor equipment is unusual, but it is an excellent illustration of what can be accomplished by a business man who seeks to improve his distribution methods. It is explained by the company that it is hardly practicable to state just what economy has been accomplished, because the business has been increased somewhat and comparisons are difficult to make when there are so many variable factors, but even if there has been no actual saving of money the delivery has been so much improved that there is a distinct gain in this respect and a decided promotion of the business.

ADEQUATE WARNING SIGNALS.

The owners of motor vehicles have found from experience that their drivers have to deal with people who, from carelessness or ignorance, invite or brave danger. In cities and towns where the traffic is congested and the streets much traversed there is necessity for warning signals that shall be sufficiently clear in tone to be heard above all other noise when sounded. The public can safely assume that the owners of trucks and other vehicles do not demand that their drivers endanger the public. To the contrary they insist that every precaution be taken and care observed. The fault lies largely with those who either do not regard warnings, do not hear them, or do not realize the possibilities of carelessness.

In large cities children play in the streets and are seemingly indifferent to consequences. Perhaps they have confidence in their own judgment to avoid danger and do not judge the speed or the distance, or overrate their own abilities to move quickly. The bulb horn signal may be heard reasonable distances when there are not other sounds, but what is apparently necessary is warning that cannot be misunderstood, such as may be given with a horn that can be operated by the pressure of a finger or the toe, such as a Klaxon.

The supposition may be that a warning signal is obnoxious from the volume of sound made, but the public is rapidly awakening to the fact that there must be a distinct and positive sound made that will be understood by all people alike. Those who do not see or hear well may be careful, but failure to act when danger threatens is a cause that no doubt results in injuries and perhaps fatalities. Public sentiment changes quickly, and in many municipalities where the Klaxon or similar horns were frowned upon the authorities are realizing that they are one of the best safeguards that can be procured and are now insisting that such signals be given.

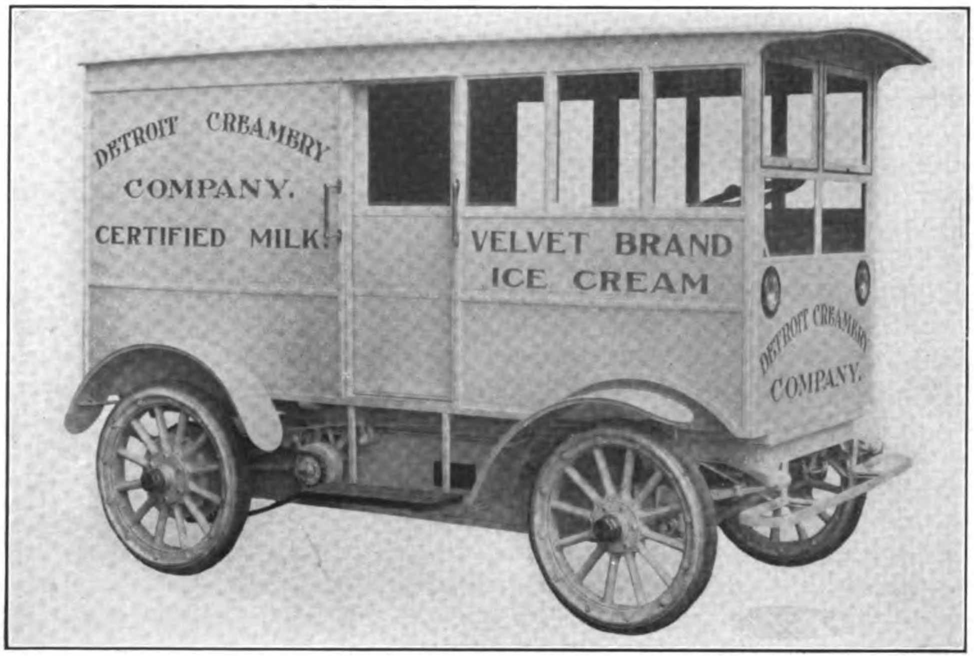
Signals that are adequate are not only a protection for the public, but they protect the owners and the drivers as well, and when these can be given instantly and can be heard plainly, there is no doubt whatever that the only other element to be dealt with is that of sheer carelessness or indifference. This can only be guarded against by placing some responsibility upon the public, but the driver must have the means for making satisfactory signals before this can be done.

SANITARY MILK DELIVERY.

Special Equipment Designed for Service Among Aristocratic Detroiters.

Cleanliness and assurance of quality is one of the best assets of a business man, and with the distribution of dairy products it may be said that appearance of the vehicles is one of the chief recommendations to customers. Sanitation is not a fad, but it is recognized as a necessity with those who would conserve their health. Milk is a standard food, and is consumed in increasing quantities the nation over, and concerns distributing it regard the appearance of their vehicles as exceedingly important.

An example of the endeavor to eliminate animals and to insure purity, as well as serve customers in a wide area, is that of the Detroit, Mich., Creamery Company, which is using a one-ton Detroit electric chassis, equipped with a special body for a route in Grosse Pointe, a suburb 11 miles from the centre of the city, where the majority of the residents possess wealth and demand the best that money can procure. The principal feature of the machine is its appearance.



One-Ton Detroit Electric Wagon with a Special Body That Is Designed for the Sanitary Delivery of Milk.

The body is a box type, with sliding doors at the centres of the sides, the forward half of which is built with a half panel front and two-thirds panel sides, the upper sections being fitted with fixed glass windows. The front of the body is practically a continuation of the dash, and the frame is carried upward with two intersecting members, dividing the space above dash and between the corner posts and the roof into four sections. In the two lower sections are two fixed windows, but the upper have two hinged windows that lift inward and are secured by catches to the roof. The roof extends forward beyond the windows, affording protection against sun and rain. In the upper parts of the doors are windows of the same size as those in the sides. The sides and rear of the body back of the doors are solid panels.

The body is plain, save for a line of molding that extends the length of either side about a third of the height. The material is selected wood, and endurance is insured by the protection of the sills and the side risers with copper sheathing to prevent decay of the wood and to minimize cleaning. The interior is arranged for the purpose of carrying the milk in bottles and to prevent breakage. The wheels are protected by short curved mudguards, and above the forward wheels the body is recessed to provide for clearance when the wagon is loaded. Instead of running boards there is a wide step at either side below the door, carried on heavy brackets. Forward of the chassis frame is a substantial bumper to protect the front of the body. There is little metal work, aside from the hand rails for the doors and the inset dash lamp frames. The interior of the body is lighted by dome lamps. The wagon as it is equipped is a development for practical service and it has appearance that will attract attention wherever seen. It is equally well adapted for all seasons, and affords every quality for protection against storm or dust, and it can be readily cleaned and ventilated. The interior is arranged for carrying milk in bottles or in large containers, and the load can be handled with minimum labor.

The body is painted with white vitrolite, which does not require varnishing, and does not yellow with age. The lettering is with gold leaf pencil varnish. The windows are plate glass.

The wheelbase is 84 inches and tread 58. The forward tires are 32 by three inches and the rear shoes 34 by 3.5 inches. The speed of the machine is 12 miles an hour and the mileage with a single charge of the battery of 60 Edison A-5 cells is 55.

The statement is made by Martin L. Pulcher, general manager of the Federal Motor Truck Company, that Federal machines are used in no less than 120 different classes of business, most of them being standards of industry or commerce, but some have been adapted for purposes that seem novel and unusual. Federal machines are used in Alaska, Cuba, Porto Rico, the Philippines, South America, Australia, India and Portugal, and the list of foreign countries is rapidly growing.

UNITED STATES BUREAU OF MINES RESCUE WAGON.

THE United States Bureau of Mines has stationed at Pittsburg, Penn., a special miners' rescue wagon that is specially fitted with equipment that is desirable or necessary in the event of a mining disaster. This vehicle is regarded as being the most scientifically developed apparatus of its kind in the world, and it is hoped that similar machines will be built and located in mining districts where they can be used for saving life. This wagon is government property and was designed with a view of carrying every form of apparatus that could be used in rescue work, in resuscitation, in affording relief to the injured, and having the speed to respond to a call in very short time.

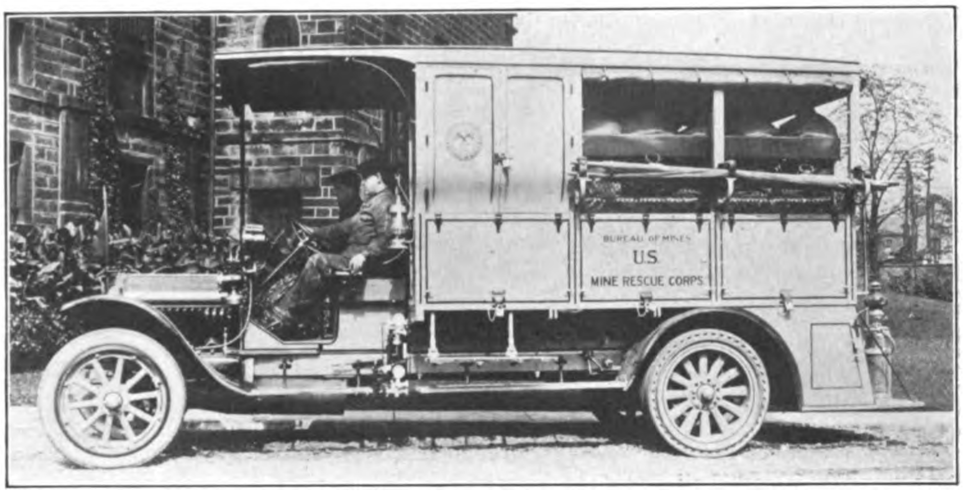
The machine is a White chassis on which is installed a body built to specifications furnished by the government, and with provision for carrying its equipment so that all may be instantly available and no time may be lost whenever there is need. In general appearance the body suggests an ambulance, or police patrol wagon, but this is dispelled when the machine is examined, for every inch of the body is given over to compartments for tools, instruments and apparatus, and these are accessible generally from the exterior, so that the driver or any of the crew may be able to find whatever is required almost instantly, even in the dark.

The machine was shown for the first time at the convention of the American Mine Safety Association, and so great was the approval and so apparent the utility of the apparatus, that it is probable that a number of others will be ordered and stationed in different sections of the country where mining is extensively carried on. For a demonstration a call was made, such as might result from an explosion, during the convention and the vehicle and its equipment shown to those present.

It is proposed by the Bureau of Mines that mine owners establish stations and provide them with similar equipment. The body was built with many compartments for carrying the tools, instruments and utilities which might be used in the event of a mine explosion. Beneath the driver's seat are two Draeger reviving outfits and under the body on a sub-frame are six oxygen tanks, stored transversely of the frame, that they may be readily withdrawn. The oxygen pump is at the left side of the chassis and is driven by the motor. At the back of the seat is a five-foot crowbar and tent poles.

At either side of the body are compartments opened from the outside in which are carried a tent, 22 feet of rope, three miner's picks, three miner's shovels, a four-pound sledge and two axes. Between these are two longitudinal seats with folding lazybacks, protected by a brass rail. Beneath these seats are compartments, and there is another under the rear steps with side and end doors. There are also shallow drawers that contain saws, hose coupling, reducers, spanners and 200 feet of half-inch rope. At the sides of the body in central compartments are a lifeline reel, a telephone system, compasses, bits, braces, chisels, hacksaws and blades, snatch blocks, and suspended outside of the body are two stretchers, fire extinguishers, lanterns, axes, and other tools. On the running boards are two special boxes that contain mine lanterns, and in addition the equipment includes a pump, two first aid boxes, 50 regenerators, two pulmotors, a box of explosives, a full telephone outfit and even a caged bird, the last mentioned being taken into mines to detect poisonous gases.

It will be noted that the machine carries everything that might be used in entering a mine where there is fire or gas, that when necessary a field hospital can be extemporized, and with the equipment a rescue corps can accomplish work that would under ordinary circumstances be almost impossible because of the lack of facilities that experience has taught are absolutely necessary in an emergency.



United States Bureau of Mines Rescue Wagon, a White Chassis, That Is Fitted with Special Equipment.

The Wagenhals Motor Car Company, Detroit, Mich., maker of three-wheel machines especially adapted for delivery purposes, has increased its capital from $100,000 to $500,000, and William Pflum has been elected president, W. G. Wagenhals vice president and treasurer, and Hughes G. Turner secretary. The company is to establish itself in Detroit in a plant that will permit the production of 3000 machines a year.

The Glyco bearing is being marketed by Joseph T. Ryerson & Son, Chicago, and it is claimed that by a bronze or steel reinforcement of skeleton construction the body and flange are greatly strengthened.

LIPPARD-STEWART NEW WORM DRIVEN CHASSIS.

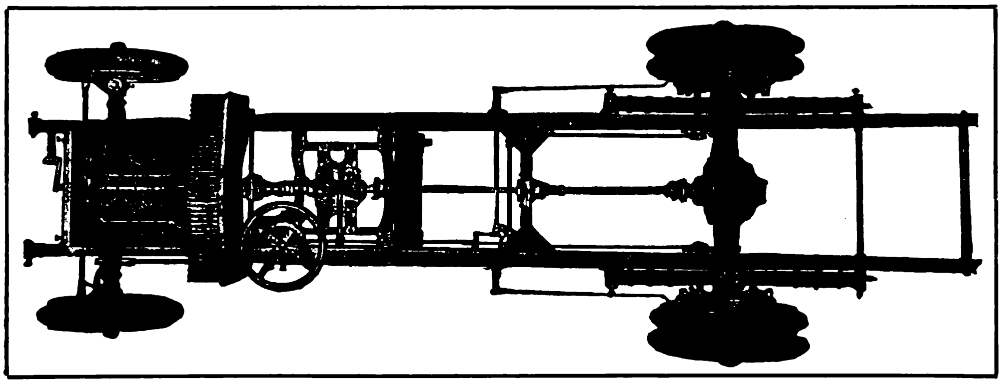
THE Lippard-Stewart Motor Car Company, Buffalo, N. Y., which, since its establishment, has specialized on the production of a 1500-pound delivery wagon chassis, which is marketed with six standard forms of body, has begun the manufacture of a 3000-pound wagon chassis which will be standardized, and which will be produced according to demand. This machine differs from the smaller in that it is driven by a worm and wheel power transmission system, but in general characteristics it follows the design. In the chassis is incorporated such refinements as experience has proven are desirable.

The Continental motor is a four-cylinder, water-cooled, L head type, with cylinder bore of 4.125 inches and stroke of 5.5 inches, which it is claimed will develop 35 horsepower at 1200 revolutions. The cylinders are cast en bloc, provision being made for enclosing the valve stems and springs. The crankshaft is carried on three long main bearings. The engine is controlled by a governor of centrifugal type, connected with a valve in the intake manifold, and operated from the pump shaft. The characteristics of the engine are well known, it being fitted with a float feed carburetor and a high-tension magneto. The cooling system is absolutely reliable. All parts of the motor are easily accessible for inspection or work.

The power plant is mounted in the chassis frame at three points, the forward end being carried on a trunnion, with side arms at the rear extending to the frame side members. The bearing of the forward trunnion is of bronze and a grease cup is provided to insure sufficient and positive lubrication. An Eisemann magneto with fixed spark simplifies the ignition system and eliminates hand control, while to afford a satisfactory fuel the carburetor has separate high and low adjustments, and the gasoline supply may be regulated by a regulator on the dash. The radiator is built with cast aluminum tanks and finned copper tubes, through which the water is circulated by a centrifugal pump. The radiator tube is installed in two groups, which may be quickly removed or replaced by others in the event of damage. The radiator is mounted on spring supports. Radiation is promoted by a circulation of air caused by fan blades attached to the rim of the flywheel. The engine is lubricated by a combination force feed and splash system, the oil being circulated through a system of tubes to the main bearings by two plunger pumps, and to the timing gearcase, the drainage filling the pits into which the big ends of the connecting rods dip. The oil is filtered and is used continuously. The quantity of lubricant in the reservoir is indicated by a sight gauge.

The clutch is a pressed steel cone faced with leather, beneath which springs are installed to insure ease of engagement.

The transmission gearset is a selective type, having three forward speed ratios and reverse. The gears have inch faces and the heavy shafts are mounted on roller bearings. The main driving shaft is in two sections, the rear end of the forward half being carried on a self-adjusting ball bearing mounted on a frame cross member, this construction eliminating all side pressure, and when the chassis is loaded the driving shaft is practically in a straight line. There are three universal joints, one back of the gearset case and one at each end of the rear section of the driving shaft.



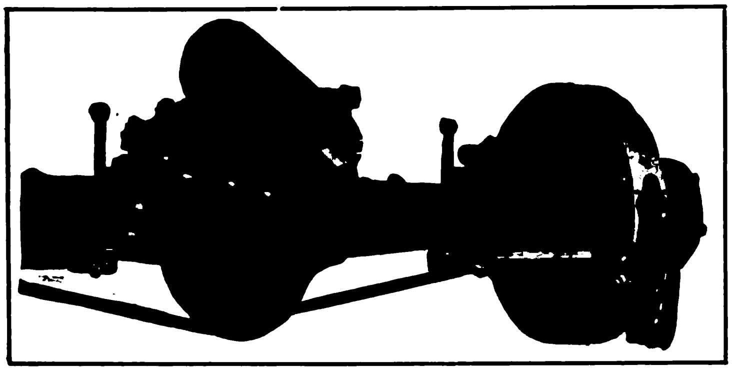
The Plan View of the New Worm Driven Lippard-Stewart 3000-Pound Wagon Chassis.

The rear axle is the Timken-Brown full floating type, the housing being in three sections, the centre containing the differential and the worm shaft and worm wheel, and to this centre the tubular ends are bolted. The housing is strongly ribbed and trussed. The worm shaft is steel and the worm wheel of bronze. Timken roller bearings are used throughout. Lubrication of the worm shaft is by troughs in the housing that carry the oil as it is distributed by the centrifugal movement of the gear wheel. By means of cleaning holes the worm, gear wheel and differential may be washed when necessary. The front axle is an I section steel forging with a solid rectangular centre reinforcement. The wheels and steering knuckles are mounted with Timken bearings. Both sets of brakes operate on the rear wheels, the service brake shoes being of the external contracting type applied through an equalizer, and the emergency brake shoes are expanding. The brake drums are 17 inches diameter and 2.75 inches width.

The drive is left side, the steering gear being of the worm and gear type, the drag link connections with the steering knuckle arms having ball and socket joints, with spring buffers. The hand wheel is 18 inches diameter, with the throttle lever mounted on the steering column.

The wheelbase is either 145 or 158 inches as desired, and bodies of 10 and 12 feet may be installed

without overhang. The load is so distributed that 30 per cent. is carried on the forward wheels and 70 per cent. on the rear wheels. The chassis frame is 6.0625



The Rear Axle Construction of the Lippard-Stewart 3000-Pound Wagon Chassis.

inches width channel section of 4.25 inches depth and .25 inch thickness, and is alloy steel. The forward member is hinged so that the power plant may be readily withdrawn on skids when desired. There are four other cross frame members, that at the rear being a tubular tierod. The frame at the forward end is "necked" to insure short turning radius.

Following the design of the smaller machine the motor is carried forward of the radiator and under a sloping hood, which may be lifted on hinges attached to the dash. The magneto and the carburetor are reached by lifting the hood and the clutch and gearset case are accessible by lifting the floorboards. The clutch can be taken out without removing the motor or the gearset, and the gearset may be dropped without disturbing the clutch. By loosening a winged nut and a clamp the mud pan can be drawn forward and the lower half of the crankcase exposed, and the lower section of the case can be dropped to reach the motor bearings. Careful provision is made for lubrication, grease cups outside the frame lubricating the clutch and brake countershaft, and the springs are fitted with self-lubricating bolts. The gasoline tank capacity is 20 gallons.

The chassis is fitted with a driver's seat and front mudguards, as well as the usual tools and tire repair kit. The company is prepared, however, to supply bodies of standard types.

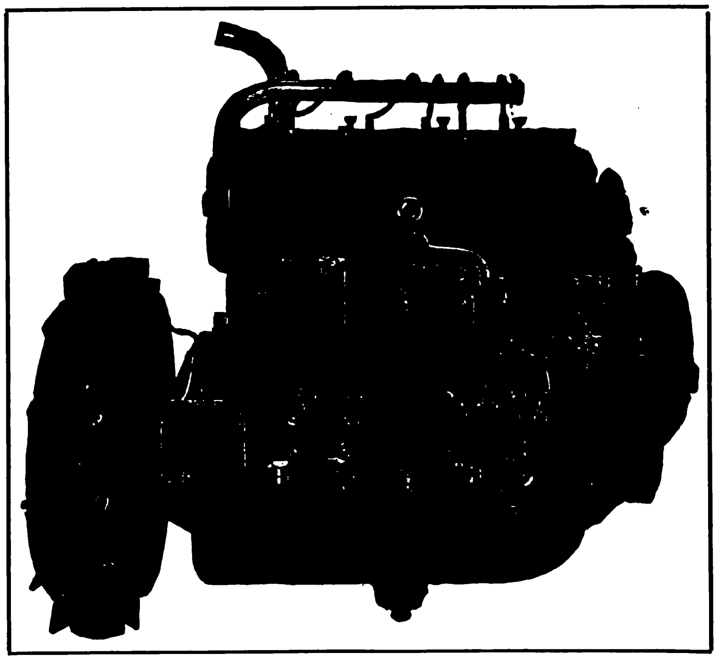
FORTY PER CENT. STOCK DIVIDEND.

Packard Motor Car Company's Capital Increased from $10,000,000 to $16,000,000.

The owners of the common stock of the Packard Motor Car Company who had for four years permitted the earnings of their stock to be applied to the development of the business, received a stock dividend of 40 per cent. at the annual meeting of the company Oct. 16. The stockholders voted to authorize the increase of capital from $10,000,000 to $16,000,000, by issuing $3,000,000 each common and preferred stock, and besides the stock dividend of $2,000,000 in common stock, the remaining $1,000,000 common stock and $3,000,000 preferred stock will be retained in the treasury. The stockholders waived right to the common stock and this will be issued as funds are needed by the company, and the $3,000,000 preferred stock, to which right was also waived, will be retained as a reserve to take up the issue of $3,000,000 five per cent. gold notes that will mature Dec. 1, 1916, or may be devoted to other purposes in the event of need. The statement is made that when an issue of capital stock is authorized considerable time must elapse before the requirements of the Michigan law can be conformed with, and the officials of the company believed it best to have some of the company's stock where it could be available when it would be needed.

The directors elected were: Henry B. Joy, Richard P. Joy, Fred M. Alger, Russell A. Alger, Philip H. McMillan, Truman H. Newberry, all of Detroit, and J. W. Packard of Warren, O. The directors elected the following officers: President, Henry B. Joy; vice presidents, Russell A. Alger and S. D. Waldon; secretary and treasurer, Philip H. McMillan; general manager, Alvan Macauley.

The annual report of the company of Aug. 31 shows that during 1912-1913, 3994 vehicles were built. The receipts during the fiscal year were $18,606,752.34, and including a cash balance of $1,030,519.95, the total was $19,637,266.29. The disbursements were $18,262,-315.17, leaving a cash balance of $1,374,951.12. The assets, including a plant valued at $5,260,950.28, and branch investments of $1,481,893.61, amounted to $17,-339,848.10. The liabilities, including $5,000,000 common and $5,000,000 preferred stock and $3,000,000 outstanding gold notes, and a surplus of $3,006,256.22, showed the same total. The net profit for the year was $2,157,472.40. The company during the fiscal year

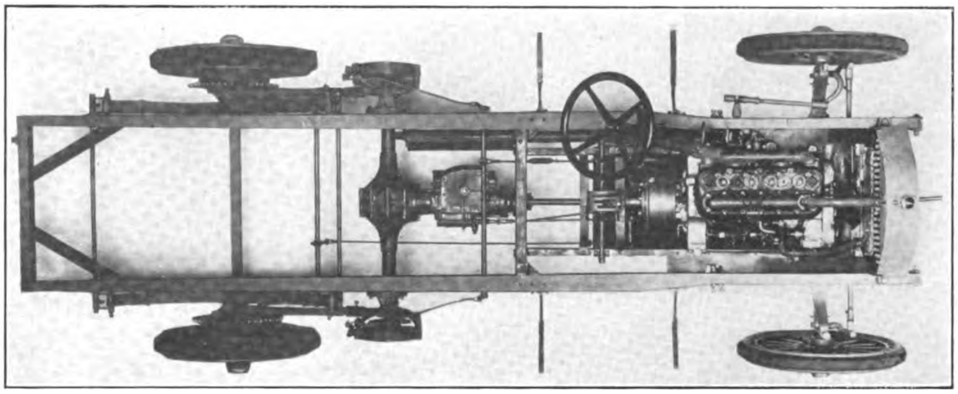


The Right Side of the Motor Used in the Lippard-Stewart 3000-Pound Wagon Chassis.

produced the largest number of vehicles in its history and the prospects were regarded as being particularly promising, both for pleasure vehicles and for trucks.

REPUBLIC 1500 TO 2000-POUND DELIVERY WAGON.

THE Republic motor wagon, of 1500-2000 pounds capacity, built by the Alma Motor Truck Company, Alma, Mich., is specialized by this firm, but one type of chassis being produced. The machine is designed from the standard productions of manufacturers who specialize the building of motor vehicle parts, and it is maintained that the designs, material and workmanship have been proven to be in every way satisfactory and enduring. It is further claimed by the maker that all of the units used in the construction of these machines are from 50 to 100 per cent. oversized, and that some of them are found in vehicles that have twice the rated capacity of the Republic wagons.



Top View of the Stripped Chassis of the Republic Wagon, Which Has a Rated Capacity of 1500-2000 Pounds.

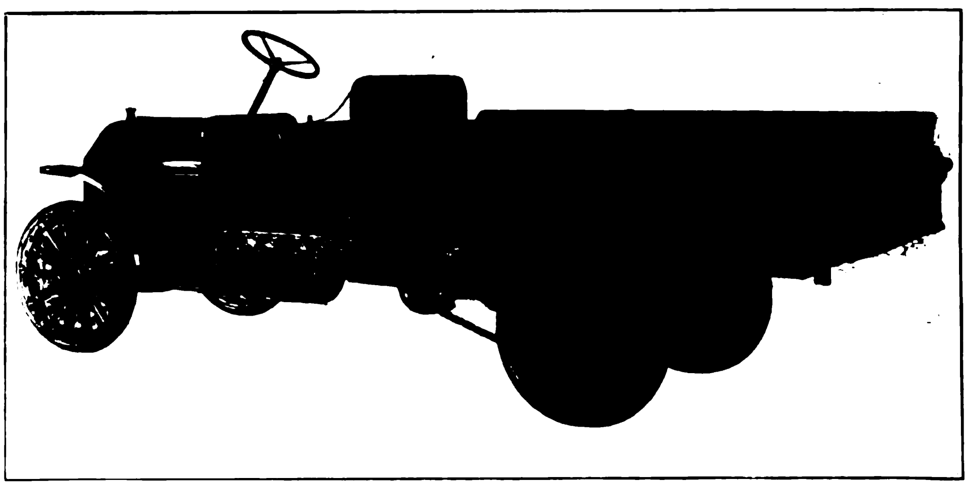
The company purposes to produce approximately 500 machines of this type during the year to come, and it is believed that a vehicle that will be specialized will be better understood and will afford better satisfaction than what might be regarded by some as experimental. In manufacturing, the company claims to have the resources of the best of manufacturers, skilled engineers, splendid facilities and high grade material, and that it is justified in claiming for Republic wagons every requirement that could be sought by a discriminating purchaser.

The motor is a Continental product, being a four-cylinder, water cooled, L head type, with the cylinders cast en bloc, with cylinder bore of 3.75 inches and stroke of 5.25 inches, giving 25 horsepower at conservative rating. The motor is built with the valve mechanism enclosed and it has no exposed working parts. The engine is cooled by a circulation of water through the large cylinder jackets and an ample radiator from a centrifugal pump located at the right side of the motor. A fan that is mounted on an adjustable bracket on the forward end of the engine block is driven by a flat belt from a pulley on the magneto and pump shaft. The motor is lubricated by a combination force feed and splash system, the oil being filtered as it is drawn from the reservoir in the base of the engine crankcase.

The ignition is from an Eisemann high-tension magneto mounted on a bracket at the right side of the motor, and the spark is fixed, there being no hand control lever to regulate the firing of the cylinders. The carburetor is a standard float feed automatic type that is said to give ample mixture at all engine speeds. The motor is suspended in a sub-frame at four points and is protected from the vibratory stresses of road shock and from chassis distortion. The radiator is carried on trunnions that are mounted in supporting cylinders between helical springs, and is protected from strains and distortion that might cause leakage.

The clutch is a Hartford leather-faced cone of large diameter and it is, with the speed changing and emergency brake mechanism, supported on the subframe with the motor, and is free from the effects of chassis stresses. The cone is of large area and it is fitted with a brake to prevent spinning while changing from one speed ratio to another. The driving shaft is carried back from the clutch to the transmission gearset, which is incorporated with the jackshaft, in a straight line, and it is fitted with two universal joints. Great care has been taken to secure perfect alignment of the shaft, which minimizes power consumption and insures against side pressure.

The transmission gearset is a Covert model GI sliding gear construction, that affords three forward



The Republic 1500 to 2000-Pound Wagon Chassis Fitted with a Standard Type of Express Body, with Flareboards.

speeds and reverse, and it is assembled with a jackshaft built by the Russell Motor Axle Company. The jackshaft is suspended from the chassis frame by bell shaped brackets, and these also carry the forward ends of the radius rods, so there is no strain upon the jackshaft or its housing. Hyatt roller bearings are used throughout the jackshaft and the gearset. The drive from the jackshaft to the rear wheel is by detachable link chains.

The chassis frame is of large steel channel section, strongly built and with ample reinforcement. It is carried on semi-elliptic springs forward of 38 inches length and 2.25 inches width, and the rear springs are 46 inches length and 2.25 inches width, the springs being of a high quality of carbon spring steel. The rear springs are mounted with the hangers and shackles outside of the frame, this making for a low loading height and a steady body. The axles are steel drop forgings of ample size and as the chassis is constructed 30 per cent. of the load is carried on the forward wheels and 70 per cent. on the rear axle. The front wheel spindles are 1.75 inches diameter and the rear axle spindles two inches diameter. The wheels are mounted on Bower roller bearings. The wheels are an artillery type, with 34 by 3.5-inch tires forward and four-inch tires rear. Because of the full universal type construction of the radius rods there are no strains at any time upon the rear axle or driving mechanism. The service brake of the contracting band construction operates on 10-inch drums on the ends of the jackshaft, and the emergency brake of the internal expanding type operates within 14-inch drums bolted on the rear wheels.

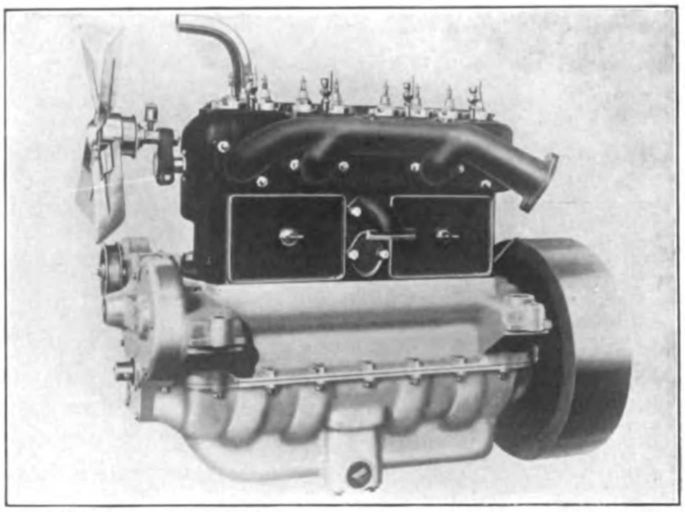
The steering column is at the left side and the control levers are at the right of the driver. The steering wheel is free of levers, the ignition being fixed, and the fuel supply is governed by a foot accelerator on the floorboard, the accelerator being of a construction so graduated that it can be controlled by side instead of downward pressure, and uniform speeds can be maintained over rough roads and paving. The chassis is regularly furnished with wheelbase of 116 inches, and purchaser may have 124-inch wheelbase if specified.

The standard equipment of the machines is stake or flareboard express bodies, either of which is furnished with the chassis, but special bodies are built to the buyer's specifications. The body shop is prepared to produce whatever may be desired by purchasers at reasonable notice. The sale of the Republic machines is directed by the company from its offices at Detroit, but the export office where the foreign business is transacted, is at 17 Battery place, New York City. The company has developed business in South America and the West Indian islands, as well as in other countries, and the prospect for this is said to be very gratifying.

TRUCK HAULED 18-TON LOCOMOTIVE.

The Beaver Engineering & Construction Company is engaged on a big contract at West Brighton, Staten Island, and recently three 18-ton locomotives were delivered at Tompkinsville, S. I., by the Baltimore & Ohio railroad for use on this work. To convey the engines to West Brighton they were loaded on platform trucks that weigh six tons each, and these trucks and the locomotives were hauled over the road by a La France hydraulic truck. The distance was not great, but there were a number of grades which had to be ascended.

From the B. & O. freight yard in Bay street a four per cent. grade was traversed, and in the Richmond turnpike for two blocks a grade from eight to nine per cent. was met with that was two long blocks in length. As the truck started up this hill a priming cock on the engine opened, and in trying to close it the cock was broken off. The truck was worked with three cylinders and drew the load to the top of the hill. Here a repair was made. Beyond this point a grade of 10.5 per cent. was climbed for 800 feet, and after a level stretch of about .75 mile a hill .75 mile length and with a 12 per cent. grade was ascended without difficulty. The destination was about a quarter mile beyond this hill.



Left or Valve Side of the Motor of the Republic 1500 to 2000-Pound Wagon.

The truck hauled the three locomotives on all the grades and seemingly had not at any time reached the limitation of its haulage capacity. The La France truck has been used for a great deal of very heavy transportation work in New York and vicinity and because of its proven capacity it was secured for the moving of the engines.

The Pope & Talbot Company, contractor, of San Francisco, Cal., recently hauled with a Knox-Martin tractor a piece of timber 103 feet length and 28 inches square, weighing between 13 and 14 tons and containing more than 6000 board feet of wood, through the streets of San Francisco and delivered it at the site of the new city hall, where it will be used as a part of a derrick for handling structural steel and other heavy material. The timber was drawn through the streets and turns made without obstructing the heavy traffic.

ADVERTISING RATES.
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

FENDER EQUIPPED TRUCKS.

In several cities recently ordinances have been passed requiring owners of service wagons to equip them with fenders, and in every instance the ordinance has not indicated what form of fender would be satisfactory. The burden has been placed on the owner by providing that the fender must be satisfactory to the authority entrusted with the enforcement of the measure. Neither is there a very clear idea of how a fender can be installed that will meet the assumed purpose of the ordinances.

There is the matter of road clearance, which is an entirely different proposition than is met with in a street railroad car, and the 30-degree angle swing of the steering wheels necessitates a construction that will be considerably wider than the hub caps. The fender must have sufficient inclination to lift obstructions, and this implies considerable length when the device must be suspended from the ends of the spring horns, or an extension of the frame, sufficiently forward to permit full swing of the wheels. The fender ought to be collapsible to economize garage space, and to allow use of the machines in limited spaces, but as the fenders are assumed to be open while the vehicles are in use there is no question that in whatever form they are used they will greatly hamper the drivers in traffic.

There may be a worthy purpose in the minds of those who enact such ordinances, but much more satisfactory results could be accomplished by suppressing the speed maniacs who drive passenger cars, even to the extent of jail sentences.

THE PROBLEM OF TRANSPORTATION.

No subject is of greater importance to the business man of today than transportation economy, and there is seemingly a very logical and necessary reason why it should receive the attention of local organizations composed of men who are engaged in industry or commerce. Each community presents a different phase and the conditions are best known to those who have to meet them. Where traffic regulations are considered advisable the boards of trade, chambers of commerce and associations of business men should participate in at least the preliminary investigations, and restrictions should not be adopted until after careful inquiry has determined that the best has been devised. These organizations can, by concerted endeavor, bring about changes that will be decidedly beneficial, and can minimize congestion at docks and railroad terminals, as well as influence improvements by new methods and changed facilities for handling goods. Owners of delivery equipment, heads of shipping departments, haulage contractors, officials of labor organizations, police officials, superintendents of transportation for railroads and steamship lines, freight agents, pier superintendents, traffic managers and others can be consulted, and where these interests are harmonized there is little doubt that a great saving could be made.

LIMITING TRUCK WEIGHT.

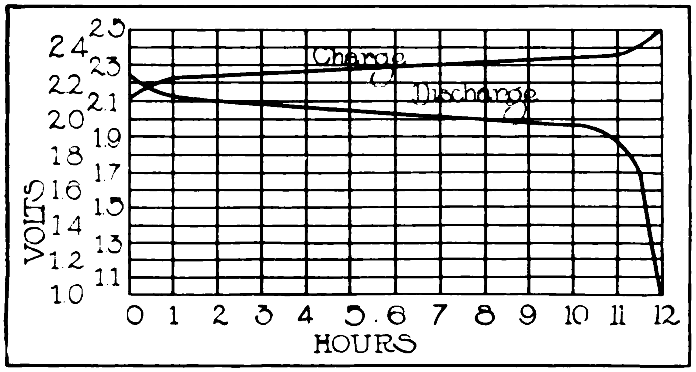
Limiting the weight of trucks has been agitated by elements in differing states and municipalities. Three reasons are urged, the first being the strength of bridges, the second the strength of paving, and the third the congestion in narrow streets. There is evident fear from some, generally the people of the small towns who will benefit from the increase of highway traffic, that they will be required to reinforce bridges that are inadequate for the weights they might be required to support under some circumstances. Such bridges are very few and yet are the basis of the arguments of the legislators. The possible deterioration of paving under the weight of traffic has caused another alarm for some of the city statesmen, and the remedy is believed to be the limitation of the weights of the vehicles and the continuance of the use of the obsolete pavements. The narrow streets, especially those that will not allow more than two wagons or trucks abreast, are regarded as an argument for minimizing the size of bodies. How really logical these arguments are can be judged. Equally satisfactory reasons have been given by those who have opposed the progress of civilization, but the demands of the people have always prevailed. The public today requires economy and efficiency, which can be obtained in greatest measure with large motor vehicles.

ELECTRIC VEHICLE PRACTISE.

The Electrolyte of the Lead-Acid Cell and Variation of Effect with Changes of Temperature and Density---Results Caused by Normal Charging and Discharging and the Ultimate Deterioration of the Plates.

William W. Scott.

STORAGE battery cells, so-called, when utilized for vehicle propulsion, are subjected to the stresses of road shock, and to more or less wear in



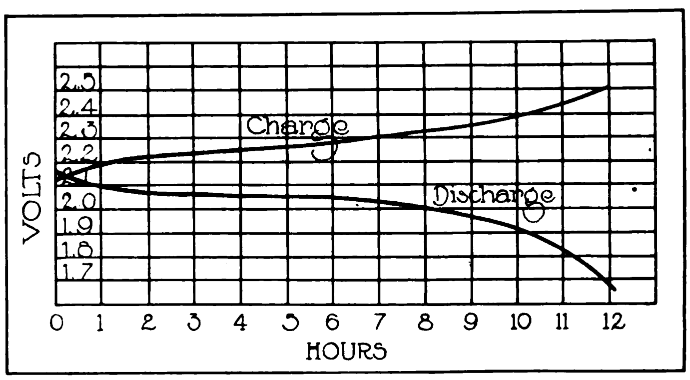
Curves Showing the Charge and Discharge of a Well Constructed Lead-Acid Battery Cell.

handling, and of necessity the construction must be such that they will endure. Vehicle battery cells are practically formed of hard rubber, with walls varying from .0625 to .125 inch thickness, and to minimize weight the volume of electrolyte is generally the smallest volume that can be depended upon to yield the necessary amperage, the quantity depending upon the area of plate surface exposed to the solution. Because the cells are subjected to movement and there will be more or less agitation of the fluid they contain, such cells are sealed, the cover fitting tightly about the element and the joints being filled by a sealing compound, which is applied in a plastic state, being heated and solidifying when cool. The necessity of equalizing the electrolyte and observing the condition with reference to covering the elements in the cells is provided for by one or more holes in the covers, which are closed by tight fitting plugs, in which are vents which allow the escape of gas and yet prevent the electrolyte being thrown from the cells by the motion of the vehicle and in handling the cells.

The size of the cells depends upon the amperage capacity desired, which is governed by the plate area, and plate area is increased by adding plates, for this is regarded as better practise than by increasing the size of the plates. The larger the plate the greater the proportionate weight and the greater the probability of "buckling" or distortion. In practise the small plate in increased numbers is found to afford the better service, and varying the number of plates increases the dimensions of the cell in every way save in length or depth. Obviously the thin plate minimizes weight of element, and there must be a sufficient volume of electrolyte to produce the necessary activity.

There is a limit to the size of the cells because of the space in which they are carried, and there must be a specific number to obtain the necessary voltage. As each cell is roughly rated at two volts, and a maximum capacity is desirable, the battery is determined by the motor voltage. Taking a motor rated at 80 volts, for instance, the capacity of the battery is the difference between the maximum voltage and the voltage of the motor. That is, an 80-volt motor will require that voltage to operate it, and with such a motor the usual battery is 44 cells. If these were of two volts capacity each this would give 88 volts, but as these may be charged to 2.5 volts each this gives a battery capacity of 110 volts, and an operating voltage of 30. The main line voltage, from which the charging current is drawn, may be 110, 115 or 120, and assuming it is 115, the highest voltage that could be given with this would be 2.61 volts. But the line and battery resistance must be considered, and this will cause a reduction of voltage, so that 2.55 would probably be the maximum, save under unusual conditions. Considering the maximum discharge capacity indicated by the fall in voltage from 2.55 to 1.80 volts, as shown by each cell, at which the battery voltage would be 79.2, the total working range of the battery would be 33 volts.

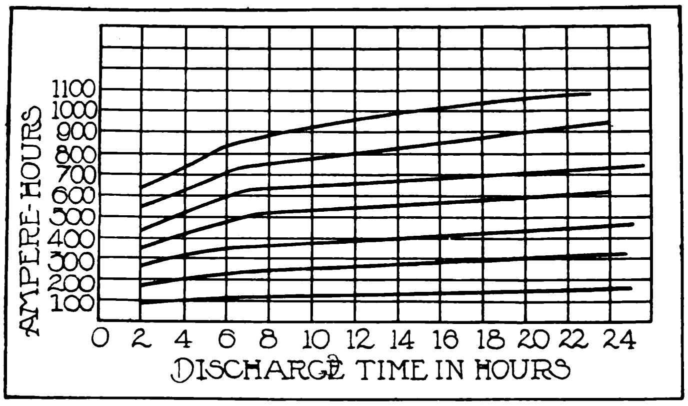
By this is meant that the maximum pressure of the voltage, with the cells connected in series, would be 33 volts. The amperage, however, with the cells connected in series, is that of any one cell, and taking a 225 ampere-hour cell and remembering that the amperage is usually expressed at the eight-hour discharge rate, the cell would be rated at discharging 28 amperes for eight hours, but a far greater amperage could be



Curves of the Charge and Discharge of a Lead-Acid Battery Cell of Standard Type.

discharged for a shorter period. This quality has been previously explained. To obtain this greater amperage or flow of current the cells must be coupled in mul-

tiple. It should be borne in mind that the voltage of a battery is expressed in the combined voltage of the cells in series, but the amperage is expressed in the



The Relation Between the Capacity and Discharge Rate of a Lead-Acid Cell.

capacity of a single cell at the normal discharge rate, which is eight hours.

The owner of a vehicle or even a battery expert has no real interest in the elements that enter into cell design, because there is no reason for concern. The engineers have no doubt produced what has been carefully worked out by theory and developed by experiment until a cell as placed in the market has known quality and capacity, and ought to be regarded as factory perfect when it is delivered. As a standard cell a definite work can be expected from it. Usually the cells are shipped ready for use aside from a freshening charge if several days have elapsed since it was sent from the factory.

But the really important factor in the operation of the battery is the electrolyte. This must be maintained at a standard of quality and the owner, user or the battery man must not only know this, but understand what attention is necessary to obtain efficiency.

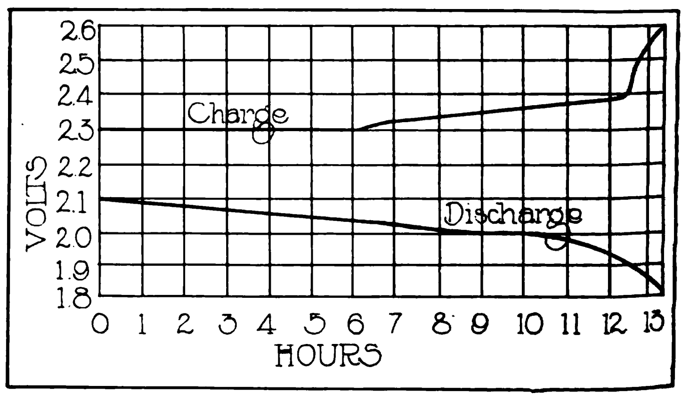
The electrolyte of a lead battery cell is an admixture of sulphuric acid and water perfectly free from all substances and organisms, and this purity cannot be insured in any other manner than distillation. For that reason distilled water is an absolute necessity, and should always be used save in certain emergencies that will be stated. This reservation, however, should not be regarded as a license to use undistilled water. A battery cell is too valuable to risk damage by violation of this rule.

The specific gravity of the electrolyte of cells of batteries used for vehicles is considerably higher than of those used for other purposes. The highest gravity that is found in vehicle battery practise is 1300, which corresponds to 39 per cent. sulphuric acid by weight, and the usual standard of gravity that is advised for battery operation is 1285, or from about 36.5 to 37.5 per cent. acid by weight. Batteries used for other purposes are operated with electrolyte of much less density. It may be stated that the average density is, for such cells, about 1200. That the density of the electrolyte is influenced materially by temperature should be understood, for this factor has decided bearing on the readings and, consequently, on the results.

Primarily an electrolyte is a dilute sulphuric acid, and the density may be shown by the percentage of acid by weight, but this is usually expressed in the specific gravity reading. There are equivalents in percentage for the expressions in specific gravity, which are available for engineers and those who might have need of them, but there is really use for only the latter. These, however, are subject to correction because of temperature variation. But a very simple rule will make it possible for a battery man or even a novice to reach a very accurate determination when using the hydrometer. Because of this variation in density there is necessarily a variable potential, and for that reason charging is recommended at a temperature of 70 degrees Fahrenheit when gravity readings are to be taken, and results are more accurate when this standard is recognized. Engineering records are usually taken at 60 degrees Fahrenheit, but this standard is sometimes departed from. The reason for this is that numerous charts have been worked out and at 60 degrees they can be utilized without correction.

The electrolyte ordinarily used when a vehicle battery is shipped from a factory has a specific gravity of close to or about 1300, when fully charged, and the instruction of the maker is to maintain it at 1285 when fully charged and not to discharge it below 1.8 volts a cell, which is equivalent to a gravity of about 1170. At a specific gravity of 1285 the percentage of acid is 37.5, and at 1170 it is 23.7 or thereabouts, so that there is material change in specific gravity of the electrolyte during charging and discharging. In charging the density increases, and in discharging it decreases.

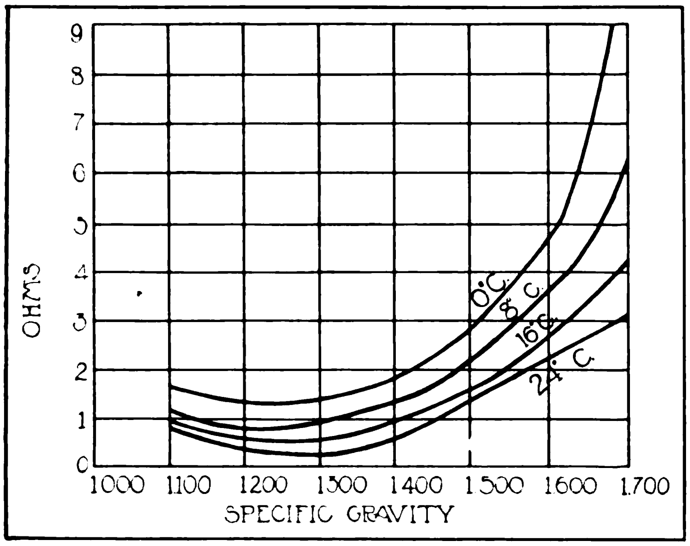
The reason for this change in density has been stated in that chapter that dealt with the general phenomena of secondary cells, but an explanation will not be out of place at this juncture. The sulphion of the acid, that is, the radical that is in solution in the electrolyte, is by the charging released from the lead sulphate formed on the plates when the cell was discharged, and the active material is restored practically to its original form of lead peroxide for the positive plate, and to sponge lead for the negative plate. If the



The Discharge Curve of a Lead-Acid Cell.

charging is at a slow rate and sufficiently prolonged the radical is practically eliminated from the pores of the two plates. As this radical is dissolved it is taken

up by the water and the density is increased. As the cell is discharged the acid radical unites with the lead peroxide and the sponge lead and forms lead sulphate,



Curves Showing the Specific Resistance in Ohms and the Specific Gravity of Electrolyte at Different Densities and Temperatures.

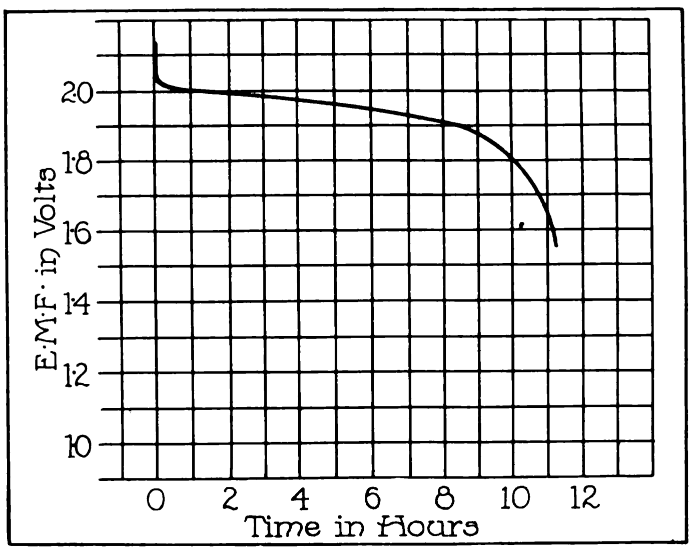
and as this formation takes place the density of the electrolyte is decreased. As has been stated, this formation could continue until the electrodes were reduced to lead and the radical practically reduced from the electrolyte, but to reach this condition, which might be expressed as equilibrium, the lead sulphate would be so heavily deposited that it is doubtful that it could be more than partially removed, and the cell would be materially damaged. This excessive degree of sulphation is to be avoided, and the formation of sulphate prevented below a point where it can be eliminated by charging, by stopping discharge when a voltage of 1.8 a cell is indicated, or when a specific gravity of 1170 is shown.

The electrolyte must be of sulphuric acid made from sulphur. Sulphur that is sold to sulphuric acid manufacturers is refined and rated as chemically pure, and it contains a very small proportion of impurities, which are eliminated by the production of the acid, so that dependence can be placed on this product. Sulphuric acid can be obtained that has a specific gravity of 1845, which is a degree of concentration regarded as a standard by battery engineers. The acid should be diluted with a distilled water that is known to be pure. That is, which has not been exposed to contamination by organisms or mineral substances.

In battery manufactories special equipment is installed for mixing electrolyte, as great care is taken to keep it pure. Where electrolyte is made in such quantities as would be needed in a garage, even of considerable size, the requirements are exceedingly simple and inexpensive, but facilities may be used that can include elaborate apparatus. The statement has been made that the sulphuric acid should be made from sulphur, for acid made from pyrites will often contain particles of iron, and other substances that will seriously affect the electrolyte.

Sulphuric acid manufacturers often prepare a dilute solution that is intended specially for use in storage battery cells, and the claim is made that this has every desirable quality and is ready when required, while it is exactly proportioned. Where a cell is to be entirely filled there is no question of the advantage, but the cost is generally considerably in excess of electrolyte that may be mixed, because there is the weight of the dilute acid as against the weight of the pure acid to be thought of when the cost of transportation is to be paid. Sulphuric acid may be purchased in carboys, and distilled water is procurable in similar containers. These may be kept securely corked and the contents maintained at a known condition of purity.

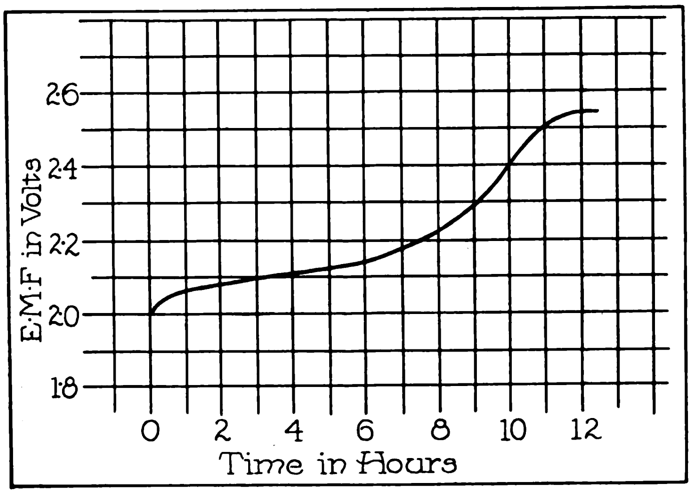
Electrolyte should be mixed in a glass or earthenware jar, crock or vessel, though a lead-lined box may be used if available. The container should be thoroughly cleaned. In this should be placed the distilled water, and then the acid should be added, the acid being poured in slowly and the water and acid mixed by stirring with a glass or rubber rod. A clean wooden stick may be used, but the rod is to be preferred. With the addition of the acid the temperature of the mixture will be considerably increased. The quantity of acid to be mixed with the water will be known by testing the specific gravity, and when the desired degree is reached the electrolyte must be permitted to cool. When cool, however, and the desired temperature is 60 degrees for standard quality, the specific gravity will be found to be higher, and this can be reduced to the reading desired by the addition of distilled water. The electrolyte should be thoroughly mixed before the reading is taken. When the electrolyte when cool is at the desired density it is ready to be added to the cells. This direction, however, applies to electrolyte used for refilling the cells. The specific gravity of the electrolyte for the vehicle battery cell should be aproximately 1285 at 60 degrees



Curve Showing the Fall of the Electromotive Force of a Lead-Acid Cell with the Discharge.

Fahrenheit when the battery is fully charged, and it will then contain about 37.5 per cent. sulphuric acid by weight.

When a battery is received the cells are filled with an electrolyte that has a specific gravity of 1300 or thereabouts. Before a battery is shipped it is given a full charge at a low rate and may be said to have at that time its fullest capacity. The percentage of acid at that reading will be 39. For cells used for power stations the specific gravity at full charge will be from 1190 to 1225, and the percentage of acid will be from 26 to 30.2. This fact is stated to show the greater density of the electrolyte used for the vehicle battery cell. The greater the density of the acid the more active will be the cell, but with the increased density will be a larger degree of sulphation, which accounts for the fact that cells used with stationary batteries will have much longer life than those used in vehicles. The power station cell is drawn upon frequently and yet the charging and discharging is at slower rates as a rule. There is varying resistance of electrolyte, the least being between the specific gravities of 1224 and 1240, and increasing below or above the limitations stated.



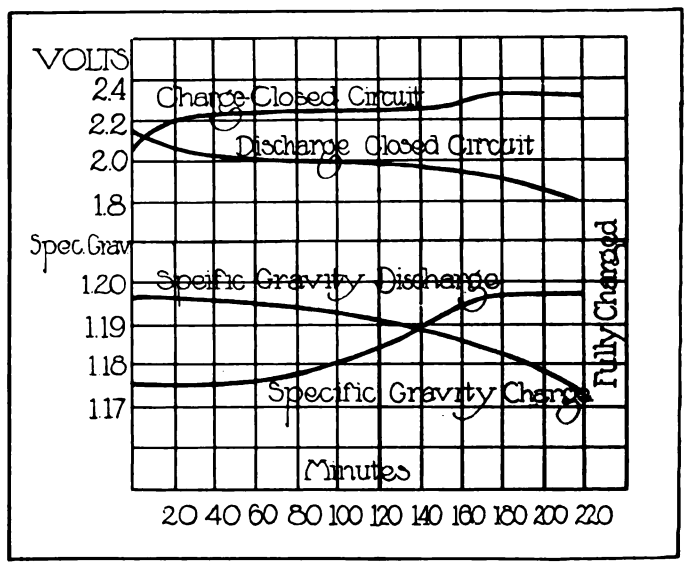
Curve Illustrating the Electromotive Force Required to Charge a Lead-Acid Cell That Gave the Discharge Curve of the Preceding Chart.

Emphasis has been made of the necessity of pure electrolyte. The decomposition of the water of the electrolye in charging causes hydrogen and oxygen to be created and the hydrogen rises to the surface in bubbles and is dissipated. This condition is known as "gassing", and so long as the bubbles arise to the surface and break there is a loss of one of the elements. The recomposition of the water during the period of charging does not restore the hydrogen that has been lost and the electrolyte is constantly concentrating, for the same proportion of acid remains. Then so long as a cell is charged and discharged the density of the electrolyte is increasing, and to maintain it at a standard of efficiency it must be reduced by dilution—by the addition of distilled water. This reduction is known to battery engineers and battery men as equalizing. The process is simply that of adding sufficient water to restore the standard of density.

Because of the addition of water to the cells at such intervals as may be necessary, it is apparent that whatever is carried into the cells with the water must remain there, and impurities which might not be of consequence will, through accumulation, have a very serious influence. Were the water free from all else than organisms these would in time be carbonized or deposited on the plates or separators, and will affect the activity of the cell to a greater or less extent. Matter held in solution in the water might be precipitated and increase the volume of precipitation in the base of the cell. Metallic substances of different natures may be held in solution in the water and sometimes in the acid, and these may include platinum, iron, copper, iron mercury, and all acetates, nitrates and chlorine. The best authorities maintain that there should never be more than one per cent. of iron or any form of nitrogen, ammonia, nitric acid of the total volume of acid in a thoroughly good electrolyte, nor more than .002 per cent. of chlorine.

The platinum, if found at all, will be minute particles held in solution in the acid and introduced with the acid into the electrolyte. High grade sulphuric acid is frequently refined in platinum stills and there is a possibility of particles of the metal being drawn off with the acid. The presence of platinum cannot be well detected unless by test of the acid. which is really a work that only a chemist can determine. The effect of the platinum is to cause discharge of the negative plates, and if an electrolyte is believed to contain platinum it may be tested by placing a quantity in a cell in which are regular plates. With open circuit, should gassing follow for any length of time, the observer can accept the proving of the suspicion.

Iron may be found in acid made from pyrites in sufficient volume to cause damage to the element. It is practical to test the acid to determine whether or not it contains iron, and similar tests may be made for chlorine, nitrates, copper, mercury, arsenic, acetic acid and organic matter. But if care is taken to secure a pure acid and pure water is used, with cleanliness in mixing and using, there is remote probability of impure electrolyte resulting. There. is always a probability of introducing foreign matter into the cells



Curves Illustrating the Variation of Specific Gravity and Voltage of a Lead-Acid Cell During the Charging.

with the water unless special care is taken to keep the cells clean, and those working on cells should be sure that they are free from any accumulations before opening the vents.

The battery cells are usually assembled in crates or trays, these assemblies generally being of such size that they may be conveniently handled, and connectors are often carried from the cells to terminals on the crates that the groups may be coupled, these being so connected with the controller that the groups may be used in combinations. The crates are carried in battery boxes that are intended to afford protection from water, dust and the like. The battery boxes are often ventilated to permit the escape of gas. In rare instances are the cells so carried that there will be no accumulation upon the tops of the cells. Frequently the terminals are given a coating of vaseline to prevent corrosion, and if electrolyte is thrown from the cells in small quantities it will remain on the covers, for should the water evaporate the acid will remain. These conditions are conducive to the retention of dust should it enter the battery box, and because of this possibility the necessity of cleaning the tops of the cells before removing the vent plugs for any purpose is emphasized.

It is evident that when impurities have entered the cells it is impossible to remove them save by removing the elements and renewing the electrolyte, and as this requires time and involves labor, as well as some expense, the advisability of care is desirable from the viewpoint of economy as well as from that of maintenance of capacity and endurance. There are those who may believe that any water that is "soft", such as rain water, may be used, but there is no assurance that such water is free from organisms or particles of iron, and water, unless distilled, may contain carbonates or other elements that may more or less affect the cells.

The effect of the electrolyte at its highest density is to carbonize the vegetable organisms that are in a cell, and while this is a danger of no serious importance, the presence of carbon is undesirable. Water from pipes always contains iron in some form, and iron will affect the plates to a surprising degree. When platinum, which may be found in acid, and iron, which may be found in acid or water, are introduced into a cell the metallic particles will attach themselves to the plates and will cause galvanic action that will continue without interruption, and as this action is a short circuit the result is not only that of discharging the plates, when charged, but will cause deterioration of the sponge lead and the lead peroxide. This condition is known to manufacturers and battery men as local action. There is assurance with cleanliness that the possibility of foreign matter being carried into the cell is reduced to the minimum, and with the use of pure acid and distilled water the electrolyte will be maintained at what may be regarded as the condition that will give reasonable and satisfactory efficiency with any lead battery.

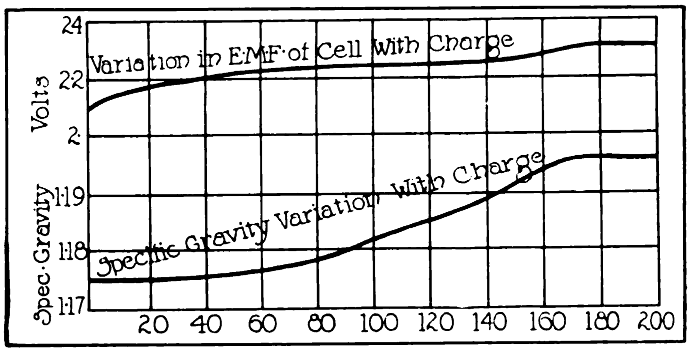
(To Be Continued.)

LORD & TAYLOR BUY ELECTRICS.

Leading New York Department Store Orders 36 Machines for Direct Delivery.

Lord & Taylor, a firm conducting a New York City department store that is known throughout America as one of the most thoroughly dependable of concerns, and has a reputation for distributing the highest quality goods, does a very large business in the metropolis and vicinity. After very careful investigation of delivery equipment, with a view of economizing in its transportation and affording its customers the service that is believed to be essential, the firm has decided to practically transform its vehicles from animal drawn to motor driven, and to this end has ordered 36 1000-pound wagons from the General Vehicle Company, these to be delivered previous to the holidays.

The company purposes to have the machines so that it may use them when the demands upon it are the largest, and the requirements most exacting. Provision is being made for the garaging of the vehicles,



Increase of Electromotive Force in a Lead-Acid Cell During the Charging.

and when they shall be delivered practically little will remain to be done.

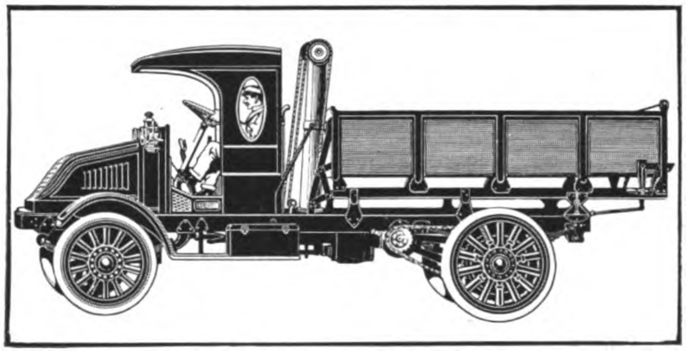
The purchase of these vehicles followed the orders of B. Altman & Co., and McCutchen & Co., for General Vehicle equipment. B. Altman & Co. was the first firm in America, if not in the world, to use electric wagons, its first purchase being made early in 1898, so that it has had more than 15 years' experience with these machines, and at least one of the six small wagons bought at that time is still serviceable. These were 500-pound vehicles, built by the Riker Electric Vehicle Company, and though comparatively light for delivery work they endured remarkably, considering the crudity of their construction and the quality of the materials used.

Lord & Taylor and McCutchen & Co., in the purchases recently made, have secured the latest productions of the General Vehicle Company, the utility of which has been demonstrated by the long experience of other firms.

J. H. Mack has been appointed supervisor of the stations of the Autocar Company in New England with headquarters in Boston.

KELLY TRUCK POWER DUMP EQUIPMENT.

THE Kelly-Springfield Motor Truck Company, Springfield, O., is now fitting the three-ton truck chassis with a power dumping mechanism, which is so



The Power Dumping Body Equipment That Is Now Standard for Kelly Trucks.

constructed that one man can handle machine and unload it with practically no loss of time and with comparatively little effort. The purpose was to simplify the unloading, so that the trucks can be handled by one man on practically all jobs on which they can be worked.

The hoist is built by the Wood Hydraulic Hoist Company of St. Paul, Minn., and it is operated by pumping oil into and from an upright cylinder carried in the centre of the chassis frame behind the driver's seat. The body fittings and the power transmission by which the hoist is driven are the products of the Kelly company's engineers. The hoist itself consists of a long steel cylinder on a base bolted to a frame on the chassis, and in this cylinder is a long trunk piston that is fitted with two piston rings. The piston carries a two-inch diameter rod that extends through the upper or head plate of the cylinder, and this carries a cross arm on which two steel grooved pulleys are mounted. The forward ends of two lengths of steel wire cable are attached to an equalizer, which insures equal strain on each cable, and the rear ends are fastened to the lifting arms attached to the steel body.

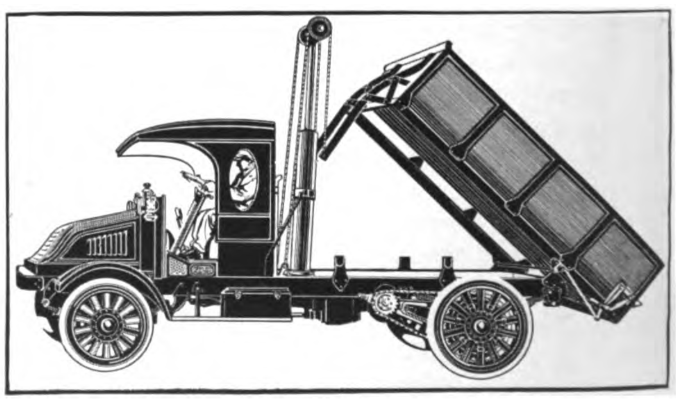
At the base of the cylinder is fitted a gear driven pump, which is operated by chains and sprockets from an extension of the countershaft of the transmission gearset. The speed of the pump is three times that of the engine, this reduction being made so that the engine need not be raced in operating the hoist, and 300 revolutions of the engine will lift the body and a three-ton load and lower it, the operation requiring about one minute. The power of the chassis motor is used, and when the hoist is to be started this is done by the driver disengaging the clutch, as though he were about to shift the speed changing lever. When the countershaft of the gearset has been brought to a standstill a lever at the driver's right is moved and the power connection is made. The lever is located on top of the driver's seat and is out of the way and is convenient when operated.

The engagement of the gear carried on the extension of the gearset countershaft is locked in the same manner as are the sliding bars of the conventional sliding gearset, by spring plungers. These parts are interchangeable with the locks used in the gearset. Because of this positive lock the driver can leave his seat with the hoist in operation until the load has been discharged. After the hoist has been started the driver may leave the machine, walk back and open the tail gate, walk forward to the back of the seat at the right side of the truck, where there is a hand lever that controls the action of the hoist. By pushing this lever from him the hoist will lift the body and by pulling it toward him the hoist will lower the body, and when vertical the hoist is in neutral. When the body is lowered the driver can seat himself at the steering wheel, disengage the clutch, pull the hoist lever to neutral and start the truck. One advantage of the hoist is that no part is in operation save when the load is being discharged. The entire installation is sturdily built and should endure for a long period of time.

Manager Burns of the New Haven, Conn., station of the Standard Oil Company, is authority for the statement that the three-ton White tank truck in the service of that concern is serving as many customers as could be supplied by three and sometimes four two-horse teams and tank wagons. The machine has never been out of service or stalled on the road and it has been driven 5000 miles or more.

A motor omnibus company has been organized to give public passenger service between Cardington and Marion, O., and will operate three machines on 20-minute time.

W. J. McDowell, who has been connected with the Chicago, Ill., office of the General Vehicle Company as salesman, and who had been with that company for three years, has joined the forces of the General Mo-



The New Kelly Truck Power Dumping Body at Its Extreme Elevation.

tors Truck Company at Chicago as salesman for electric vehicles. Mr. McDowell is regarded as having unusual qualifications for selling electric equipment.

Municipal Service Equipment

WHY SHOULD CITIES MOTORIZE?

Knox Automobile Company Official Cites Nine Distinct Advantages Over Horses.

According to Charles F. Barrett, advertising manager of the Knox Automobile Company, Springfield, Mass., maker of Knox fire fighting equipment, there are at least nine distinct advantages of the motor system over the horse method. The list has been compiled from the experience of fire chiefs throughout the country, who give them as follows, in the order of their importance: The saving of time in responding to alarms, larger radius of effective action, ability to get back to quarters more promptly and to get ready for another alarm, ability to carry a more complete equipment and larger complement of men, lower upkeep cost, all the men carried available for fire fighting purposes, saving in fire house investment and upkeep cost, pleasanter and more sanitary quarters for the men, and more time for practise and drill.

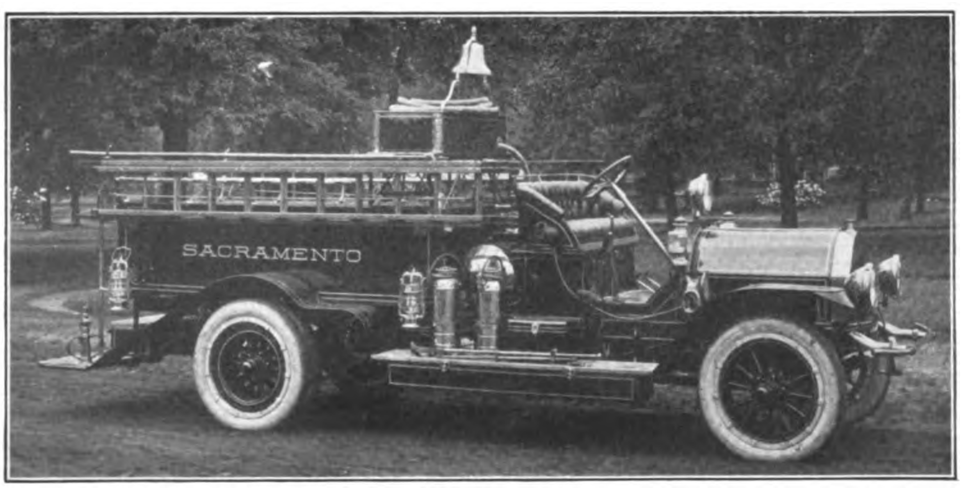
The fire department in Springfield, Mass., which was one of the first cities in the country to adopt motor fire apparatus, now has 30 pieces in service. The officials have kept a very careful account of the cost of both its horse and motor equipment. They find that the latter has saved $8000 this year over last year's budget, although the actual saving was considerably in excess of this amount, as part of it was added to the regular annual appropriation for the purchase of more equipment and the erection of a new fire station.

Respecting the actual saving in fire loss effected by this splendid equipment, the city finds that its fire department answered 829 alarms in 1912, as against 498 in 1907, but in spite of this increase in the number of alarms, the total loss was only $166,000 in 1912, as against $535,000 in 1907. In the latter year the city only had three motor driven machines, so that the greater efficiency due to the addition of more cars is made clearly apparent.

The actual upkeep cost for a two-horse vehicle has been found to average about $524 a year, answering an average of 125 alarms; whereas, the motor vehicle answers an average of 140 alarms at a cost of $181. Five Knox gasoline cars, which bear the brunt of some of the hardest work in the department, average only $34 a year upkeep cost.

Another interesting opinion of the value of motor driven fire apparatus is afforded by the recent report of John H. Dailey, director of the department of public safety in Pittsburg, Penn. He estimates that if his equipment were completely motorized it could maintain a larger force of firemen with the same appropriation than is now possible for the department with horse drawn apparatus. Furthermore, on account of the wider radius of effective action of motor equipment, he believes each company could serve a larger territory, thus making it possible to dispose of some of the stations and concentrate the companies to better advantage.

In the smaller towns and cities the motor fire vehicle has made possible the protection of a very much larger district, so that all taxpayers become interested and are willing to contribute toward the cost of such apparatus. It is pointed out that if such a community purchased, for instance, a combination hose and chemical wagon, it would have a machine capable of giving exceptionally good fire protection for a large district at such a low upkeep cost that the car would pay for itself in a few years on this saving alone. It



Latest Type of Knox Combination Wagon, Recently Installed in Sacramento, Cal.

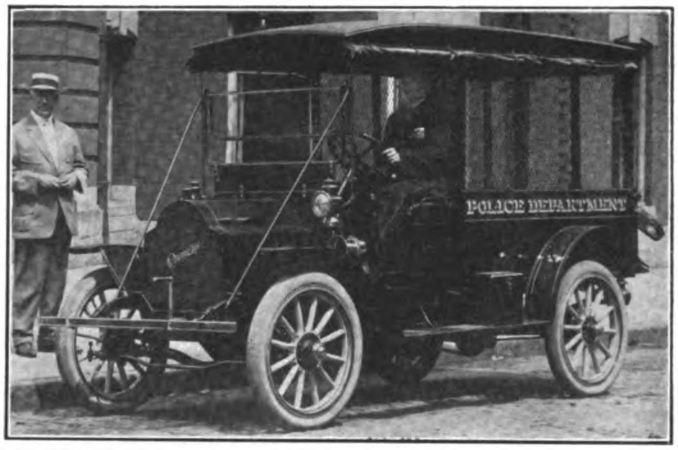
should be remembered, as well, that during the long inactive periods of such a piece of apparatus, it would be costing the community little or nothing, its upkeep cost being approximately in direct proportion to the number of fires.

In view of the advantages to which attention has been directed, it is by no means surprising that cities throughout the country are rapidly installing vehicles of this type. An accompanying illustration shows the latest Knox machine, equipped with electric lighting and all the most modern equipment, recently delivered to the department in Sacramento, Cal. Several machines of this make are doing effective work on the Pacific Coast.

SAVING MONEY FOR THE CITY.

Detroit Police Department Purchases Commerce Car in Interests of Economy.

Those who claim to have given the subject some little study are convinced that one reason why fewer



Commerce 1000-Pound Chassis Fitted with Police Patrol Body for Department in Detroit.

high grade pleasure automobiles are to be found in the second hand market than formerly was the case is due to the fact that many owners of such cars have adopted the plan of purchasing a medium priced machine for everyday use, so to speak. In other words, instead of utilizing the high powered car for running back and forth from the home to the office and about town, this machine is reserved for the more formal occasions and its place in the errand field is taken by a smaller vehicle of less first cost.

The police department in Detroit has a number of patrol wagons which cost the city in the neighborhood of $5000 each. Until recently it was the custom of the precinct officials to send these machines to headquarters twice daily with the reports and any property that might have been taken from prisoners upon arrest. This mileage, when added to that covered in making arrests, brought the total for 1911 to 80,000, and for 1912 to 115,000.

The attention of the police commissioner was called to this matter one day when a policeman stepped from one of these $5000 automobile patrols into his office for a pad of report blanks for a precinct station some distance out. The patrol carried its usual equipment, driver and two officers. The commissioner also took into consideration the fact that when the big car was thus engaged it was absent from duty at the precinct station for which it had been purchased.

The result of this incident was a reorganization of the police patrol system. A 1000-pound Commerce, made by the Commerce Motor Car Company, Detroit, was selected for the errand work. This small car, which is presented in an accompanying illustration, is manned by one policeman, who acts as driver, and it is maintained that it will be but a short time before it will have saved its price, in reduced wear and tear on the larger machines, and in time wasted by salaried patrolmen. The example is one which should prove of interest to other cities, and, indeed, it already has been made the subject of many inquiries to the police commissioner and the Commerce Motor Car Company for particulars.

SPEED OF MOTOR APPARATUS.

Firemen's Herald Expresses Itself Editorially upon an Interesting Subject.

One of the problems which municipal authorities are called upon to face very shortly after the introduction of motor fire apparatus is that of speed. The question is one which has arisen from unexpected quarters just as the fire commission has felt that it had acquired a vehicle which would reduce fire loss largely because of its speed. The Fireman's Herald, a publication devoted to fire department interests, has been requested by a correspondent to voice its sentiments upon this matter, which it does as follows:

> Our opinion is that the highest measure of safety can only be attained through the careful selection and adequate training of fire chauffeurs. The competent man will know when 10 miles an hour is dangerous and 30 an hour reasonably safe. The incompetent man will endanger the lives of everybody on the fire car and on the street, no matter how slowly the car is being driven.
>
> To say arbitrarily that motor apparatus may under no circumstances move at a higher speed than one much less than its maximum, is to rob the automobile of one of its greatest usefulnesses in the fire service. To have an incompetent man at the wheel is a crime.

EXIT THE LAST HORSE.

Fire Department in Youngstown, O., Is Now Completely Motorized.

Youngstown, O., enjoys a unique distinction in the Middle West. It now has an absolutely horseless fire department. The last team in the service was sold Aug. 30, to a liveryman. Harvey Leedy, the driver, made a last exhibition run on the day of sale, but for some time the horses had appeared out of place, being the only pair to answer alarms in any part of the city.

There was a time when the lone Webb pumping engine was the novelty of the department, but its per-

formance was so successful that it was soon called upon to share this novelty with others. Youngstown has 11 stations. One after another was motorized, until the horses at No. 4 in Falls avenue were left to demonstrate the effectiveness of the newer type of apparatus. Station No. 4 now has a Knox machine.

NEWS FROM VARIOUS CITIES.

Decides upon American-La France—After some little discussion of the various propositions laid before it, the fire department in Maynard, Mass., has decided to install an American-La France combination chemical engine and hose wagon, made by the American-La France Fire Engine Company, Elmira, N. Y.

Purchase Seagrave Combinations—The fire department in Freeport, Ill., has placed in service the first of three Seagrave motor combination hose and chemical wagons, made by the Seagrave Company, Columbus, O. The fire officials in Paco, Wash., have contracted for an 80 horsepower combination wagon of the same make.

Want Reduced Insurance Rates—The town council of Kearny, N. J., has decided to defer action concerning the purchase of an automobile fire engine, until it can be learned definitely what reduction will be made in existing fire insurance rates. At present the council favors the proposition, and the chief is strongly urging immediate action.

Garford Trucks in Highway Construction—After conducting a series of tests during the past year to determine the relative economy and efficiency of motor trucks and horse drawn vehicles, the Eastern Asphalt Company, New York City, has added to its equipment, two six-ton Garford trucks, made by the Garford Company, Elyria, O. These machines will be utilized in transporting asphalt from the mixing plant to the various paving jobs about the city, for which the concern has the contracts. Special dumping bodies, designed for quick unloading, have been fitted.

In the Market—The following cities are contemplating the purchase of motor driven fire apparatus: Rochester, N. Y.; Fond du Lac, Wis.; Montgomery, Ala.; Provo, Utah; Albuquerque, N. M.; Watsonville, Cal.; El Paso, Tex.; Sioux City, Ia.; Philadelphia, Penn.; Somerville, Mass.; Milwaukee, Wis.; Joliet, Ill.; Escondido, Cal.; Cooper, Tex.; North Attleboro, Mass.; Clinton, Ia.; Saginaw, Mich.; Lake City, Fla.; Taunton, Mass.; Merrill, Wis.; Hamilton, O.; Grass Valley, Cal.; South St. Paul, Minn.; Cedar Rapids, Ia.; Dartmouth, Mass.; Fort Madison, Ia.; Suffield, Conn.; Adrian, Mich.; Sandusky, O.; Baton Rouge, La.; Northumberland, Penn.; Erie, Penn.

Water Department Motorized—It is stated that the water department in Hartford, Conn., is now completely motorized. The last car to be added was a 1.5-ton Pope-Hartford, made by the Pope Manufacturing Company of that city, and this is used for hauling the smaller sizes of pipe, tools, corded wood for the metal pot fires, and other material of that description.

Presents Ambulance to Montgomery—Realizing the splendid benefits arising from the possession of an automobile ambulance, James C. Haywood, Montgomery, Ala., has installed a machine of this character and announces that its use is free to the general public.

Buicks for Water Department—The Dayton-Buick Company, a new concern, organized recently to handle Buick cars, made by the Buick Motor Company, Flint, Mich., in Dayton, O., has secured a contract to supply the water works department of the latter city with two Buick machines of the roadster type.

Selects Federal Fire Wagons—For some time the city government of Lynn, Mass., has had two Federal trucks, made by the Federal Motor Truck Company, Detroit, in service, one with the water department and the other with the highway department. When the question of securing additional fire apparatus came up recently, the decision was soon reached to purchase Federals. Three pieces have been ordered.

Buys Additional Peerless Apparatus—Some six months ago the fire department in Cleveland, O., purchased six pieces of motor apparatus produced by the Peerless Motor Car Company of that city. The vehicles, which were of a new type then just being introduced by the Peerless concern, gave such satisfaction that orders have now been placed for three combination wagons and a hook and ladder service car.

Cars for Kansas City Police—The police department in Kansas City believes thoroughly in the practicability of the motor car. Several burglaries have been committed in the outskirts of the city, and motorcycle policemen have been assigned to these districts. In addition, three five-passenger touring cars have been purchased. During the day these machines will be utilized in suppressing speeding on the boulevards, transporting prisoners, etc. At night they will be held subject to call in an effort to apprehend house breakers.

Motor Weighing Machine—The Gregoire company of France has recently supplied to the police authorities in Paris a nine horsepower friction driven car, intended for the prevention of frauds in the sale of coal and other goods in bulk. The platform of the car is really a scales, which is brought into operation by means of four collapsible legs. When the weight inspectors, in their travels, decide to stop the vehicle and test the weight of the sacks, the four legs are fixed on the ground, which action slightly raises the weighing machine platform from the chassis.

PREPARING THE ANTI-FREEZING SOLUTION.

WITH the approach of cold weather preparations should be made to guard against the freezing of the water in the cooling system of the car, especially if the machine is subject to long waits in the open. Some do not advocate the use of anti-freezing solutions, relying upon their drivers to run the motor occasionally when waiting for a load and when it is very cold. There are, however, a large number of operators who prefer to utilize such solutions and the accompanying tables showing the percentages of water and ingredients to employ will be useful in preparing the car for cold weather service.

There are several ingredients used and these are mixed in certain proportions, according to existing conditions and locality. The most common are alcohol, calcium chloride and glycerine, although there are several chemical solutions which can be purchased already prepared.

ANTI-FREEZING SOLUTIONS AND THEIR FREEZING POINTS.

Mixture		Degrees F.
Calcium Chloride.		
1 pound salt—1 gallon water	Freezing point	27
2 pounds salt—1 gallon water	Freezing point	18
3 pounds salt—1 gallon water	Freezing point	1.5
4 pounds salt—1 gallon water	Freezing point	—17
5 pounds salt—1 gallon water	Freezing point	—39
Glycerine.		
Water 95%—Glycerine 5%	Freezing point	30
Water 90%—Glycerine 10%	Freezing point	28
Water 85%—Glycerine 15%	Freezing point	25
Water 80%—Glycerine 20%	Freezing point	23
Water 75%—Glycerine 25%	Freezing point	19
Water 70%—Glycerine 30%	Freezing point	15
Water 65%—Glycerine 35%	Freezing point	12
Water 60%—Glycerine 40%	Freezing point	5
Water 50%—Glycerine 50%	Freezing point	— 2
Water 45%—Glycerine 55%	Freezing point	—10
Alcohol and Water.		
Water 95%—Alcohol 5%	Freezing point	25
Water 90%—Alcohol 10%	Freezing point	18
Water 85%—Alcohol 15%	Freezing point	11
Water 80%—Alcohol 20%	Freezing point	5
Water 75%—Alcohol 25%	Freezing point	— 2
Water 70%—Alcohol 30%	Freezing point	— 9
Water 65%—Alcohol 35%	Freezing point	—15
Water 60%—Alcohol 40%	Freezing point	—23
Water, Alcohol and Glycerine.		
Water 95%—Alcohol-Glycerine 5%	Freezing point	28
Water 90%—Alcohol-Glycerine 10%	Freezing point	25
Water 85%—Alcohol-Glycerine 15%	Freezing point	20
Water 80%—Alcohol-Glycerine 20%	Freezing point	15
Water 75%—Alcohol-Glycerine 25%	Freezing point	8
Water 70%—Alcohol-Glycerine 30%	Freezing point	— 5
Water 67%—Alcohol-Glycerine 33%	Freezing point	—15
Water 60%—Alcohol-Glycerine 40%	Freezing point	—23

Alcohol Solution.

The alcohol solution is favored because it is easily handled and is a clean mixture. It gives off an odor when heated, however; boils at 172 degrees Fahrenheit, and when used to withstand temperatures below zero heats readily, especially in mild weather. As it evaporates easily under such conditions, it requires attention and the use of a hydrometer to prevent subsequent raising of the freezing point. In radiators having a tendency to leak, this mixture will find these openings on warm days. Denatured alcohol is not expensive and as it may be procured readily, it is generally used.

Calcium chloride, pure, is in the form of prismatic crystals, soluble in one-quarter of its weight in water, and dissolves easily in alcohol.

The commercial form is not expensive and the process of dissolving it may be hastened by using warm water and stirring the solution. In preparation, one should have several strips of blue litmus paper for testing the mixture. If the paper changes to a red color the fluid is slightly acid and should not be used until corrected. This is accomplished by using a slight quantity of milk of lime, adding till color of paper remains unchanged. Crystallized calcium chloride contains about 50 per cent. of water of crystallization and dissolves in about half its weight in cold fluid; consequently, eight pounds of the ingredient dissolved in .5 gallon of water will make one gallon of the saturated solution.

Glycerine and Alcohol.

Glycerine and alcohol are favored by some, but the former is not recommended by some writers because of its alleged deteriorating effects upon the rubber piping. This is not true, however, as the disintegrating effect is upon the compound of the hose, and the action is more noted when the fluid is hot. Glycerine possesses wonderful solvent qualities, dissolving most substances that are soluble in water and some others, for instance, the metallic oxides. It occurs as an oily liquid of specific gravity 1.269, and its boiling point is 554 degrees Fahrenheit. It extracts water readily from the air and when utilized as an anti-freezing solution the connections should be made as tight as possible, for glycerine "creeps", the analogy being the creeping of the electrolyte on the top of a storage battery. This does not dry up, but rather increases, owing to the hydroscopic properties of sulphuric acid. The use of glycerine and alcohol, while more expensive, makes a good mixture in that the former does not boil as readily as other solutions.

In utilizing anti-freezing solutions allowance should be made for the expansion by heat. Where water is employed in the radiator and the container is filled to the top, after a long run the cooler shows a loss. This is due to the expansion and consequent overflow and sometimes to air pockets in the water jackets or piping, which space is replaced by the fluid. When such a loss occurs by evaporation or leakage, the solution should be brought up to its full strength, alcohol by tests with a hydrometer, and calcium chloride by the use of litmus paper. When these are not obtainable a full strength solution should be added.

Previous to the use of anti-freezing solutions the components of the cooling system should be thoroughly cleaned. A mixture of common washing soda and water, is suited for this work. The crystals are added until no more will be dissolved, and after introducing in the radiator, the engine is run for some little time, after which the mixture is removed and the components flushed out with clean water.

FOREIGN TRUCK NOTES OF INTEREST

SCHNEIDER ARMORED WAGON.

New Type of Vehicle of Which Spanish Government Has Purchased 24 for Its Army.

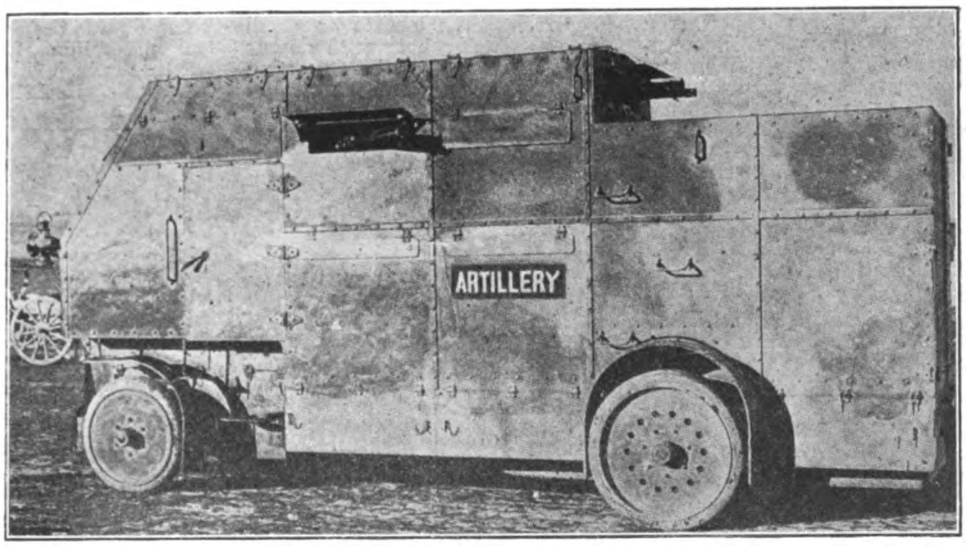
An interesting type of military motor is to be found in the Schneider armored wagon, made by the French firm of that name for the Spanish army. The chassis is that of a standard Schneider truck, fitted with a four-cylinder gasoline motor, with bore of 4.9 inches and stroke of 5.5, rated at 40 horsepower at 1000 revolutions a minute. The cylinders are cooled by water, thermo-syphon system, the radiator being provided with a belt driven fan. A Hele-Shaw clutch drives to the three-speed transmission, final drive being by shaft to a live rear axle. The wheels are of wood, artillery type, shod with rubber and protected by .25-inch sheet metal discs of steel.

The body is divided into three compartments. The front comprises a covered cab for the driver's seat, which is located over the engine. The main portion is in effect a small block house for the accommodation of the men in charge of the quick firing guns. At the rear is the storage space for ammunition.

The front portion of the armoring protects the radiator, the engine and principal mechanical parts. There are two seats in front, that for the driver being at the left, while that at the right is fitted with a folding back and is intended for the commanding officer. Two doors, one at each side, give access to the seats and the interior of the car. There are four movable shutters in front and two at the sides, permitting inspection of the road, etc.

The net available space in the central portion is: Length, six feet six inches; height, six feet four inches; width, five feet seven inches. This is reserved for the riflemen and the men in charge of the quick firing guns, and two longitudinal seats are provided for this purpose. These seats can be folded so as not to interfere with the firing, which, in the event of attack, can take place from both sides of the vehicle through eight shutters, four to each side, so placed as to permit firing in either a standing or kneeling position. An additional shutter at the rear is provided for rear action.

The net available space in the ammunition store is: Length, six feet six inches; height, four feet seven inches; width, five feet seven inches. It is maintained that from 2.5 to three tons of ammunition could be stored in this space if necessary. A folding door, fitted at the back, facilitates quick loading of the compartment. In front, this section is separated from the firing compartment by a vertical wooden partition, with a communicating door. The mechanical parts are protected by armored plate. It is held that this steel plate will give ample security against Lebel rifles at 165 yards.



Schneider Armored Wagon, of Which Spanish Army Now Has 24 in Active Service.

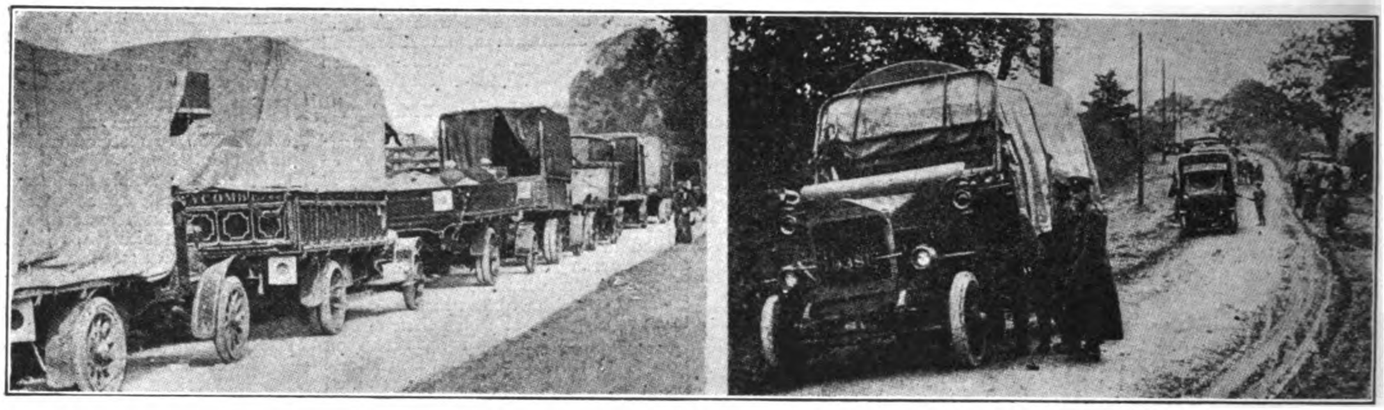
MOTOR AMBULANCE COSTS.

Interesting Figures Made Public by Scottish Hospital Using Argyll Machine.

Dr. A. K. Chalmers, medical officer of health for Glasgow, Scotland, has made public some very interesting figures concerning the cost of a 15 horsepower Argyll ambulance, made by Argylls, Ltd., Alexandria, Scotland, in service with the Ruchill hospital in Glasgow. The figures cover a period of 23 months, or from Dec. 26, 1910, to Nov. 22, 1912, and show an economy over horse drawn vehicles in similar service in the same city of about three pence a mile.

During the 23 months of the observation, the Argyll ambulance covered 19,674 miles, with a total cost of £719 1s 6d, or an average of 8.767 pence a mile, this including the wages, food and uniforms, while the horse drawn vehicle cost approximately one shilling a mile. It is difficult to determine the exact mileage of the horsed wagon, but from a thorough knowledge of the district covered this has been estimated by Dr. Chalmers at approximately 18,328.

These figures, in themselves, are by no means as interesting to the American, as the detailed figures for



Motor Vehicles Transporting Supplies During Recent British Army Manoeuvres: At Left, on the Road; at Right, Awaiting Transfer of the Loads to Horse Vehicles.

the automobile. These are given below, in both English and American money, and their consideration must be governed by the knowledge that the retail prices differ materially in the two countries, as well as the matter of wages. The total cost of the several items with the Argyll ambulance is estimated to have been as follows:

	£	s	d	
Mechanical repairs	70	15	9	$344.49
Repairs to tires	45	14	3	222.46
New tires	148	4	8	721.38
Gasoline	152	14	2	743.16
Oils	10	5	8	50.04
Wages, including food and uniform	291	7	0	1417.86
Totals	719	1	6	$3499.39

MILITARY MANOEUVRES ABROAD.

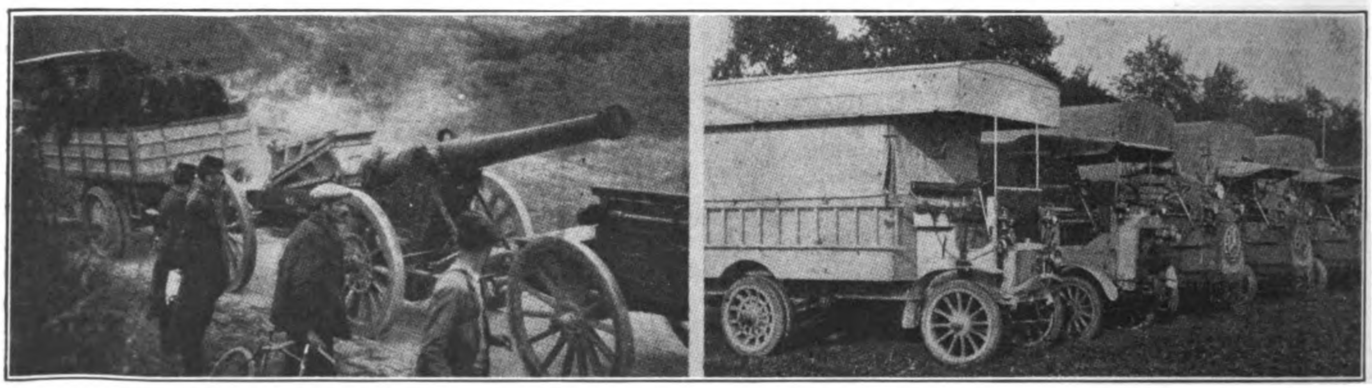
How Motor Vehicles Are Utilized by British and French Armies in Annual Trials.

Since the more general adoption of automobiles and motor trucks in the annual manoeuvres of the state militia in this country, there is increasing interest in the use of such vehicles abroad. It is more or less well known that the armies of Europe are plentifully supplied with automobile equipment, and it is at least suspected that they have carried experimentation of this character much further than is true of the United States government. Somewhat detailed reports concerning the recent manoeuvres of the British and French armies offer opportunity for judging more particularly in respect to this view of the situation.

In Great Britain, the military problem involved the sending of two separate armies against a third, which was supposed to be defending its position in its national capital. Some 58,000 men composed the two advancing armies, and the motor vehicles were utilized largely in bringing provisions, etc., from the railhead to central points, where the contents of the automobiles were transferred to horse wagons for distribution among the different divisions in the field.

It would appear from this statement that the British army officials already had been convinced of the impracticability of utilizing machines in the field, although this supposition can be sustained only by the absence of evidence to the contrary. The trucks followed the main highways, and there does not appear to have been attempt to utilize them in cross country work, their instructions being to follow the army's movement rather than to seek shorter routes to the predetermined rendezvous. In this respect, at least, the task set for the motor vehicles does not appear to have involved serious difficulties, or conditions differing materially from those which prevail at all times in highway haulage.

To each advancing army were assigned 35 1.5-ton wagons for the cavalry, and 24 wagons of the same capacity and one postal van for each of the other two divisions. It will be understood that not all of these vehicles were owned by the British government, but were largely of the so-called subsidized class. In ad-



Mechanical Transport in Recent French Army Trials: At Left, Panhard Four-Wheel Drive Tractor Hauling New Siege Gun and Crew; at Right, Part of the Aerial Corps' Vehicles.

dition, there was a column of 10 hired vehicles, not necessarily subject to subsidy, and 30 cars for the use of the Royal Flying Corps, besides ambulances and pleasure cars, the latter being employed by officers.

The French army had a somewhat more pretentious problem. Some 60,000 men were disposed within an area of 20 square miles, and it was the business of each division and sub-division to remain hidden so far as possible. Aeroplanes were employed to search out the hidden "enemy" and to communicate the information learned. Motor vehicles were utilized to transport the aeroplanes, and some of them were fitted as travelling workshops in order that the flying force should be hampered as little as possible in its work.

Quite contrary to the plan in Great Britain, the automobile division was expected to avoid the main highways as much as possible and to convoy its charges without detection. These charges included not only the aeroplane hangars and paraphernalia, but the machine guns, wireless telegraphy outfits, searchlight equipment, etc.

About a year ago the French army gave a preliminary test to a Panhard four-wheel drive tractor for hauling machine guns over rough ground. Seven of these were utilized in the recent manoeuvres, as well as others of the Latil make. Each train consisted of four vehicles; the tractor, an ammunition wagon, the gun and a second ammunition wagon. Each trailer wagon had a brakeman, and the rear vehicle carried the gun crew of from 10 to 15 men. The guns were of a new type, and it was estimated that each train supplanted from 25 to 30 horses.

Practically all the motor vehicles, including the gun trains, were sent across country and over crooked roads at various speeds, and in one instance they descended a 10 per cent. grade about .75 mile in length, only to take a hill of about the same length and with a 13 per cent. grade. Every attempt was made to have the conditions as nearly as possible what might be expected in time of war.

The one exception to the general rule was that of the wireless telegraphy cars. These were of the Delahaye make and worked in pairs, the first being equipped with the dynamo and transmitting current to the other, on which the wireless set was installed. They were called upon to do some cross country work, but only of the very easiest character. It may be added that this is a new type of vehicle with the French army, and is still regarded as in its experimental stage.

Twenty-four converted motor 'buses, of the usual De Dion-Bouton and Schneider types, taken from the regular Paris service, were utilized for transporting fresh meat and supplies of that character. The apparent object was to demonstrate that these vehicles might be available for such service in the event of war. Smaller vehicles were utilized by the headquarters staff as travelling offices. Several pleasure cars also were used by the officers. In fact, the demonstration was about as near horseless as it would appear possible to bring about with an armed force in the field.

GENERAL NEWS FROM ABROAD.

'Buses in South Africa—It is understood that the Municipality of Pretoria in South Africa is in the market for two motor omnibuses.

More Spanish War Vehicles—King Alphonso of Spain has issued a decree authorizing the minister of war to purchase, without formality of calling for bids, 40 40-50 horsepower motor trucks, with accessories, each with capacity of four metric tons.

Ambulances in New Zealand—The Wellington Hospital Board, Wellington, New Zealand, is making inquiries with a view to substituting motor ambulances for the present horse drawn vehicles. A company is being formed in that city for the operation of a motor 'bus line to serve the Pongaroa road.

Additional Motor Mail Vans—So successful has been the plan for utilizing motor vehicles in extending the mail service in the interior of England, that additional bids have been posted for a service between Doncaster, Rotherdam and Sheffield. The distance to be covered weekly is 255 miles, and the estimated load capacity must be 1300 pounds.

Studebakers on Display—During the recent 21st annual exhibition of the Grocery, Provision, Oil and Italian Warehouse Trades Association, held in the Agricultural hall, Islington, England, 11 machines of various load capacities were displayed by four manufacturers, as follows: Studebaker Corporation, Studebaker, three; Dispatch Carrier Company, Girling, three; Consolidated Pneumatic Tool Company, C. P. T., four; R. G. Motor Company, R. G., one.

No 1914 Olympia Display—The Society of Motor Manufacturers & Traders of Great Britain has decided against the holding of a commercial vehicle display at Olympia, London, next year. This action was forecasted, although there was some hope on the part of newer manufacturers of this type of vehicle that the objections would be overcome. It would appear that the only organized showing of motor trucks and wagons in England during 1914 would be that in Manchester in January.

Motor Train for the Czar—The Czar of Russia has just taken possession of a motor train kitchen, built for him in Germany. The train is composed of two vehicles, one of which is the kitchen proper and the other might be termed the pantry. The kitchen is equipped with a stove with five burners, a boiler, a refrigerator and cupboards for the imperial silver. Twelve seats can be fitted into place in a few minutes. The other vehicle, which accommodates eight or 10 persons, has receptacles for carrying provisions, and the seats are so arranged that they can be made up into a very comfortable bed on short notice.

New Commercial Car Accessories

A. A. S. Fibre Tubing.

Hard fibre tubing may be utilized for a number of purposes, such as carrying the high-tension wires, making bushings, etc. Being tough and flexible it permits of drive fits without danger of breaking and it also may be machined and cut easily. The American Auto Supply Company, 1741 Broadway, New York City, and 1408 South Michigan avenue, Chicago, is marketing hard vulcanized fibre tubing, which comes in 24-inch lengths and inside diameters of 1.125 and 1.5 inches. The thickness of the walls is .09375 inch. It is inexpensive.

Apco Anti-Rattler.

The Auto Parts Company, Providence, R. I., maker of Ford specialties, has brought out a new accessory for eliminating the play in the ball end of the steering arm. The device is adjustable. It replaces the usual steel cap on both ends of the steering gear connecting rod, which, when adjusted by filing the halves of the ball socket, usually results in the part binding when the wheels are turned. This is due to the difference between the worn, flat and round part of the ball. The Apco device consists of a bronze shell adjusted by means of a screw plug in the base. The shell member also contains a spring, which holds a steel stud in contact with the ball, resulting in a cushioning effect, and thus in easier steering. The new device is moderately priced.

Doxameter.

The Doxameter is manufactured by the Doxameter Company, Chicago, and differs from the conventional types of devices fitted to the intake pipe of a motor in that it is controlled by the accelerator. It is claimed that by its use not only is the supply of fuel controlled, but a considerable saving is effected as well. It is held that it facilitates combustion in that complete vaporization of the gasoline is made possible. A plunger member, controlling the amount of air, is connected to the accelerator mechanism.

The-Tell-Tale Gasoline Gauge.

Any device saving time makes for economy with commercial vehicles. The Bundy-Goebel Manufacturing Company, Detroit, is marketing an ingenious device for indicating the amount of fuel in the tank, which may be read at a glance. The-Tell-Tale gasoline gauge is not only compact, but it is stated that it may be fitted to the tank in less than two minutes, and after after installation requires no attention. The use of the device does not interfere with replenishing the supply of fuel as the liquid is poured through it, a filler cap of neat appearance being provided. The gauge is oval, one section comprising a calibrated face, over which moves an indicating hand. The-Tell-Tale gauge is constructed for different types of cars and is inexpensive.

Weld Extra Jet.

A device termed the Weld extra jet and designed to make easy the starting of the motor without priming in cold weather is being marketed by the Weld Manufacturing Company, North Chatham, Mass. It is controlled from the seat, a small, compact lever being employed, which may be actuated by the foot. The principle of the extra jet is that of providing a rich mixture for starting and operation until the motor has become sufficiently warm to operate efficiently under the normal mixture. The Weld differs from the usual types of priming devices in that the fuel is completely vaporized, properly mixed with air and conveyed to the intake manifold in proximity to the cylinders, thereby eliminating opportunity of condensation through long contact with the cold, metal walls of the intake pipe. The extra jet takes gasoline from the float chamber of the carburetor, and as the opening is above the level of the fuel, leaking is not possible. The size of the extra jet is approximately .75 by 3.5 inches. Connection from the jet to the actuating handle is by means of a small brass chain. It is stated that it is attached without soldering, only two small holes being required for an .125-inch pipe. In addition to making for easy starting, it is pointed out that the adjustment of the carburetor will not require changing to enrich the mixture for cold weather starting.

Typhoon Horn.

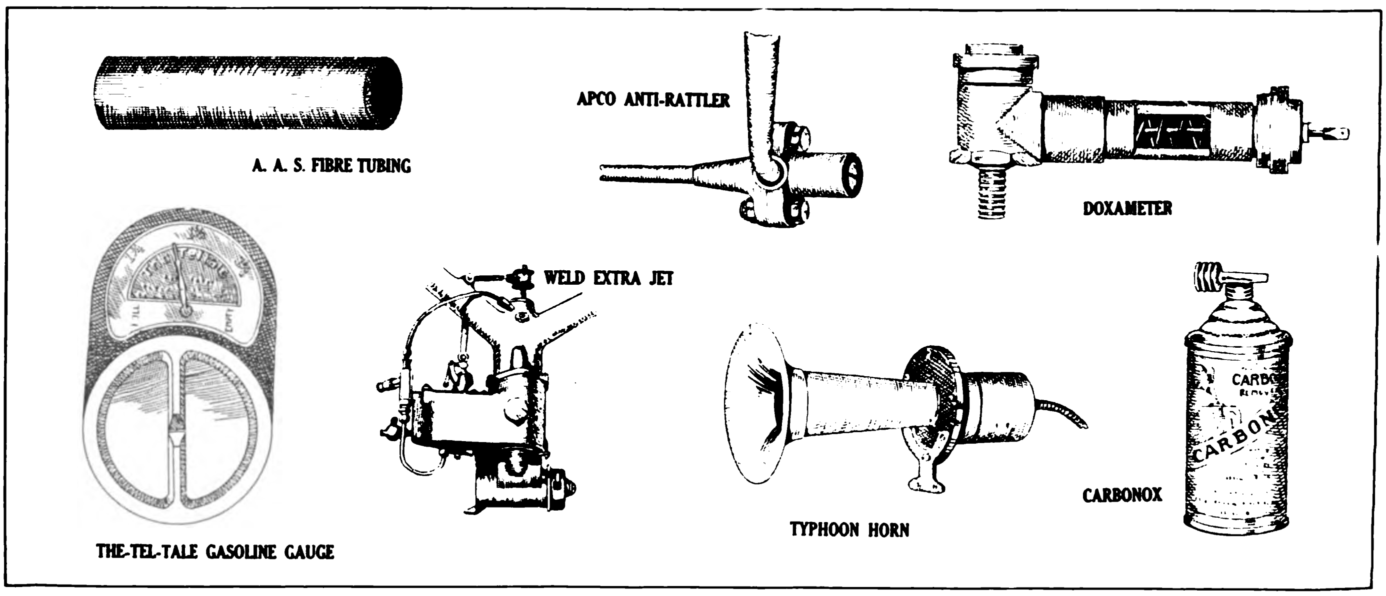
The Typhoon Signal Company, Chicago, is marketing a new style of Typhoon electric horn known as type F, and, although moderately priced, it is sold with a very liberal guarantee. It is made in two designs. One is for mounting on the outside of the machine and has a six-inch projector. It is finished in three styles, all black enamel, nickel and black enamel, and brass and black enamel. The other design is for placing under the hood and is equipped with a long projector to project the sound. It is finished in all black. The company points out that short circuitng is prevented by the use of a 7.5-inch flexible tubular connection for wiring to the horn, and that the construction eliminates the conventional need of terminals. The tone of the new signal is said to be very clear and penetrating and may be operated on any standard six-volt battery. The equipment includes full length wire cable and push button.

Carbonox.

The Northwestern Chemical Company, Marietta, O., is marketing Carbonox, which is a chemical carbon remover. It is stated that it does not dissolve the carbon, but attacks the charred oil that secures the flakes of carbon to each other and to the metal. By destroying this it is possible to blow out the deposits with the exhaust. To use, about half a pint is divided evenly among the cylinders by pouring it through the spark plug openings. It is allowed to stand for about 15 minutes, after which the engine is started. A detachable spout is supplied with each container and Carbonox may be injected into the cylinders much in the same manner as with an oil can, by exerting pressure on the bottom of the can.

Dayton License Number Holder.

The Dayton Malleable Iron Company, Dayton, O., is manufacturing two new designs of license plate holders. The front style comprises two right angle arms, also a clamping construction, fitting around the filler member of the radiator. The securing device differs from conventional design in that it is made to clamp around oblong or round filler members. It is locked by a bolt and nut. The rear design is made with a combination socket, permitting its use with either round or flat lamp irons. Both styles are adjustable.



Illustrating Some of the More Recently Announced Accessories Applicable to the Commercial Vehicle, Repair Shop, Etc.

THE A B C OF MOTOR TRUCK IGNITION.

Part XV—Explaining the Construction and Operation of the Remy R L Magneto, an Inductor Type, Having a Single, Stationary Winding, and Producing a Low-Tension Current Which Is Transformed by a Coil.

By C. P. Shattuck.

AS PREVIOUSLY stated the inductor type magneto may be either a direct high-tension or a primary armature type. An example of the true high-tension magneto was shown in the K-W instrument, the components and operation of which were fully described and illustrated. It will be remembered that with this direct high-tension magneto a single ignition system is provided in that the motor is started by electricity supplied by the instrument itself. It operates on the inductor principle, but instead of a single-wound armature a double is employed; that is, a secondary winding is utilized to transform the low-tension current into a high.

Advantages Claimed in Inductor Type.

The inductor type of magneto was long employed by the Remy Electric Company, Anderson, Ind., and it differs materially from the K-W in that a dual system of ignition is provided, a set of dry cells or a storage battery furnishing current for starting and as an auxiliary source of energy. Advantages claimed for the instrument are: Dual ignition with one set of spark plugs; the elimination of rotating windings, sliding and wiping contacts and collector rings, and a very hot spark. Another feature of the Remy magneto is that the break of the platinum contact points can be adjusted from the exterior of the cam housing and with the motor operating. This enables a quick adjustment, as well as permits the operator to note easily the results of his work.

The simplicity of the producing elements is shown at Fig. 80, which illustrates the principle involved. It will be noted that the winding is mounted between two inductors and that two leads extend from the winding. The latter is of coarse wire (primary), and this member is stationary at all times, being rigidly mounted between the pole pieces, to which are fitted permanent magnets. To a solid ground steel shaft are secured two simple inductors of laminated steel, one on either side of the winding. This shaft rotates on ball bearings and at each half-turn of the inductor shaft, the direction of flow of the lines of magnetic force through the winding is reversed, producing in it two electrical impulses for each complete revolution. The current obtained, therefore, is of an alternating nature.

Construction of Inductor.

The model R L Remy is shown at Fig. 79. It is a two-double-magnet instrument, weighing 21.75 pounds; is 7.5 inches long and 4.1875 wide over all. The stationary winding is held to be absolutely proof against oil, water and grease and, as it is stationary, it is not subjected to stresses. The inductors are built up of steel laminations, insulated to prevent eddy currents, and are balanced by the use of non-magnetic material to eliminate bearing strains. The magnets are of the best grade tungsten steel.

The electricity generated is transformed into a high-tension current by a transformer or step-up coil, the stationary winding being directly connected through the magneto circuit breaker with the primary of the coil. The primary circuit is mechanically broken as with other instruments, by the separation of two platinum points in the cam housing, the break

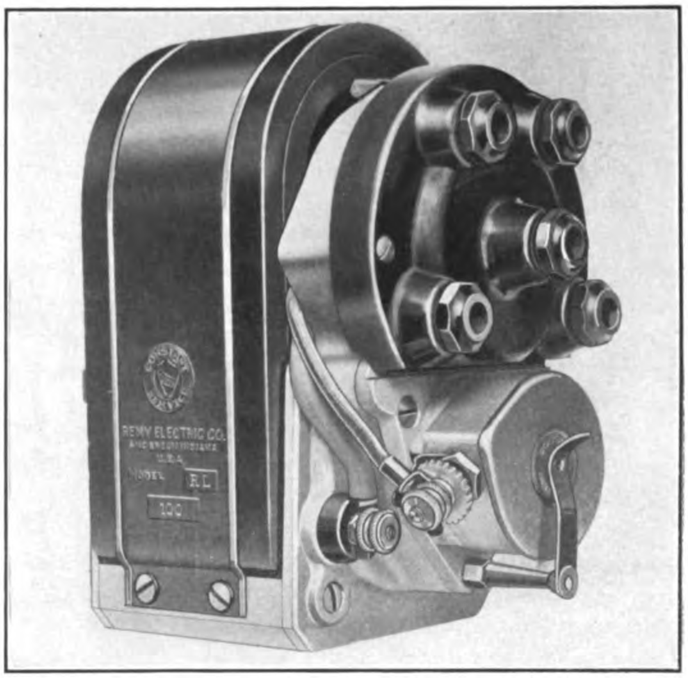


Fig. 79—Remy R L Magneto, an Inductor Type, Having Stationary Winding, and Generating a Low-Tension Current Which Is Transformed by a Coil.

taking place when the current has attained its highest value or efficiency, at which time the spark occurs at the gaps of the plugs. Variation in the time of the spark is possible, as the circuit breaker mechanism may be moved around the inductor shaft, to which is attached the circuit breaker cam. This operation of moving the housing is termed advancing and retarding the spark, the latter being utilized for starting and the advance for operating. The timing range is 35 degrees.

Operation of Magneto.

With the magneto supplying current, that is, the motor operating on electricity generated by the in-

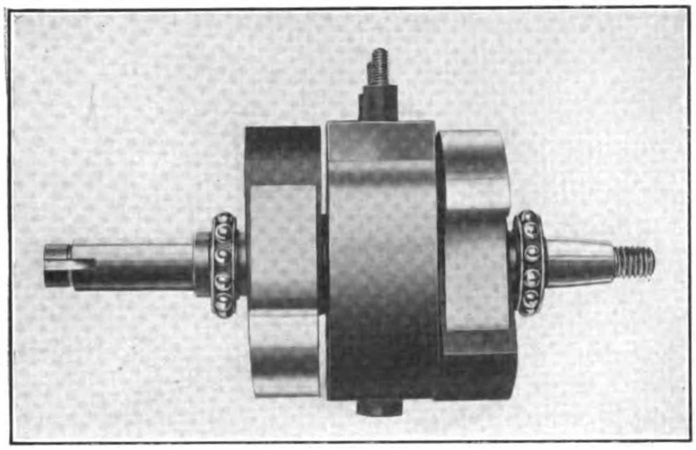

Fig. 80—Showing the Stationary Winding Between Laminated Steel Inductors, Inductor Shaft and Ball Bearings.

strument, the primary current is interrupted or the circuit broken twice every revolution of the inductor shaft. Each revolution, therefore, results in two high-tension impulses, as the magneto current is transformed by the coil and led to the distributor of the instrument by a single cable of sufficient size.

The distributor is actuated by a gear, this member being of bronze, and, with the four-cycle, four-cylinder magneto, twice the size of the driving gear mounted on the inductor shaft, so that the distributor segment will complete one revolution to two of the inductor shaft, as two complete revolutions of the motor crankshaft are made to obtain four impulses. These facts are of importance and have a distinct value, in that they must be considered in the installation and timing of the magneto. Similar gearing is employed for magnetos utilized with one, three and six-cylinder, four-cycle engines.

Components of Distributor.

The distributor of the Remy magneto is made of a well tried, heat resisting, insulating material known as Bakelite. It is non-hygroscopic and has an exceedingly high dielectric strength. The brass distributor segment, or that member conveying the transformed current from the coil to the proper terminals of the distributor housing, is molded in Bakelite and securely attached to the distributor gear. The small gear on the inductor shaft is of steel, the combination making

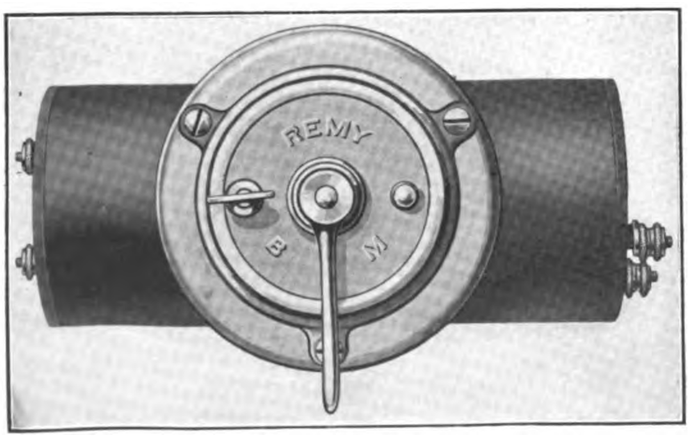

Fig. 81—Switch Utilized with Remy R L Magneto and Having Starting Button, Lock and Key.

for quiet operation, as well as for durability. These components are readily accessible by removing the distributor proper, which is also constructed of Bakelite. The condenser is enclosed in a metal case located in the arch of the magnets.

The circuit breaker mechanism is shown at Fig. 82, and the simplicity of the design is apparent at a glance. It comprises a housing which is free to move through a range of 35 degrees by means of a lever, which is connected by suitable rods, etc., and actuated by the spark lever on the steering wheel. Attached to the inductor shaft is a two-point cam, and in the illustration one of these projections is shown in contact with a pivotally mounted lever and in such manner that the lever is depressed, causing a platinum point mounted on the other end of the lever to move away from a fixed member secured to the cam housing. Each complete revolution of the inductor shaft causes the movable platinum point to make and break contact with the other member twice.

The fixed platinum member is adjustable, but is insulated from the metal of the cam housing and this insulation is secured by lock nuts as shown by the shaded sections of the drawing. Integral with the

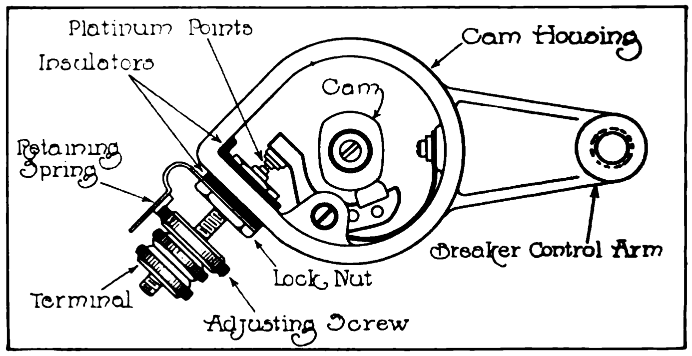

Fig. 82—Showing the Components of Circuit Breaker and Members Utilized in Making Adjustments—The Break May Be Regulated with the Motor Operating.

screw member is an adjusting screw having notches into which fits a retaining spring. The last named member prevents the screw from vibrating out of adjustment, but does not interfere with the rotation of the screw in either direction. A terminal is also fitted to the screw and is utilized for securing a primary lead, as will be noted in the wiring plans presented at Figs. 83 and 84.

Operation on Batteries.

When dry cells are employed, the battery current flows through the transformer coil and circuit breaker, being distributed to the spark plugs by the distributing mechanism, during which operation the magneto current is grounded. The transformer coil and switch are a unit, as will be noted by reference to Fig. 81, and with this arrangement only the switch appears on the operator's side of the dash. It will be seen that the switch lever may be moved to three positions, "neutral", "battery" and "magneto". It will also be seen that a push button is provided in the switch, and with the lever thrown to the battery side, pressing the button creates a spark, in that the primary circuit is closed

by the action. A high-tension current will continue to jump the gap at the plug as long as the button is depressed and the batteries supply current. It is assumed that when the motor stops the distributor is in a position to permit the high-tension current to pass to the terminal connecting with the spark plug of the cylinder on compression.

Direction of Drive, Etc.

The Remy magneto is designed to be operated in one direction only, and must be positively driven either clockwise or anti-clockwise, the direction being indicated by an arrow on the driving end of the inductor shaft. In installing, care must be taken not to have the cap screws or studs project more than .5 inch into the magneto base. Drive by an Oldham coupling is recommended by the maker.

Magnetos employed with four-cycle motors must be driven or geared at the following speeds: Two and four-cylinder, crankshaft speed; three-cylinder, three-quarter crankshaft speed; six-cylinder, 1.5 crankshaft speed. With two-cycle motors: Two-cylinder, crankshaft speed; three-cylinder, 1.5 times crankshaft speed; four-cylinder, double crankshaft speed; six-cylinder, three times crankshaft speed.

Timing the Magneto.

In timing the magneto, the motor is cranked until the piston of the first cylinder (that nearest the radiator with a four-cylinder engine, for example,) is at the top of the compression stroke. A timing button is provided at the top of the distributor and the magneto shaft is rotated by hand until the plunger of this button is felt to drop into a recess on the distributor gear. This device saves the operator from removing the cover to note the position of the segment, etc. With the magneto in this position the driven shaft is connected to the driving member. When secured in this manner the distributor segment is automatically brought into the correct position and will be in contact with the No. 1 terminal. The high-tension cable from the distributor terminal marked No. 1 is then connected with the cylinder having its piston on compression. The remaining wires are installed according to the firing order of the motor. In fitting the wires it should be remembered that the distributor rotates in a direction opposite to that of the inductor shaft.

Wiring Plan of System.

The wiring of a four-cylinder installation is shown at Fig. 83, it being utilized with the L E switch and coil. That at Fig. 84 is a six-cylinder installation. It will be noted that the wires employed are colored, a red lead going from the coil to the ground terminal on the magneto, a yellow to the contact screw on the cam housing and a green to an insulated screw post as shown in the drawing. The three colored wires of the primary cable must be connected with terminals of similar color on the coil. The battery connections are outlined in the diagrams and the various connections and path of the currents should be easily traced with a little study.

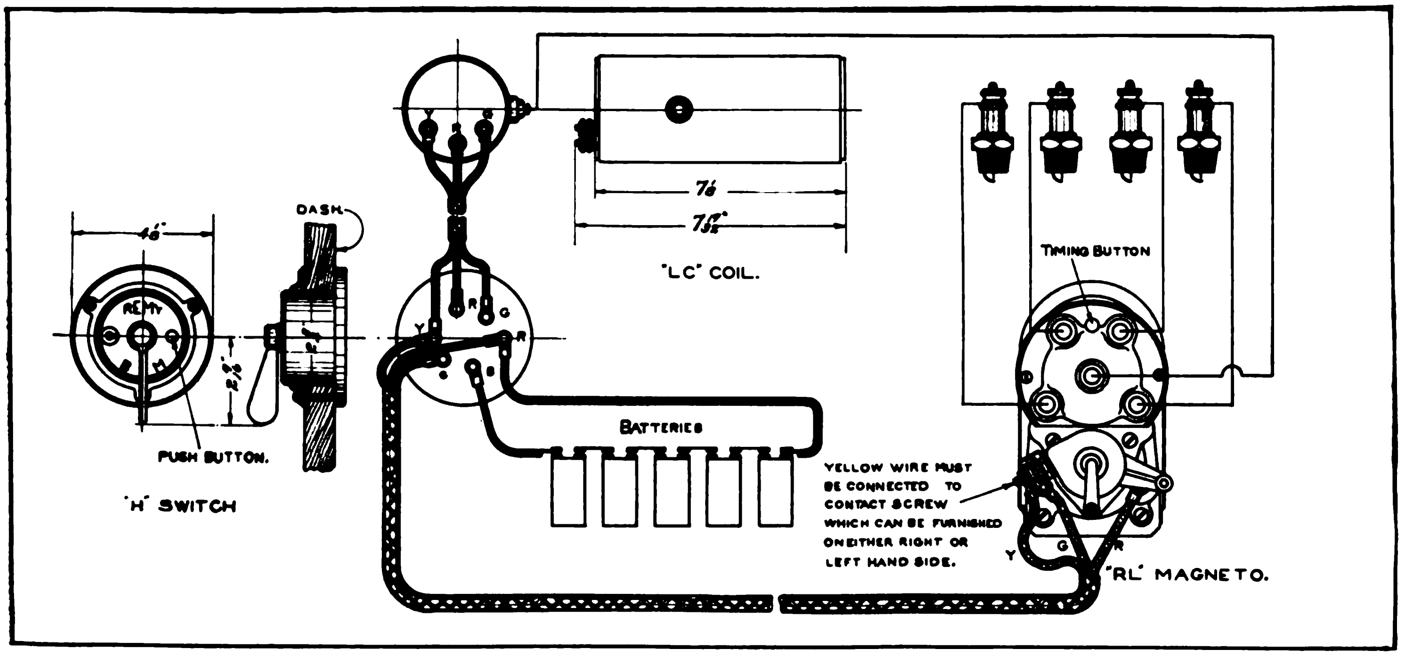

Fig. 83—Wiring Diagram of Remy R L Magneto for Four-Cylinder Motor with H Switch and L C Coil—All Connections and Wires Are Colored to Simplify Installation.

Battery Voltage.

Either a six-volt storage battery or five dry cells connected in series may be utilized, and either side of the battery may be connected to either coil battery terminal. If other electrical apparatus is utilized on the machine, and requires a ground connection, the grounded side of the cells should be connected to the coil battery terminals marked R with the L E coil or to the red wire of the two battery wires projecting from the type D switch. Although the circuit breaker control arm is supplied on either side of the cam housing as convenience demands, in every case the yellow wire must be connected to the platinum pointed contact screw.

Gap of Spark Plugs.

The maker recommends that the gap of the spark plugs be set to a definite point, from .025 to .03 inch.

If the motor misses when running idle or under light loads, the gap may be increased slightly and the result noted. If the motor shows a tendency to miss at slow speeds and under heavy loads the space should be decreased.

To obtain the best results from the magneto the gap between the platinum circuit breaker points should be from .02 to .025 inch, although variation may be made to meet the requirements of the motor. The adjustment of the points is obtained by pressing the retaining spring outward and rotating the adjusting screw. The points should have a smooth surface, as well as be clean. They are readily accessible by displacing the cam house lid, or the cam house may be removed as a unit. Dirt or grease should not be allowed to accumulate on the points, which will require attention but once or twice during an entire season of service.

In rewiring the magneto, all leads should be kept from contacting with or coming near the exhaust manifold or pipe. The high-tension leads—those running from the distributor to the spark plugs and from the coil to the magneto—should be kept separated. If the wires are retained in a metal clamp it is best to utilize some insulation between the metal and the cables.

Lubrication.

Two oilers are provided, one at the rear of the magneto and the other just back of the top of the distributor. Each of these should receive about two or three drops of lubricant every 1000 miles. A good, light oil is best and flooding should be avoided.

(To Be Continued.)

Ed. Note—The next installment will deal with the Mea true high-tension magneto, which differs materially from conventional design in that rocking magnets are utilized, etc.

AUTOMOBILE SCHOOLS MERGED.

The West Side Young Men's Christian Association Automobile School, at Eighth avenue and 57th street, New York City, has absorbed the New York School of Automobile Engineers, at 146 West 56th street, New York, and they are now one institution, being located at the Y. M. C. A. school. The equipment has been consolidated and the facilities are now adequate for meeting practically any requirements made upon the school. The students enrolled in the New York school are now completing their courses in the Y. M. C. A. classes. The West Side school is one of the oldest, as well as the largest, in America, and the New York school was establishd in 1905. It was an excellent institution from every viewpoint.

The direct interest of truck owners and users in the Y. M. C. A. school is in the fact that it has arranged to give special instruction for drivers for service with trucks built by the International Motor Company. With the merging of the two schools a three-ton Mack machine was placed at the disposal of the motor truck department for giving students instruction in road driving, and the school now has the following International equipment: Saurer chassis, motor and clutch, Saurer transmission gearset and Saurer carburetor; Mack chassis, Mack motor, Mack clutch, Mack transmission gearset, Mack axle and Mack carburetor.

With the use of this equipment the students will have special knowledge of the Mack and Saurer machines of practically all sizes, and it is expected that this will make possible training that will be specially valuable. The school has numerous demands for men trained to have special knowledge of vehicles, and the International Motor Company has supplied the means for giving its customers the benefit of drivers who know Mack and Saurer machines thoroughly.

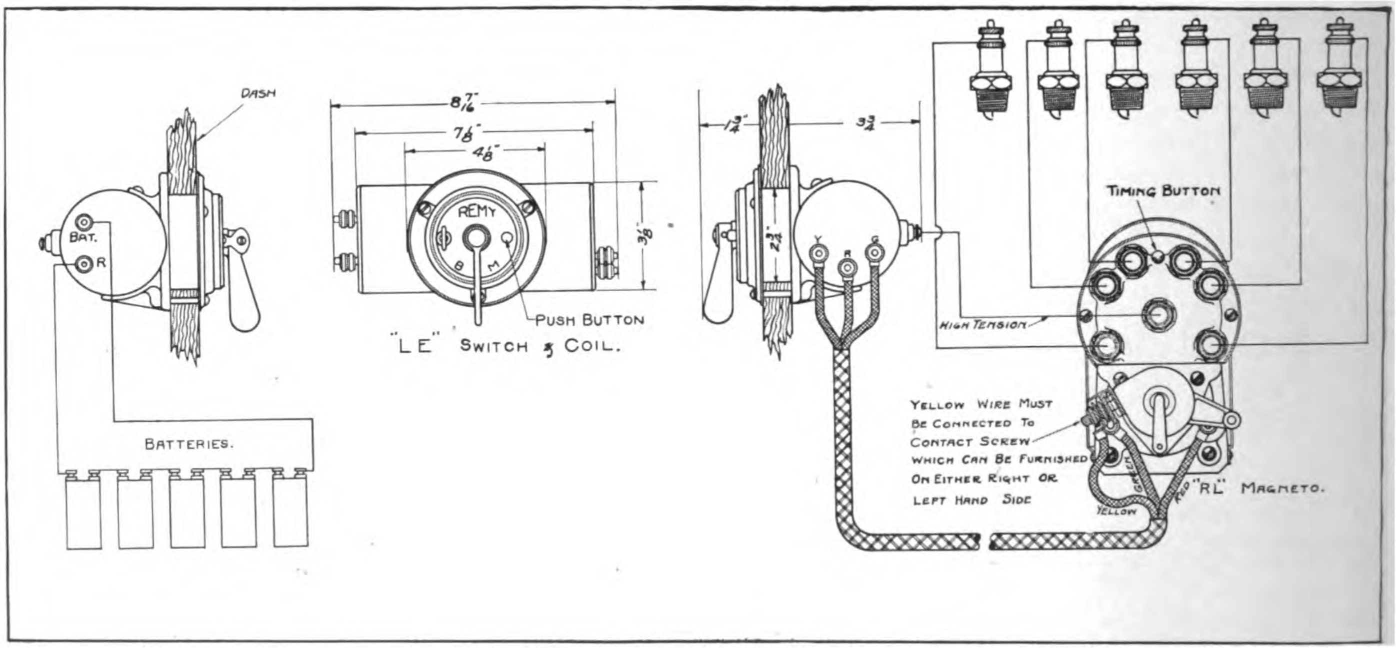

Fig. 84—Wiring Plan of Six-Cylinder Remy Magneto, Including L E Coil and Switch—In Connecting Leads from Distributor Terminals to Spark Plugs, Firing Order of Cylinders Must Be Observed.

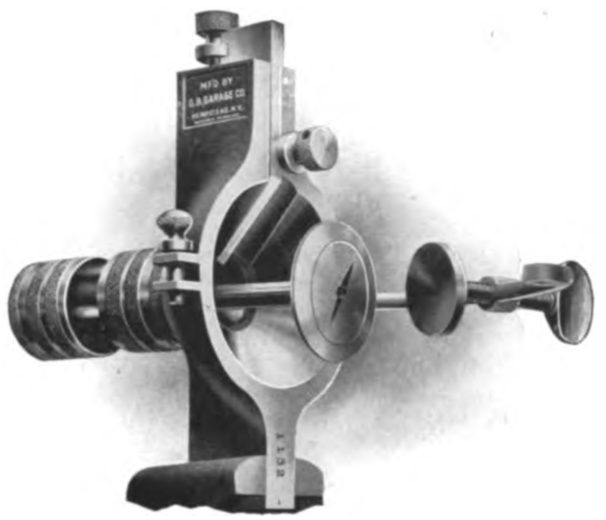
GARAGE AND SERVICE STATION EQUIPMENT.

THE G. B. Sales Corporation, 1790 Broadway, New York City, is marketing the G. B. valve tool shown in an accompanying illustration, and the maker



G. B. Valve Tool

states that not only is considerable labor saved, but economy effected.

The equipment is for reseating as well as redressing the valves, and the maker states that it will reface valves to a perfect angle of 45 degrees and may be utilized with those of any size and material. The tool is so constructed that the valve must always be on centre when it is being dressed, insuring a uniform face. The device is also serviceable when ridges, grooves, pits, etc., are to be removed and which take considerable time when ground by hand.

The G. B. tool is the invention of George C. Bouthinon, who has had considerable experience in the manufacture of motor cars, and he designed it to save time in the factory. It is of drop forged, case hardened steel, the blade and seat cutter being of high speed, oil tempered tool steel, and guaranteed against defects in material and workmanship.

To use, the tool is clamped in the vise, a bridge member opened, and the blade disengaged by loosening a lock screw. The valve is then placed in the cone section and the knurling nuts turned to equalize the distance on both end threads, so that a roller bearing will be flat on the valve stem. The knurling lock nut is secured and the bridge closed, the latter being retained by a pin member. The blade is then adjusted and locked. The valve is rotated by a dog and feed is by thumb screw. The blades and cutters are sharpened easily.

LINDHE SHIMS.

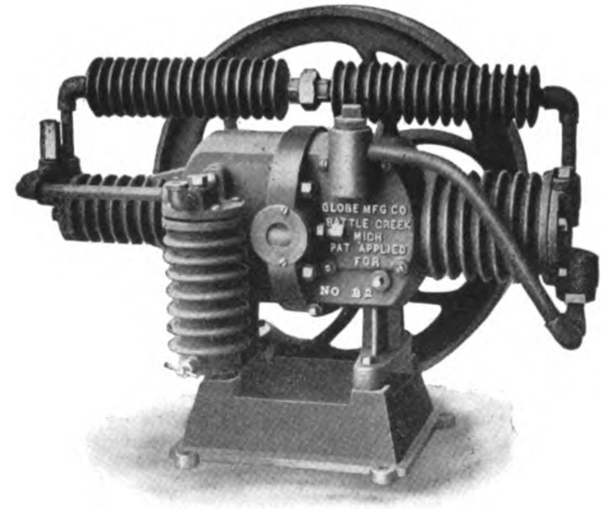
The Lindhe Shim Company, 212 Canal street, New York City, is marketing the Lindhe shims in two new sets. The first is known as the No. 1 and comprises one strip, .03125 by two by nine inches (all .002 inch laminations); .0625 by two by nine inches; .125 by two by nine inches; half the last two named are .002 inch laminations and half solid brass. The second set consists of similar sizes, excepting the laminations are .003 inch. By combining these different pieces almost any thickness of shim can be obtained.

MILLER STEAM VULCANIZER.

Charles E. Miller, Anderson, Ind., is marketing the Five-In-One steam vulcanizer, which has a circular surface and essential clamps for repairing eight tubes at the same time. The circular tube plate has four extensions for casings. The gas or gasoline burner is stationary, but the vulcanizer proper may be rotated as desired. Air bags are eliminated, as the outfit is operated with pad and clamp pressure.

GLOBE AIR COMPRESSORS.

Air compressors are a valuable addition to the service station and garage, as they may be utilized for a number of purposes. The Globe Manufacturing Company, Battle Creek, Mich., is marketing a line of air compressors to meet the requirements of service, including stationary and portable outfits. All are of the air-cooled type and it is stated that stuffing boxes, oil cups, piston packings, etc., are eliminated, and that all working parts are fully enclosed. One of the compressors is shown in an accompanying illustration and when in operation will develop and maintain 150 pounds or more pressure. The company also produces an automatic outfit, which keeps the tank constantly



Globe Air-Cooled Compressor Especially Constructed for Garage Service, Etc.

stored at a predetermined pressure. The company issues a catalogue in which are listed 20 types of compressors and each equipment is fully explained.

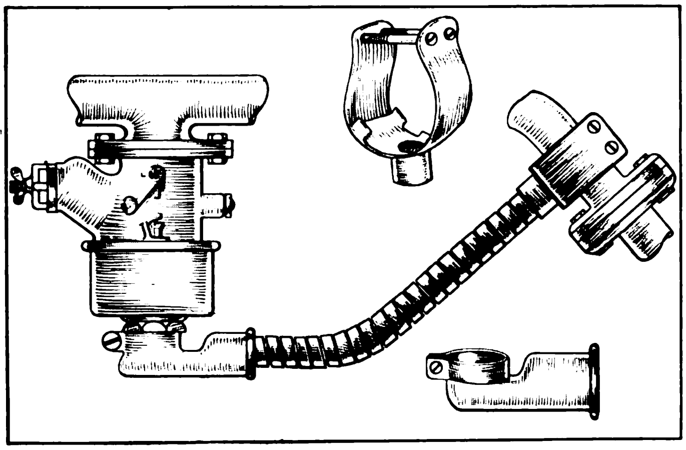
CORRESPONDENCE WITH THE READER.

Hot Air and Carburetion.

(50)—I would like some information on the use of hot air with the carburetor. Is there any advantage in heating the air and how does it affect the mixture? Can hot air devices be used with any type of carburetor? How is the device installed? Does it make starting any easier in cold weather? What is the best anti-freezing solution to use?
MOTOR TRUCK READER.
Burlington, Vt., Oct. 25.

Heating the carburetor may be by one of two methods; either by circulating the hot water around the mixing chamber or conveying heated air to the air intake. The latter method is becoming more popular, many car makers employing a flexible tubing for conveying the heated air of the exhaust pipe to the air inlet.

To understand the function of the heated air and its proper application, it should be borne in mind that the air drawn into the carburetor by the suction of the piston, passes over the spraying nozzle and the vapor is mixed with it, creating what is termed the mixture. The more perfect the mixture the quicker it burns and the more complete is the combustion. Rapid evaporation of the fuel is desirable and it is important that the mixture reach the cylinders without the value being changed, or without condensation.



Illustrating the Col-Mac Utilized for Conveying Heated Air to the Carburetor and the Connections.

It is held by one maker that the air should be taken as free from atmospheric moisture as possible. He maintains that dried air will absorb moisture, that of the vapor, much more quickly and more perfect carburetion is obtained as a result. Taking in dried, warmed air results in a slight expansion, but not to a harmful degree, as the cold of the vacuum in the mixing chamber absorbs the heat and contracts the air quickly to less than its original volume.

In an accompanying illustration is shown the Col-Mac hot air device attached to a carburetor and the connections are also outlined. In this instance a hood like device is secured to the exhaust pipe and by means of a flexible pipe secured to a clamp, it is possible to utilize the heat given off by the exhaust pipe. The Col-Mac is produced in sizes, etc., to meet the requirements of different installations, and the maker, the Breeze Carburetor Company, Newark, N. J., will supply details on request. It is necessary to mention the make and size of the carburetor and model of the car.

The use of hot air aids in starting a cold motor only after the initial explosions are obtained. It requires but little time for the exhaust gases to heat the walls of the pipe and it is obvious that any raise of the temperature results in facilitating the evaporization of the fuel. Another advantage is economy. When the car is not equipped with a pan or undershield, the hot air attachment prevents the entrance of foreign elements. The various anti-freezing solutions are discussed elsewhere in this issue.

Fitting Priming Cups.

(51)—I have a converted pleasure car, the motor of which is not fitted with priming cocks. The centre of the cylinder heads has a removable plug and provides an opening into the combustion chamber. Would it be practical to fit priming cups to this opening and what would be the approximate cost? The exhaust valve caps are too thin to use. INFORMATION.
Toledo, O., Oct. 14.

If the plugs referred to are of sufficient diameter, they could be drilled and tapped to take the priming cup. Priming cups are inexpensive and may be purchased from 20 cents to $1.50, depending upon their design. They may be obtained from any supply house. They are made in .125 and .25-inch pipe threads, with straight and angle shanks, also long and short. In fitting these members care should be taken to make them gas tight. The cost of preparing the plugs for the priming cups should be slight and the work could be performed in the garage.

Erratic Running Motor.

(52)—I am operating a 1000-pound delivery car and lately have experienced trouble with the motor acting queerly. With the spark and throttle set in one position and running on the level, the car will speed up, then slow down. Then, again, it will run all right. Have been over the ignition and it appears all right. Tank is clean and I have drained carburetor. The trouble is not steady, which puzzles me. What would cause this trouble? J. A. C.
Toledo, O., Oct. 10.

From the description it would appear that the trouble is due to the fuel supply; that either the pipe leading from the tank to the carburetor was partially clogged, or that a particle of dirt sticks in the spraying nozzle. Another cause may be that the float sticks at times, causing a dearth of fuel in the float chamber.

Shut off the fuel at the tank and disconnect the pipe at the carburetor. Next turn on the gasoline and note if it flows freely through the tubing. If so, the carburetor should be cleaned. Disassemble it and clean thoroughly, noting if the spraying nozzle is clean. Fill the float chamber with gasoline and note if the float is at the proper level and if it moves freely.

Use of Camphor in Fuel.

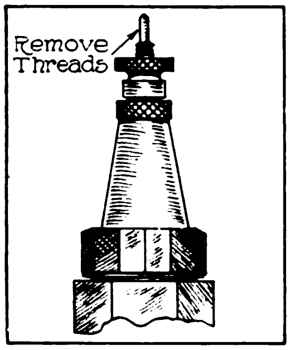
(53)—Will use of camphor in the fuel increase the efficiency of the motor and would you advise its use? SUBSCRIBER.
Chicago, Oct. 28.

According to tests conducted by an English engineer with two types of machines, there was no noticeable difference in the work of the engines nor was the mileage increased.

HINTS FOR PROPER MAINTENANCE.

IN ADJUSTING bearings of the ball type care should be taken not to have them too loose or too tight. In taking up lost motion considerable judgment must be exercised in screwing up on the adjusting member, not to get this too tight and impose an injurious end pressure on the balls. An excess pressure that will stress the bearing parts dangerously will not make much difference in the wheel resistance when turned by hand, though when the car weight must be sustained at high speeds or when going around corners, the resistance will be increased materially and bearing endurance reduced proportionally.

A safe rule to follow is to take up the wear by screwing in on the adjustment nut so that the shake or looseness will be eliminated, yet permit the wheel to spin for a few revolutions when given an initial impulse. Many drivers and even inexperienced mechanics commit the error of adjusting bearings of the take-up type too loosely. This is not desirable, any more than fitting parts too loosely together. Always lock adjustment nut firmly in place when the proper adjustment has been secured.



A Spark Plug Kink.

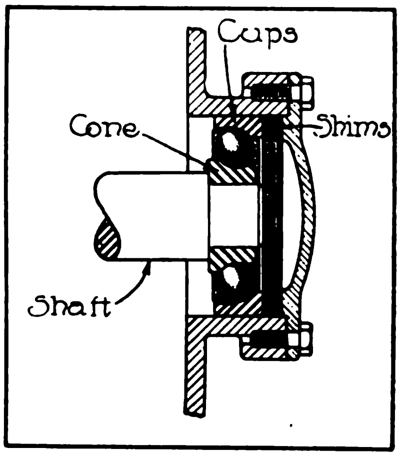
In some gearboxes and axles the bearings are shim adjusted. A number of thin washers of sheet brass may be interposed between the bearing cup and retainer cap, as shown in an accompanying illustration. When taking down an assembly of this nature always keep the shims from any bearing box together and tagged for future identification, to insure that the adjustment made in the factory will be maintained in the reassembly. If the bearings are loose for any reason, add shims about .005 inch thick to the others, until there is no appreciable lost motion and yet no binding between bearing parts. The above is an abstract from the ball bearing manual issued free by the New Departure Manufacturing Company, Bristol, Conn.

ADJUSTABLE TESTING SEAT.

Where there is more than one car to be cared for, an adjustable seat for testing the chassis out on the road after the overhaul is of value. In an accompanying illustration is presented a sketch of an easily made seat which can be constructed in the garage, and with very little trouble may be adjusted to fit any chassis, and shifted to accommodate either right or left hand steer.

The top member of the seat is constructed of a suitable length and thickness of plank, which is cut in two, the cut being made three or four inches from the centre, as shown. The side members or standards are of .875 or inch board and the top boards are screwed onto these. To prevent sidesway, angle irons are fitted, two to each standard.

The seat is made adjustable by boring two holes in the smaller boards and cutting two slots in the larger member as shown. Two mild steel plates .25 inch thick and nine long, with width equal to that of the plank, are employed to secure the two halves, bolts passing through the plate and slots in the seat. Four bars of .5 or .625-inch round iron and about eight inches longer than the seat overall, are threaded and fitted with nuts and washers. Four holes are bored in the side standards at a suitable pitch to allow the rods, when in position, to clear the chassis frame.

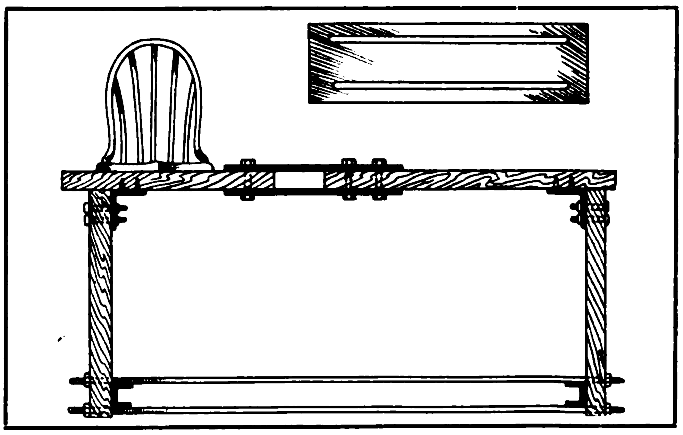


Shimming Ball Bearings.

To fit the seat to a chassis, it is placed in position, the rods fitted over and under the frame as shown, and the nuts screwed up snugly. As the bolts in the plates will slide in the slot during the fitting, these members should be loose while the seat is being placed on the chassis, but they are tightened in position after the rods are secured.

SPARK PLUG HINT.

The majority of drivers have experienced the annoyance of hunting for a nut, bolt, etc., that has fallen into the motor pan when making an adjustment of a part. The spark plug terminal is frequently a source of trouble in this respect. In an accompanying illustration is presented a suggestion for making it easy to start the terminal. Two or more of the top threads are filed off carefully, permitting of slipping on the terminal and catching a thread very easily.



An Inexpensive Testing Seat Adjustable to Any Chassis and Quickly Attached.

MARTIN & HUNEKE FUEL STORAGE SYSTEM.

A STORAGE system for handling volatile, inflammable liquids, which differs from conventional practise and presents many interesting features, is the

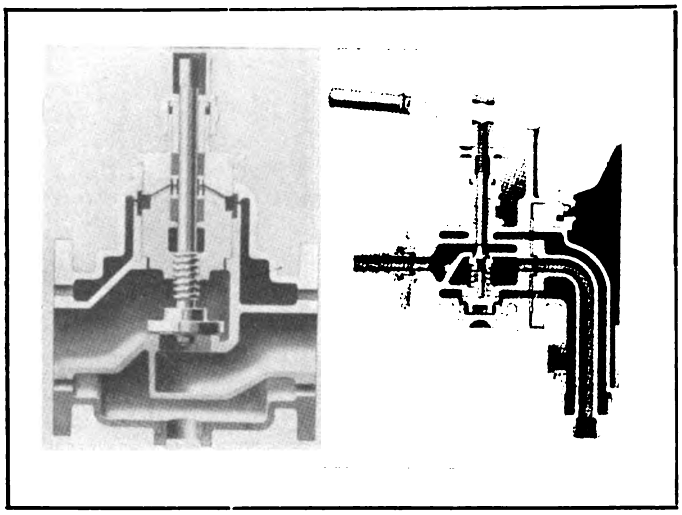


Fig. 1—Line and Draw-Off Valve Utilized with Martini & Huneke Fuel Storage System.

Martini & Huneke safety system, marketed by the Martini & Huneke Company, Woolworth building, New York City, which concern is affiliated with a large number of companies abroad where the system has been employed for the past eight years. As the application of the system is so varied only a general outline is given herein, but installations are made to meet varying requirements, whether for a manufacturing plant or a garage. The company maintains a corps of experienced engineers and is prepared to submit plans and specifications.

The most prominent features of the system are the means employed to prevent loss by evaporation, protection against fire or explosion and manner of handling the fuel, even when the main container is being filled. Another interesting feature is that leaks are instantly noted, it being possible to verify at once the normal operation of the system.

Throughout the apparatus in which the liquid is stored or handled, air is replaced by carbon dioxide (commonly known as carbonic acid gas) or other inert gas, which not only determines the movement of the liquid, but also serves as a protecting agent. This gas fills the jackets of all the pipes and valves, acting in such manner that the liquid can circulate only when the system is absolutely free of leaks. For example: If a leak occurs, the pressure of the gas will disappear and the liquid will remain in the tank, where there is no danger of explosion, since air is necessary to the formation of an explosive mixture.

The principle of the Martini & Huneke system is shown at Fig. 2, it comprising a storage tank of heavy sheet steel buried in the ground, inlet and outlet valves, a cylinder of compressed inert gas for protecting the liquid and for forcing it through the pipes, and jacketed pipes connecting the different parts of the system. The components shown are as follows:

1, storage tank, 2, 3, 4 and 5, anti-diffuser; 6 and 7, jacketed pipe connection to draw-off valve; 8, jacketed intake pipe; 9, carbon dioxide cylinder; 10, high pressure gas line to regulator; 11, pressure regulator; 12, low pressure gas line to storage tank; 13 and 14, jacketed draw-off valve; 15, mercury manometer; 16, liquid intake valve; 17, gas valve for equalizing pressure; 18, syphon for emptying drum; 19, shipping drum.

To charge the storage tank it is first filled with inert gas, then connected to the drum by means of a jacketed pipe and syphon. The pipes are provided with two valves, through one of which the liquid is syphoned into the storage tank, while the other permits gas from the storage tank to replace the liquid in the drum as fast as it runs out. This prevents any liquid left in the drum from coming into contact with the air and forming an explosive mixture.

The pressure of the gas in the main tank determines the height to which the liquid rises in the piping system, while the annular jacket space surrounding the distributing pipes is always in communication with the inert gas in the storage tank and assures an instantaneous return of all the liquid contained in the piping in case of any leak. In either case the liquid returns to the storage tank by gravity. As a further protection each pipe entering the tank passes through an anti-diffuser, which device serves as a safety valve, preventing the inert gas from leaving the tank and being replaced by air in the event the piping system is destroyed by fire. All of the outer pipes are fitted with fusible plugs, which melt at a low temperature, insuring a return of the liquid to the tank.

To draw the liquid it is only necessary to press the lever of the discharge valve shown at the right in Fig. 1, the fuel immediately rising through the jacketed pipe, owing to the pressure of the gas, and it con-

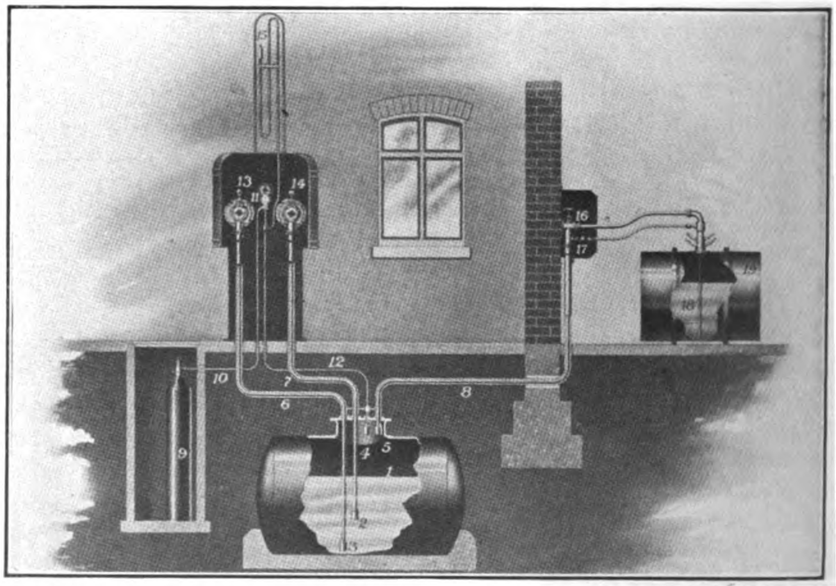

Fig. 2—Components of Martini & Huneke Storage System Employing Inert Gas and Having Many Interesting Features.

tinues to flow until the lever is released. The jacketed pipes referred to include an inner tube having three or more longitudinal ribs to keep the walls of the two pipes apart. The anti-diffuser operates on the principle of the Davy safety lamp; its upper part being filled with wire gauze admits either liquid or the gas, but prevents the passage of a flame into the tank. The bottom of the device is cupped to prevent diffusion of the gas in the tank after pressure has been reduced to that of the atmosphere, it being filled with liquid.

For small installations carbon dioxide gas, readily obtained, is utilized, but with large systems a special apparatus is supplied for producing an inert gas. A charging panel is also supplied, containing one or more inlet valves and connections, and a receptacle for the gas cylinder is included. Special measuring apparatus can be furnished to suit requirements as with conventional fuel storage systems. The Martini & Huneke system is also constructed for tank wagons and other carriers of inflammable liquids.

LIMITS MOTOR TRUCK WEIGHT.

Rules Restricting Capacity and Speed Now Effective in New York State.

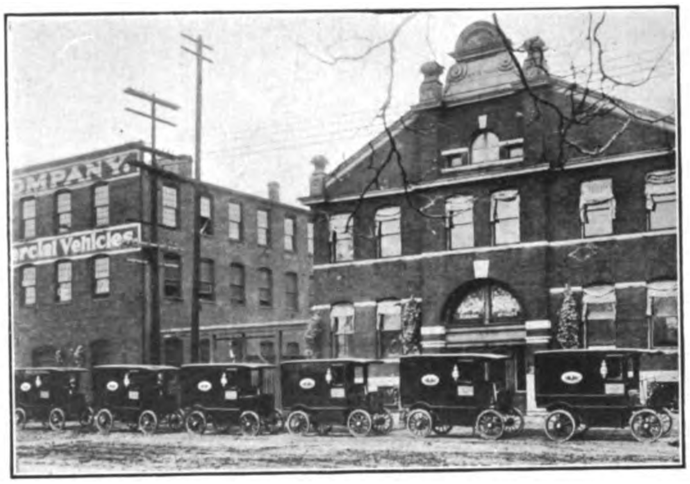
Rules promulgated by the commissioner of highways of New York State became effective Oct. 20, and these will obtain until they have been suspended by the same official, the regulating authority being conferred upon him by law. The rules provide that no tractor or traction engine, motor trucks or other power vehicle shall be driven on the roads if the wheels are fitted with cleats, flanges, rings, etc., to afford traction, but traction engines may be permitted to use cleats not less than 2.5 inches width and 1.5 inches thickness on all four wheels if not less than two cleats contact with the ground at the same time, and the weight is equally distributed on the cleats.

No power vehicle or traction engine or road roller that weighs more than 14 tons shall be used without a permit obtained from the state commissioner, this weight including both vehicle and load, and not more than eight tons shall be carried on one axle. The tires of the vehicles, aside from the exception noted, shall be smooth and the weight of the vehicle and its load shall not exceed 800 pounds for each inch of tire width. Permission to exceed this weight may be obtained.

The width of a motor vehicle is limited to 90 inches, but traction engines may be 100 inches. No vehicle carrying a weight of more than four tons, including the vehicle, shall be driven faster than 15 miles an hour, and no vehicle carrying a weight of more than six tons shall be driven faster than six miles an hour when fitted with metal tires, nor faster than 12 miles an hour when fitted with tires of other material than metal. The state commissioner may, at request, grant special permits to move vehicles weighing in excess of 14 tons subject to such prescriptions as may be imposed. Those violating the regulations shall be responsible for all damage to the highways and the value of the damage may be recovered by an action of tort brought by the state commissioner or the county or town superintendents of highways in the towns where the violation is noted.

CENTRAL STATION HAULAGE.

The New York Edison Company has just added six 1000-pound Waverley delivery wagons, equipped with panel bodies, to its transportation equipment, these being of a type that has been proven to be economical in delivery and maintenance work. The Waverley company has recently sold vehicles of the same class and power to the Edison Electric Illuminating Company of Boston, the Cambridge, Mass., Electric Light Company, the Commonwealth Edison Company of Chicago, Ill., the Denver Gas & Electric Company, the Louisville Lighting Company, the Merchants' Heat & Light Company of Indianapolis, the County Light Company of Pittsburg, the Duquesne



Six 1000-Pound Wagons, with Panel Bodies, Delivered to the New York Edison Company by the Waverley Company.

Light Company of Pittsburg, and the British Columbia Electric Railway Company of Vancouver, B. C.

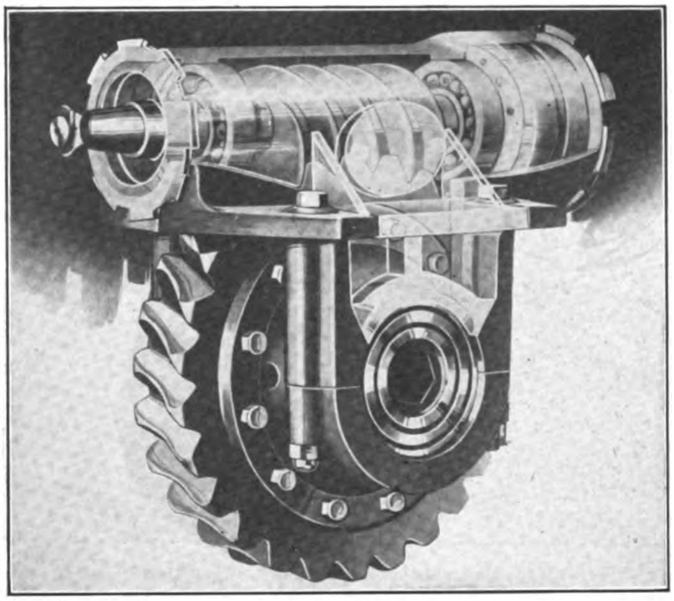
The experience of the Waverley Company is that there is a steadily increasing interest in electric vehicles with the central stations, and many of these firms are preparing to motorize their transportation departments, to say nothing of the constantly growing demand from business men and industries for machines that can be used in all kinds of urban haulage service. The possibilities of sale of current for charging purposes have received a great deal of attention from the public service corporations, and the practical promotion from use of electric machines has been taken up by a surprisingly large number of these concerns.

The Argo Electric Vehicle Company, Saginaw, Mich., which has experimented with electric tractors for upwards of two years, has perfected the design and will shortly begin the commercial production of these machines.

SHELDON WORM DRIVEN AXLES.

THE Sheldon Axle Company, Wilkesbarre, Penn., manufacturer of vehicle axles, springs, wheels and chassis parts, is now building a worm driven axle intended for wagon and truck service. This axle will be produced in several sizes for use with different types of vehicles. The demand for a power transmission system eliminating a second reduction of gearing has caused the use of the propeller shaft, and there is a limitation to the possibilities of this type of drive because of the extremely large size of the bevel gear when the reduction is greater than 4:1. The worm drive, however, permits a very wide range of reduction.

The worm and wheel of the Sheldon axle, together with the mounting of the differential, is shown in the accompanying phantom view illustration. In this it will be seen that three teeth of the gear wheel are al-



Phantom View of the New Sheldon Worm and Worm Wheel System of Transmission.

ways in engagement with the worm, and emphasis is made that with this construction there is greater strength than with the bevel gear, where but one tooth at a time takes all the weight of the load. The contact being sliding the worm and wheel drive is practically noiseless.

The Sheldon construction is non-adjustable. The carrier must be machined accurately to assemble the worm and wheel, and once assembled it is not adjustable, and can be removed and replaced without changing its alignment. Its efficiency increases with slight gradual wear. Worms and worm wheels have a minimum life of 80,000 miles, and when so worn that efficiency is impaired they can be replaced at moderate cost. As shown in the illustration the worm is mounted on two imported annular ball bearings and the end thrust is taken by a heavy duty double-thrust bearing. The differential is made of alloy steel and is of a size sufficient to enable it to endure under all loads. It is mounted on double-row annular bearings.

The axle housing is a single-piece casting of best grade steel. In testing the strength of a one-ton housing it was supported on 37-inch centres and a 50-ton weight deflected it .0625 inch. The casting resumed its original form with the removal of the weight. The high elastic strength of the steel, which is figured as about 80,000 pounds to the square inch, proved that the section modulus is more than equal to any stress that might result from road usage, and affords a factor of safety of at least 10:1 on the elastic limits of the material.

The Sheldon worm drive axles are a semi-floating type, in which special attention has been given the axle shafts. In the one-ton type they are 2.375 inches diameter at the critical point and made of 3.5 per cent. nickel steel, and are given a double heat treatment. The shaft end that fits the differential case is hexagonal, a construction that increases the section modulus of the shafts.

Both brakes, as with all Sheldon standard equipment, are on the rear wheels, the drums being 14 inches diameter and 2.5 inches face. The brakes are internal expanding and external contracting, the latter having special means of adjustment. Hubs for either steel or wood wheels are supplied, the tendency being to use the steel equipment. The company states that in England, where the worm drive has been used for years, the London General Omnibus Company uses 2700 omnibuses equipped with this type of drive. The average life of the worm drive with these vehicles is 83,000 miles, and one has been driven 124,000 miles.

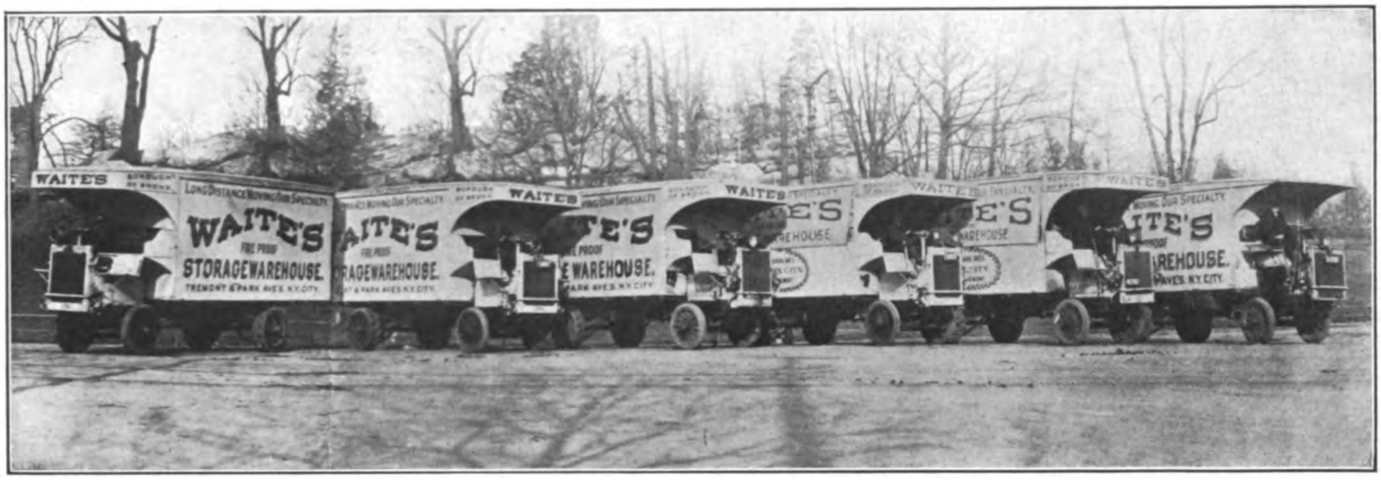
Robert S. Woodford, Jr., president of the concern, and S. Lawrence Bodine and Thomas L. Gaskill have been appointed receivers of the Standard Roller Bearing Company of Philadelphia, Penn., upon petition of the First National Bank of Philadelphia, and the assent of President Woodford has been given. The inability of the company to pay the interest or principal of its floating indebtedness and the refusal of a New York bank to renew a maturing loan is given as the cause. The purpose is to continue the business, for the statement is made that the assets exceed the liabilities and by conservative management the creditors can be paid in full and the interests of the stockholders protected. The company produces steel balls, ball and roller bearings and Rudge-Whitworth wire wheels. At the plant of the company at Philadelphia more than 1000 persons are employed.

The stockholders of the Reo Motor Car Company, Lansing, Mich., are to receive 60,000 shares of stock of the Reo Motor Truck Company, valued at $600,000, which was held by the former organization. The stockholders of the Reo Motor Truck Company recently received a dividend of seven per cent.

LONG DISTANCE FURNITURE HAULAGE.

Development of a Metropolitan Warehouse and Moving Business to Successful Competition with Rail and Water Lines Within Radius of 200 Miles with Motor Vans.

THE development of the business of Waite's Motor Van & Storage Company, at Tremont and Park avenues, Borough of the Bronx, New York City, by the use of motor trucks, is a striking example of the possibilities of transportation economy through specialized service, and the willingness of the people to take advantage of what is to them a decidedly better means of conveyance. This company is a competitor with railroad and steamer lines within a radius of 200 miles of New York and because of decidedly superior handling of freight carried it not only attracts patronage, but commands prices for the work that are very profitable. In other words, the company transfers household furnishings from one house to another within the radius stated and insures that the property will be hauled and delivered without loss or damage, and the delivery is so greatly expedited that a removal of residence is an undertaking of comparatively small proportions.



Six of the Fleet of Seven 3.5-Ton G. M. C. Trucks in the Service of Waite's Moving Van and Storage Company, Borough of Bronx, New York City.

Less than three years ago the company's business was confined to New York City and vicinity, all its work being done with horses, but with the acquisition of motor trucks its activities were extended, and it is now prepared to go to any point that may be desired, there being no limitation other than the price that must be charged for the special service that is afforded. Each year the radius is extended and hauls are made as far east as Providence, R. I., and to Philadelphia, Penn., and Wilmington, Del., at the south, while trips to Springfield, Mass.; Hartford and New Haven, Conn.; Trenton, N. J.; Poughkeepsie, N. Y., and other intermediate points are made very frequently. Removals of from 40 to 75 miles are as common as were those of a dozen miles with animals, and the majority of hauls of 100 miles are completed and the return made within the 24 hours. An example of service is the loading of a van, a haul of 189 miles, and the delivery of the freight in 19 hours, this work being done with a crew of a driver and two men, though the maximum crew of a truck is five. No attempt was made in this instance to make a record, but after loading the machine the trip was a straightaway run with stops only for meals and for replenishment of fuel and oil.

The company for years did a business largely in upper New York City, and transfer work was engaged in quite as much as removal of household effects, the establishment of a warehouse for storage in a fireproof building adding a department that attracted some patronage. The Bronx, which is a comparatively small part of New York, but covers a considerable area, is largely a residential section. Many people leaving the city to make residences elsewhere have stored their property, and the combination of transportation and storage attracted business that had previously been divided. Later on the possibility of having delivery made direct to the new home from the store house eliminated numerous inconveniences and personal attention, and the inquiries made from comparatively distant points for such transportation prompted the first purchase of a machine.

To understand clearly the conditions in which the business has been developed the statement should be made that railroad or water freight rates are the minimum that can be secured. In the event of household removal the railroad has practically two services and three rates. The first service is for shipment in carload quantities, which has a specified charge for each 100 pounds or fractional part for the distance. The second service is where less than a car is used and the rate is similarly based. For the first service, however, insurance against loss by theft, breakage, wreck or storm damage can be secured by the payment of a

higher rate. Where carload shipments are made without insurance the car is sealed and the railroad guarantees to deliver the car at its destination, but the owner assumes all risk and the car is supposedly delivered within a reasonable length of time. The haulage may take from a couple of days for 100 miles to a week or more. The car may go astray and delay result. But the contents of the car are not disturbed during transit.

With a partial carload the freight is more or less exposed because the car is opened for the removal of other property at different points, and there is greater possibility of theft or loss or damage, and the transit is necessarily slower from deliveries at several points. This method is less satisfactory than where an entire car is used. In shipment by water lines there is not the same security as with the railroad from the fact that the goods cannot be placed in compartments and the possibilities of loss are considerably greater. One means of protection, that is customary, is crating the property regarded as valuable, which must be done before transfer from the house to the car, and packing is only satisfactory and sufficiently protective when done by experienced men. On arrival at the destination the property must be uncrated, and while this is not so important, the work is considerable. Then to afford the best transportation by railroad the goods should be crated, sent in carload quantity and protected by insurance, and crating and insurance is necessary with water line shipments. Considering time, convenience and expense for a moment it is evident that crating and packing, haulage by railroad or water and uncrating, and the payment of insurance means that the cost will be considerably more than the actual freight rate, to say nothing of the probability of delay and the accompanying annoyances.

With this aspect of the ordinary means of transporting, the possibilities of specialized service, packing goods in large vans that would effectually protect them from dust, water and light, and delivery from the vans to the houses, appeared to be very attractive. Work of this character was done with animal vans within short distances, and the only question was whether the people would take advantage of the service of the company and be willing to pay sufficient charges to justify the investment. President W. A. Waite studied the subject from several angles. Assuming that a delivery was to be made 75 miles distant, this would mean that the price charged must be sufficient to pay for the time of the van and the men, and this must cover 150 miles actual travel for the vehicles and the services of the men; or, viewed from another light, the price for the haulage must cover the services of the men and vehicles, have a margin that would yield a profit and meet any travel exigency, permit insurance against fire, damage or theft while in transit, and yet be such as would be attractive to the public when contrasted with the rates exacted for other forms of transportation.

As stated, the special service would be expected to be more expensive than the ordinary, and the advantages would be the minimized handling, elimination of crates, quick haulage and ample insurance, but in addition the haulage to and from the railroad or water line terminal at either end of the haul would be a considerable item that would have to be added to the freight rates. The division of responsibility in the event of damage is another important factor. The aggregate cost of removal is not represented by the railroad rate, but it was believed that contract jobs would be profitable. There was reason to question the economy of motor trucks in locality transfer work from the fact that the greatest success could only be attained by keeping the machines busy constantly, and idle time would be more expensive with trucks than with animal vehicles. The question was of developing the long hauls and affording service that would justify prices that would be profitable.

President W. A. Waite decided to experiment and to this end in March, 1911, he bought a used 3.5-ton G. M. C. truck and equipped it to meet his requirements as a van. The old body was removed and in its place was installed a van body 16 feet length and seven feet width and height, giving a storage space of 784 cubic feet. The body was substantially built to adequately protect the goods against storm or dust. The walls were solid and the roof made heavy, with a high tail gate and double doors at the rear, so that the van could be locked and sealed. The roof of the body was extended over the dash and the end and sides of the hood or cab lowered so as to make a large compartment for the storage of tools, covers, spare clothing, etc., all convenient to the driver. The seat and footboards were replaced by new construction so that the original space under the seat was preserved, but the seat made wide enough to carry the driver and four men, the seat being the full width of the body.

In designing the van body it was made so that it would carry practically double the quantity of goods that could be carried in a horse wagon, and with a capacity of 3.5 tons the belief was that the machine would seldom be loaded to its rated load. For the purpose of obtaining the greatest advertising value the van was painted white and attractively decorated with gold lettering, and whenever it was sent away a large sign was placed at either side that notified all who might approach within a block that long distance moving was specialized. The machine was placed in service and the work through the spring was so satisfactory that the first new truck was ordered and delivered June 23, 1911. This was equipped with a very similar body, but full length double doors were built for the rear and the decorating was made more ornate and the removable signs were replaced by permanent lettering.

Mr. Waite found with experience that publicity was required, and besides the general knowledge obtained through the regular channels of the business and the appearance of the vehicles in the streets, he began a general distribution of mailing cards, these be-

ing circulated in all sections of New York and vicinity, being sent out by the thousand, and besides serving a very useful purpose in directing attention to his service, these had printed forms so that, at the cost of a penny stamp to sender, a representative could be summoned who could make estimate for any work. The fact that people were disposed to prefer the service given, and that the contracts could be made advantageously was evident from the demands, but the possibility of developing the return trips of the machines, especially when of considerable length and making two profits, was worthy of attention. Mr. Waite directed his attention to this development and in a comparatively short time began to obtain results, and today more than half the trips are with a load in either direction, thus materially increasing the productiveness of the machines.

The third machine was ordered and delivered Jan. 27, 1912; the fourth April 1, 1912; the fifth Aug. 6, 1912, and the sixth Sept. 15, 1912, so that during last year four vans were added to the fleet, these being equipped as were the second. Feb. 25 of this year the seventh van was delivered and all of these are now in use. The prospect is that others will be ordered. As the machines were bought the number of horse vans was reduced, it being found that the trucks could be worked advantageously on short hauls and that sufficient contracts could be made to keep them busy. In fact, during the seasons of the year when people remove from the city to the country or the shore, or vice versa, the vans are worked a great deal of the time, which would not be possible with horses. Mr. Waite has but one team of animals, and these are worked practically all of the time on his farm, and were used but a short time last spring in removal work. With a view of still further increasing the business mailing cards are distributed, lots of 100,000 being sent out frequently.

Of his experience with motor vans Mr. Waite says that they have proven a real success. They have been worked for nearly three years in all manner of conditions and have made all kinds of hauls over roads of all kinds, from the best to very bad. The trucks have, he says, endured wonderfully well, and as a direct result from their use the haulage work of the business was in 1911 increased more than 50 per cent. over that of 1910, and in 1912 was again increased more than 50 per cent. over that done in 1911. This increase he attributes solely to the use of motor vans, for with them he can do work that would not be attempted with horses. In 1912 with five motor trucks more than double the work was accomplished than was done in 1910 with 20 horses, at a saving of 35 per cent. expense, and this year the result will be even more satisfactory because of the longer experience, the better contracts and the more work performed. While this gives the saving as 35 per cent. in contrast with horse work, this year there will be a much larger margin of profit because of the long distance contract work, which could not be undertaken with any other form of equipment, and this has been made more than ordinarily productive through securing return freights.

The Van Bodies of the Waite Trucks, Having Capacity of 784 Cubic Feet, with the Bonnet Affording Storage Space and the Wide Seats for the Crews of Five.

The value of this business cannot be estimated, but it is increasing constantly.

Mr. Waite does not maintain a garage, but keeps his machines in a public service station convenient to his warehouse, paying a flat rate for storage and washing and cleaning. The drivers formerly drove animals and have been trained in handling furniture. They are thoroughly experienced with the work and are capable, responsible men. These men are in charge of each job where they cannot communicate with the office and are expected to economize time and labor wherever possible, and at times the men and their helpers have long, hard trips. Mr. Waite says that a truck van can be driven 40 miles in less time than horses can be driven 20 miles, and will carry double the load. The vans are so large that not infrequently the furnishings of three apartments are carried in one machine, and where conditions will permit two and three jobs are done at practically the same time. The average load will weigh from two to three tons.

The drivers are not required to do work on the machines they drive, but a mechanic is employed who

is responsible for them and who is on call practically day and night. He inspects the machines as they are returned to the garage at night and he is expected to have them in readiness for service each morning. If necessary, he is given assistance in the work on the vans. When a machine is withdrawn for an overhaul the mechanic does the work and such parts as are necessary for restoration are ordered. Mr. Waite believes that this is the most economical form of maintenance for a fleet of the size of his. The records kept are of the mileage, the fuel, oil and grease used, the tire mileage and the cost and adjustments, and the expense of supplies, accessories and parts purchased. The mechanical work and the storage are covered by the wage of the mechanic, unless additional labor is provided, and the garage bill each month. To these charges is added the overhauling and painting.

RECEIVER FOR POPE COMPANY.

Early Maturing Note Issue and Condition of Market Lead to the Appointment.

Col. George Pope was appointed receiver of the Pope Manufacturing Company, Hartford, Conn., maker of Pope-Hartford cars and trucks, by Judge Joseph P. Tuttle of Hartford, Oct. 27. At ancillary proceedings in the United States District Court at Boston Oct. 28, Col. Pope was named as ancillary receiver. Col. Pope is treasurer of the company and has qualified as receiver under a bond of $200,000.

The condition of the automobile market and that the company has an issue of $1,000,000 two-year notes bearing interest at six per cent., which will mature April 1, 1914, led to the application for a receiver, the proceedings being of a purely friendly character. Reports of dissension between the Pope and Walker interests, which have controlled the company, are emphatically denied by President Albert L. Pope, who maintains that the interests of the Walkers and the Popes are identical and in every way harmonious.

The appointment of the receiver will make possible the continuance of the business under the orders of the court, and will prevent complication that might in any way hamper the business. The officials of the company confidently expect that the creditors will be paid in full and that the stockholders will either receive a substantial dividend or will be in a position to realize largely under a reorganization plan, should this be decided on. The authorized capital of the company is $6,500,000, and $3,690,800 common stock and $2,989,200 preferred stock have been issued, leaving 3092 shares of common stock and 2018 shares of preferred stock in the treasury. When the issue of notes was made it was to liquidate a floating indebtedness of about $250,000 and provide additional capital, and a part of the $750,000 was devoted to building an addition to the factory. Under a trust agreement the company has been required to maintain a surplus of $500,000 in quick assets over all indebtedness during the life of the note, and no mortgage could be placed on the property.

The company has a plant at Hartford, where cars and motor trucks are built, and has a bicycle and motorcycle factory at Westfield, Mass. The officers of the company are: Directors, Albert L. Pope, Hartford; George Pope, Hartford; Arthur W. Pope, Boston; Edward W. Pope, Boston; C. E. Walker, Hartford; W. C. Walker, Hartford; H. C. Wiley, Boston; F. A. Drury, Worcester, Mass.; R. M. Currier, Boston; president, Albert L. Pope; vice president, C. E. Walker; treasurer, George Pope; assistant treasurer, E. M. Cutting; secretary, W. C. Walker; assistant secretary, H. A. Lienhard. Col. Pope, the receiver, is a pioneer of the bicycle and automobile industries of the United States and he is treasurer of the Automobile Chamber of Commerce.

Fleet of Half-Ton Commerce Wagons in the Service of the Green-Joyce Company's Department Store at Columbus, O.

The branch of the Goodyear Tire & Rubber Company at Milwaukee, Wis., was recently destroyed by fire with a loss of $225,000. The company has established a temporary branch at 338-40 East Water street, a short distance from the former location.

R. V. Board of Boston has been elected president of the Kentucky Wagon Manufacturing Company, Louisville, Ky., builder of Urban electric wagons, and Philip S. Tuley of Louisville, Ky., is now vice president of the concern. W. C. Nones, formerly president of the company, has been elected chairman of the board of directors.

F. W. SMITH NEW EXECUTIVE OF E. V. A.

Chicago Convention Productive of Well Founded Plans for Promoting the Use of Electric Vehicles—Substantial Publicity Fund Insures Continuity of Campaign.

ENTHUSIASM and a decided spirit of co-operation were manifested at the fourth annual convention of the Electric Vehicle Association at Chicago, Oct. 27-28, and with the largest attendance in the history of the organization at a gathering of this character, the purpose of the officers and members, to systematically promote the use of electric vehicles, was carefully developed and plans for the coming year were matured. This was the first time the association convention had been held west of New York, and through the energetic endeavors of the committees and officers the showing of eastern members was surprisingly large, while the Chicago committee had aroused a very large degree of interest among western men.

Frank W. Smith, President of the Electric Vehicle Association of America.

One of the results of the convention was the opportunity for the different interests to reach definite levels on which the promotive work can be carried on, and to determine policies which would be equally productive for all. The membership was materially increased by the advent of a stronger western representation, and plans were made which will result in the establishment of several additional sections, which will greatly broaden the influence of the association. The organization has now a very substantial foothold in the east and the west, and with the activities of the membership constantly extending, and with concerted endeavors of members who fully understand the benefits to be secured, there is no doubt whatever that the association will be largely increased during the year.

During the convention 351 members were registered and upwards of 50 applications for membership were made, so that with 428 members of record prior to the convention the aggregate is well along toward the 500 mark, which is a growth on which the association may justly pride itself. The plans for the convention were developed by a committee that had abundant time for organization, and the results were in every way satisfying. The eastern delegation was assembled in New York, the New England contingent in part coming from Boston in a party, and left the Metropolis Oct. 26 in a special train under the direction of F. Nelson Carle as master of transportation. The delegates were joined at different points en route and reached Chicago Oct. 26. The headquarters were at the Hotel La Salle, where the convention was held in apartments on the 19th floor, and many of the manufacturers established themselves in rooms on the 18th floor, where small exhibits were made and where the members of firms or their representatives could meet friends and those connected with them in business transactions. The opening of individual headquarters made possible meetings that would have been at least doubtful under ordinary conditions, and was decidedly promotive of relations beneficial to all.

President Williams' Address.

The morning of the first day until 10 was devoted to registration and general preliminary work incidental to the formalities, and then the first session was called together by President Arthur Williams, who made the annual address of the executive. He congratulated the association on the growth made in three years, for it had increased from the 29 organizing members to 418 of record at the opening of the convention, including 34 manufacturers of electric vehicles and 61 central stations. He pointed out that the possibilities for expansion were very large, and that with the association larger than ever before, with precise and well directed activities, and with potent influences constantly exerted for promotion of the industry, the results ought to be very gratifying. The association has sections in New England and Chicago, and local associations in New York and Philadelphia, and live interests are projecting a section on the Pacific Coast.

Mr. Williams believed that the association ought eventually to include in its membership every company operating a central station, and there was a possibility of securing as members every user of an electric vehicle. The prospects for the growth of the electric vehicle industry were very encouraging. The number of manufacturers was now 37 as against 20 a year ago, including both pleasure car and service wagon builders. He pointed out that there were, as established by carefully compiled figures, 37,000 electric vehicles in the United States, and this number was increasing with gratifying rapidity. Turning to the possibilities of the electric, he stated that as about 85 per cent. of the transportation by highway was within the distance zones that made practical the use of such machines, he was extremely confident that the economy and endurance possible through their use would eventually result in their adoption by business men. The certainty of operation and economical maintenance made the electric ideal for fire apparatus and installations where quick starting was essential. He stated

that the heavy duty to which storage batteries could be subjected was well demonstrated by the operation of street cars in New York City, for transportation lines using them were required by demands of the public to afford constant and satisfactory service. The storage battery cars were absolutely dependable.

President Williams emphasized the necessity of attention by the association to the conditions of traffic in some of the large cities, especially New York, where the thoroughfares were so greatly congested during the day that the only practical solution appeared to be haulage by night, with the probable readjustment of transportation, so far as shipping and receiving was concerned, to meet the changed requirements. Were haulage carried on during the night this would eliminate much congestion, and would result in a very large saving of time, as well as reducing the number of vehicles needed. There would be enormously increased efficiency and by the use of electric vehicles the streets would be so much economized that there would be but little delay as compared with what is now experienced. The utilization of electric vehicles in city haulage service offered very extremely attractive possibilities, and the demand for current for vehicles would afford very large incomes for the companies supplying it. If all the haulage were done by electric vehicles in the large cities, only, and the price paid for current were but two cents a kilowatt-hour, the annual income to the central stations would approximate $400,000,000.

Day Baker, Re-Elected Treasurer of the Electric Vehicle Association.

The economic value of the land that is now devoted to raising food for animals was touched upon by Mr. Williams, who maintained that these tracts could be used for food crops, with the consequent reduction of prices and establishing absolutely dependable markets. No loss would be experienced, but there would be a changed condition that would decidedly benefit the people. There was no doubt that the evolution of transportation would mean the adoption of mechanical vehicles and a very large part of these would be electric. The standardization of certain equipment, in the opinion of Mr. Williams, was very important, and should be brought about. He believed that the endeavors of the committee in charge of the publicity and advertising deserved the hearty commendation of every member, and maintained that the promotive campaign planned would be productive of very large returns. One of the essentials for the development of the electric vehicle industry and the promotion of the use of machines was the practical garage, where service could be obtained, and in proportion to the number of those stations, and dependent upon the attention that could be obtained, would be the use of electric machines. What would undoubtedly have a material influence in the sale and use of machines was within the scope of the organization to deal with, and this was the publication of books that would contain maps and reliable information and the location of the different stations where charging could be obtained and repairs be made.

At the conclusion of the paper it was referred to a committee consisting of W. P. Kennedy of New York, E. E. Witherby of Chicago and Hayden Eames of Cleveland, O.

Reports of Committees.

The reports of committees were then received. In the absence of Chairman P. D. Wagoner the report for the legislation committee was made by E. W. Curtis, Jr., of New York, and this pointed out the inclination of legislators to enact more or less radical laws, generally unduly penalizing or taxing the owners of motor vehicles. The efforts of the organizations of motor vehicle owners in opposing objectionable legislation were considered, and the committee pointed out that a New York legislative committee is to confer with commissioners representing nine different states, and eventually with the federal government, with the hope of formulating law that will serve the interests of the public without restricting the utility and economy of the motor vehicle. Standardized laws were to be recommended. The committee was purposed to afford such assistance in formulation of laws as might be necessary, and urged the necessity of opposing unreasonable restrictive legislation.

Chairman W. P. Kennedy made report for the committee on operating records, which was in the form of a tabulation of operating cost that might be submitted as definite and dependable information whenever needed, covering seven sizes of vehicles from 750 to 10,000 pounds, and applicable as average expense. The committee also submitted a general form for recording such operating cost. No specific rate of current cost was specified because of the variance in different localities, but it was stated that the average would be about four cents a kilowatt-hour. As the cost of current is seldom more than 10 per cent. of the operating cost the rate for current was not regarded as of more importance than other factors. The report was discussed by S. G. Thompson of Newark, N. J.; J. S. Codman of Boston, George H. Jones of Chicago, C. F. Smith of Boston, W. H. Conant of Washington, Day Baker of Boston, J. A. Hunnewell of Lowell, E. S. Mansfield of Boston, F. Nelson Carle of New York and Charles H. Marsh of Washington.

For the committee on insurance Chairman Day Baker made report that the committee had secured a 10 per cent. differential rate on electric vehicles that

had been almost universally adopted, and that the committee had further secured from the New England Casualty Company a reduction equivalent to 10 per cent. from the rate first obtained, or practically 20 per cent. from the standard rate for gasoline vehicles and trucks. In the consideration of this report the value of the advertising and of the insurance differential was emphasized by President Williams and Converse D. Marsh of New York.

Harvey Robinson, Re-Elected Secretary of the Electric Vehicle Association.

Favor Education in Schools.

Charles Blizard of Philadelphia presented the report for the committee on the courses of instruction in electric vehicle practise, in the absence of Chairman W. G. Pancoast, which was inaugurated in the West Technical high school of Cleveland, O., the report describing the course in that institution. The educational work undertaken by the Denver Gas and Electric Light Company of Denver was stated by E. M. Jackson of Denver, and he believed a course of vehicle and battery instruction could be promoted by the association. E. E. Witherby of Chicago proposed that a correspondence school be established by the association. E. W. Curtis, Jr., told of the school established by the General Vehicle Company, and Day Baker stated that the technical schools of Boston have begun consideration of the advisability of such a course. The investigation made by the Chicago section was told of by Homer E. Neisz of Chicago.

John F. Gilchrist of Chicago made report for the committee on rates and charging stations, which had obtained data from 128 different central stations. It was shown that the average rate in 91 of the largest cities was 3.007 cents a kilowatt-hour for current supplied to public garages and 5.338 cents a kilowatt-hour for current supplied to private garages. The service inaugurated by the Hartford Electric Light Company, which is practically a battery exchange, the owner purchasing a vehicle without a battery and paying a stated price for the battery mileage used, being relieved from all maintenance, was described. The committee expressed itself as being much interested in the commercial result of the service. The report was discussed at considerable length.

President Williams named as a nominating committee George H. Jones of Chicago, E. W. Curtis, Jr., R. L. Lloyd of Philadelphia, E. S. Mansfield of Boston and Charles Blizard of Philadelphia.

Papers and Discussions.

At the opening of the afternoon session reports were made under the subject "What the Sections Are Doing", by Homer E. Neisz of Chicago, J. A. Hunnewell of Lowell for the New England Section, Harvey Robinson for the New York Electric Vehicle Association and Day Baker for the Electric Motor Car Club of Boston.

"Co-Operation Between the Electric Vehicle Manufacturers and the Central Stations" was the subject of a paper by E. L. Callahan, vice president of the commercial section of the National Electric Light Association, who contrasted the results to be obtained by the electric vehicle manufacturer and the central station from the promotion of the use of electric cars and wagons. He maintained that the manufacturer benefits by the better satisfaction of vehicle users, the improvement of operating conditions, the use of more machines and the advice as to prospective purchasers, while the central station benefits from increase of revenue, the advertising from the use of the vehicles and the general social and industrial progress of the community. He was of the opinion that the charging rates prevailing in most cities were reasonable, and pointed out that recently in a city of 325,000 people the vehicle charging rate was established as 3.8 cents a kilowatt-hour for the first 1000 and was reduced by a sliding scale for subsequent consumption. Investigation has shown that the cost of charging current was seldom 10 per cent. of the operating cost. He maintained that the revenue from an electric flat iron equalled the original sale price in about 4.5 months, while the revenue from a vehicle was about six per cent. of its cost annually.

The paper was discussed by Converse D. Marsh and S. G. Thompson of Newark, N. J., who insisted that the central stations should at least share the expense of vehicle selling, as the average revenue was about 300 per cent. of the cost of securing the business. Day Baker called attention to a "Handbook of Electric Vehicles", written by F. S. Smith and H. C. Cushing, Jr., of New York, as containing valuable data and information. H. H. Rice of Indianapolis was of the opinion that the possibilities of profit to the central station should be explained by the vehicle manufacturers to secure co-operation. He maintained that the neglect of the electric machine in the garage, rather than its use on the streets, was the most general cause of dissatisfaction.

A decidedly interesting paper on "The Merchant, the Central Station and the Electric Truck" was read by F. Nelson Carle, advertising manager of the General Vehicle Company. He maintained that the central station was a potent educational and industrial influence in the community, in which the people had confidence, and it was a logical advocate for the electric machine, and for this reason it is asked to assist in promoting, through advertising and other publicity, its use. The reason for asking this was that by central station aid the first cost of distribuiton would be

reduced and the expense brought where it would promote rather than restrict production. He emphasized the prestige of the central station in the community, the fact that it has minimum advertising rates, that its publicity is interesting and productive of confidence, and that its good will can be a great factor in the sale of electrics. He believed the greatest single educational force behind the electric vehicle to be the Electric Vehicle Association, and next to this rated the work now being done by the central stations in a number of the large cities.

"Traffic Problems and the Automobile" was the title of a paper read by Dr. E. E. Pratt, manager of the industrial bureau of the Merchants' Association of New York City, which was a very careful summary of the conditions obtaining in New York, which can be applied very generally to other large cities, with suggestions for remedies that might be desirable. He maintained that while there could be regulation of the street traffic, the congestion at freight terminals could not be reduced until a system could be developed that would make possible the delivery of freight at the terminal nearest the consignee. The physical terminal should be so developed as to give the truck of the consignee rapid and efficient service. He believed that the solution would be best made by a commission of experts appointed by the city or state which would be charged with studying, first, the sources of accidents arising from automobiles; second, the wear of the street surfaces due to automobile traffic, and, third, the whole subject of traffic delays on streets and at terminals and docks.

Adjusting Garaging Rates.

The third session was opened the morning of the second day by the presentation of the report of the garage committee, which had been appointed to investigate conditions and attempt to arrange local rates for the charging and care of electric vehicles throughout the country, and which had appointed local committees to make investigation and recommendation, the reports of which were included. The committee had proposed that manufacturers of vehicles and parts cooperate with the committee by offering public garages repair parts at such discount as would make possible the sale of parts at the same prices as sold by the manufacturers' agents, and permit a reasonable margin of profit, but this had been found impracticable with many because of the agency agreements. This paper was followed by discussion on the subject of discount for repair parts.

David F. Tobias of the United Light and Power Company, New York City, read a paper on "The Electric Vehicle in Department Store Service" in which the installation of Gimbel Brothers in New York City was described at length and the efficiency of the service was considered. C. A. Duerr, manager of the Gimbel Brothers garages, told of the satisfaction obtaining with electrics and stated that with an experience of three years there was no doubt the electric vehicles were both practical and economical.

S. C. Harris of New York read a statement relative to vehicle batteries that had been made to another association, in which care of batteries was generally considered.

M. R. Barry of the Electric Products Company, Cleveland, O., presented a very interesting paper on "Charging Storage Batteries in Unattended Garages". This was followed by a paper on "Electric Vehicle Salesmanship", a consideration of the possibilities of well organized selling campaigns, by George H. Kelly and E. J. Bartlett of the Baker Motor Vehicle Company, with suggestions for co-operative promotion by the vehicle manufacturer and the central station. A paper of unusual interest on "Recent Developments in the Lead Battery for Electric Vehicles" was read by Bruce Ford of the Electric Storage Battery Company.

Frank W. Smith Elected President.

The election of officers resulted in the unanimous choice of the recommendation of the nominating committee, which was as follows: President, Frank W. Smith, United Electric Light and Power Company, New York City; vice president, John F. Gilchrist, Commonwealth Edison Company, Chicago; secretary, Harvey Robinson, New York Edison Company, New York City; treasurer, Day Baker, General Vehicle Company, Boston; directors, Arthur Williams, New York Edison Company, New York City; William P. Kennedy, New York City; William G. Bee, Edison Storage Battery Company, Orange, N. J.; Clare N. Stannard, Denver Gas and Electric Light Company, Denver, Col.

The Closing Session.

The afternoon session of the second day was devoted to the reading of a paper on "Electric Commercial Vehicle Tires" by F. E. Whitney of the Commercial Truck Company of America, which subject aroused keen interest, and to the presentation of the report of the publicity and advertising committee, which was read by President-elect Smith, the chairman. The result of the first year's promotive campaign was briefly reviewed, and the statement made that it had been productive of about 2000 direct replies to advertising, aside from the other promotion. The campaign of the Society for Electric Development conflicted with the collection of funds for advertising, but with few exceptions all the larger central stations renewed their subscriptions. At the time the report was compiled the number of subscribers totalled 107, an increase of five as compared with the previous year, and the amount of subscriptions was $34,046.38, received from 82 central stations, 10 battery and accessory manufacturers and 15 vehicle builders.

Of the subscriptions 54 per cent. came from central stations, 31 per cent. from battery and accessory manufacturers, and 15 per cent. from vehicle builders. Of the first year contributors 39, including five vehicle manufacturers, have not thus far contributed, so that the list for the 1913-14 campaign contains 47 names that are new. Most of these are central stations.

The plan for the second year involves an expendi-

ture of $33,422.28, which will be carried on through general magazines, fashion and social publications, central station prints, automobile trade journals and a fifth group of three specialized mediums. The estimate includes the publication of two booklets, "The Story of the Electric Pleasure Vehicle" and "The Story of the Electric Commercial Vehicle", which illustrate the productions of the manufacturers who are contributors to the fund. The booklets will be distributed in response to inquiries, and can be utilized by central stations as part of their advertising literature at comparatively small expense. The detail of the general plan of the campaign was included in the report.

The session was closed with a talk by Ralph Temple of the Temple garage, Chicago, whose subject was, "How to Make the Business Healthy".

The evening of the first day a beefsteak dinner was served to the delegates at 6 o'clock, and the early part of the evening was given over to an automobile tour of the various electric garages of the South Side and to several department store garages, after which there was a supper and a cabaret entertainment at the Hotel La Salle. The members were entertained at luncheon the second day by the Commonwealth Edison Company. An invitation was received through R. L. Lloyd of the Philadelphia Electric Company for the association to convene at Philadelphia in 1914.

Plans comprehending the erection of a large service station in New York City are under consideration by the officials of the General Motors Truck Company, and if these are realized the intention is to erect and equip a building in a central location that will have every facility and convenience for business men who would desire to maintain fleets of machines but would not care to establish garages. The building, if the plans fructify, will be the headquarters of the business of the company in the Metropolis and suburbs.

Economy and efficiency tests will be conducted in connection with the truck show to be held at Los Angeles, Cal., the week of Nov. 17 in the exposition hall, under the management of Walter Hempel. As 70 makes of service vehicles are sold in southern California, and this will be the first show for the Pacific Coast, it is expected that the display will be very large.

The Signal Motor Truck Company of New York will manufacture a light delivery wagon and has established a factory in a building at 672-4 Commonwealth avenue, Detroit, Mich., which has been leased for five years.

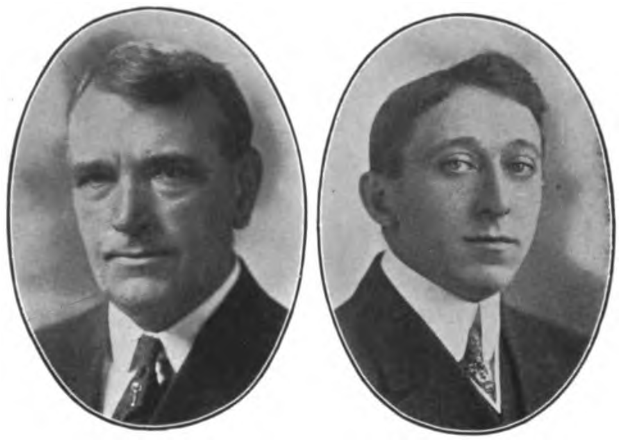
The annual convention of the sales organization of the Firestone Tire & Rubber Company was held at Akron, O., Oct. 7-10 inclusive and was attended by more than 200 branch managers, salesmen and representatives.

MAKE KELLY TRUCKS.

Two Men Who Have Succeeded Well in the Country of Their Adoption.

Two men who are largely responsible for the success of the Kelly-Springfield Motor Truck Company, Springfield, O., maker of Kelly trucks, are President James L. Geddes and Chief Engineer Charles Balough. The former was born on a farm near Banffshire, Scotland, March 16, 1857, and the latter in Nagy-Lak, Hungary, in 1883.

Mr. Geddes secured his education in the schools of Aberdeen, and came to this country in 1874. Later he became connected with the Grand Trunk railroad, and when he left that concern in 1899 he was auditor of the car department for the entire Grand Trunk system, with headquarters in Montreal. He next became general manager of the Detroit City Gas Company, with title of auditor, and later was its treasurer. This company is controlled by the Emerson McMillan Company, 40 Wall street, New York City, which has varied



At Left, President James L. Geddes; at Right, Chief Engineer Charles Balough, Kelly-Springfield Motor Truck Company.

interests throughout the country, and Mr. Geddes represented it in several capacities. He became president of the Kelly-Springfield company in April.

Mr. Balough was educated in Budapest, and in 1902 was graduated from the Royal St. Joseph University with the degree of mechanical engineer. He came to America in 1903, since which time he has been connected with the engineering department of the following concerns: Northern Motor Car Company, Great Lake Engineering Works, Ford Motor Company, Cadillac Motor Car Company and General Motors Company. He was appointed chief engineer of the Kelly-Springfield company in July, 1910.

Robert N. Barker has assumed charge of the advertising department of the Palmer-Moore Company, Syracuse, N. Y., having resigned a similar position with the Chase Motor Truck Company of Syracuse after a service of two years. Mr. Barker was formerly identified with several advertising agencies in New York City.

THE G. V. 1000-POUND WORM DRIVEN WAGON.

THE General Vehicle Company, Long Island City, N. Y., maker of the well known General Vehicle electric wagons and trucks, has just placed in the market a 1000-pound worm driven wagon that is a distinct creation in that it differs broadly from anything this company has yet turned out, but it conforms to the general appearance of motor wagons. The machine is lower and longer than any previous type built by this company, and instead of the battery being carried in a cradle under the body it is installed forward of the dash and is protected by a long sloping hood. The driver's seat is behind the dash, and this increases the length of the vehicle considerably as compared with machines with underslung batteries.

This design will be built in the 1000-pound size only, and it is intended that it will meet the favor of those who approve the vehicle that in a general way suggests and resembles the pleasure type of machine rather than that which more closely resembles the wagon. This appearance is considered desirable for light store delivery equipment, and while it is less economical of space in street and garage, the somewhat lower load centre of gravity is offset by the installation of the battery on the chassis instead of under it. The wagon has the same loading space, 72 inches length, 41 inches width and 60 inches height, of the other 1000-pound type, which has been found sufficient for all ordinary merchandise.

The New 1000-Pound General Vehicle Wagon—A Worm Driven Chassis with a Standard Panel Body.

The wheelbase has been lengthened to 108 inches, an increase of 1.5 inches, but the frame is narrower, this increasing the swing of the forward wheels and minimizing the turning radius. The tread is 58 inches. The approximate length of the wagon is 168 inches and the extreme width 65 inches, the body platform being 30 inches above the ground. The frame is a pressed steel channel four inches width, and this is carried on semi-elliptic springs, 46 inches length forward and 54 inches length rear. The front axle is a drop forged I section and the rear axle is a full floating construction. The steering gear is a semi-irreversible type with raked steering column and a large hand wheel. The tiebar, drag link and tail lever are all of ample proportion. The service brake is operated within and the emergency brake is operated without steel drums 15 inches diameter and with faces 2.5 inches width bolted to the rear wheels. The brake shoes and bands are faced with anti-friction material, not affected by water, oil or heat. The service and emergency brakes are controlled by pedals.

The wagon is driven by a single General Electric series wound motor, and the power is transmitted by a shaft with a universal joint at either end to the worm shaft and worm wheel mounted in the steel rear axle housing. The worm shaft is steel and the gear wheel, with which is assembled the differential, is of bronze, so that there is practically no possibility of noise. The differential assembly and the wheels are mounted on Timken roller bearings. The construction is with special reference to endurance, and there should be little wear even with extreme mileage. The battery and motor will give 45 to 65 miles on a single charge at a speed of 12 miles an hour, and at 15 miles an hour a mileage of 40 to 50 miles, this meaning driving on hard, level roads and loaded to its rated capacity for half the distance, or carrying half capacity the full distance.

Great care has been taken to protect the wiring, and even the bell and lamp circuits are enclosed in rigid metal conduits. The controller is a continuous torque type, affording four forward speeds and two in reverse, and this is installed beneath the seat in a metal box. The three-way type running switch is under the driver's seat in a sheet metal box, and the handle of the controller can only be removed when it is in a neutral position. The machine is unusually well protected, the application of either brake cutting off the power in the event the controller handle has not been turned, and the emergency brake cannot be locked save when the running switch is in the neutral or charging positions, and it cannot be released until the switch has been turned to the "running" position. The running switch can only be turned to the running position when the controller is in neutral. The controller "throw-off" in an emergency allows the driver the use of both hands on the steering wheel and both feet on the brake pedals. The "emergency brake lock"

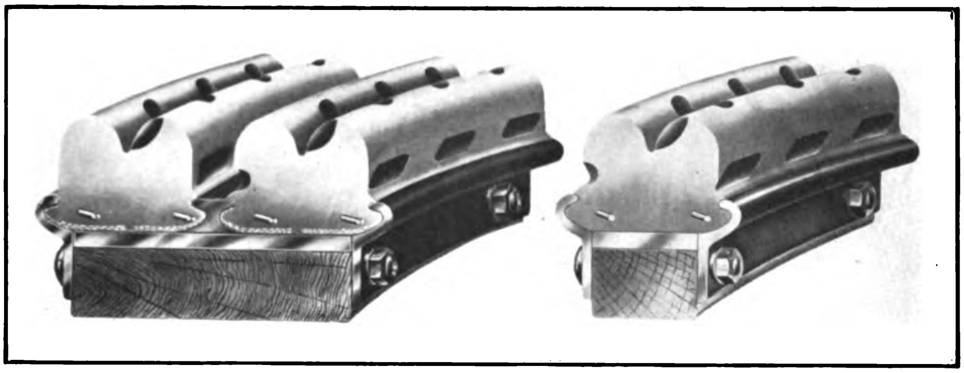
necessitates the driver turning the running switch when leaving the wagon standing, and the removal of the switch handle prevents the wagon being removed. The brake cannot be released until the switch handle is replaced and turned. Accidental starting is prevented by the running switch lock, such as might happen if the controller had been tampered with during the absence of the driver and he threw on the running switch without noting the position of the controller.

The chassis has been supplied with every convenience for economizing labor and the wheels are fitted with demountable rims. The tires are 36 by three inches. The chassis is sold with the hood, mudguards, running boards, bell, hub odometer, tail and dash lamps, kit of tools, and charging plug with 12 feet of cable. This machine was shown for the first time at the recent Electrical and Motor Vehicle Show at Grand Central Palace.

NEW MOTZ TIRE FOR TRUCKS.

Service Wagon Equipment Developed from Pleasure Vehicle Experience.

The Motz Tire & Rubber Company, Akron, O., which has for a number of years specialized a solid rubber tire in which cells afforded greater resiliency, and which was designed for pleasure vehicles exclusively, has begun the production of shoes which are intended for service wagon equipment. The Motz tire has been claimed by the maker to be built from a compound that has unusual endurance and is maintained to be resilient in a degree peculiar to itself, the combination of material and design affording a shoe that has been found to be especially efficient, particularly with electric machines, where current economy is an extremely important factor.



The New Motz Wagon and Truck Tire: A, the Dual Equipment for Rear Wheels; B, the Single Shoe for Front Wheels or Light Wagons.

The company had demand for equipment that could be used on service vehicles, and experiment was begun to develop tire design that would endure the hard work and at the same time have the qualities that had been characteristic of the pleasure car equipment. The experimentation has resulted in the production of shoes that are claimed to have all the resiliency and endurance that are realized from the original design, and to have as well all the practical qualifications that are desired for wagon and truck service. These statements are based on use for several years on machines in actual service.

The tires are made single for forward wheels and light vehicles, and duel for rear wheels and heavy machines. The slanting or diagonal cellular side construction insures high elasticity, while about the inner side of the tread are vertical cells that effectually resist skidding. The claim is made that these cells will endure and will be effective during the entire life of the tire, which is guaranteed for 10,000 miles in one year, this guarantee covering defective material or faulty workmanship, provided the vehicle is used in accordance with conditions based on the capacity of the machine.

The tire has double the tractive area of the ordinary solid tire of the same rated size. This is regarded as an important factor, involving a great saving in fuel consumption, and consequent economy of operation. That is, the tractive effort of the machine is always productive.

ELECTRIC VEHICLE HANDBOOK.

The "Electric Vehicle Handbook" is the title of a volume published by H. C. Cushing, Jr., and written by Mr. Cushing and Frank W. Smith, vice president of the Electric Vehicle Association of America, which has just been issued. Mr. Cushing is publisher of a well known electrical magazine and Mr. Smith is vice president of the United Electric Light & Power Company of New York City. The book is of convenient pocket size and has 354 pages of text, and has a flexible cloth binding. The book is intended to be a source of information on the fundamentals of the operation, care and maintenance of electric vehicles, the batteries, motors, controllers and accessories, and following a preliminary article on electric vehicle development by William P. Kennedy the chapters deal with lead storage batteries, the care of lead storage batteries, commercial types of lead storage batteries, alkaline storage batteries, charging apparatus, charging stations, measuring instruments, wheels, motors, controllers, chassis and comparative cost data. Each subject is treated in a non-technical manner and sufficient explanation is made so that a reader may comprehend logically the detail.

The "Electric Vehicle Handbook" contains numerous tables, wiring diagrams and other data that are desirable for ready reference. The work is creditable in every way and will be found useful by all who desire this character of information.

THE FUEL QUESTION AS SEEN ABROAD.

Careful Investigation by British Engineers Develops Interesting Results with Substitutes for Gasoline—Regarded as an International Problem.

THE subject of internal combustion engine fuel has been given material attention in America for several years, more because of the increase of the cost than from any fear of shortage, but in Europe, where the price of gasoline is much more than in this country, and where taxes are often imposed, and there are rigidly enforced restrictions of its use, all manufacturers and users of motors have given both the supply and the cost a marked degree of careful consideration. It is but natural that those who have to do with the production of motors and motor vehicles should begin systematic investigation, and large amounts have been offered as prizes to stimulate research, with the purpose of developing a substitute fuel and for methods of vaporization that will afford satisfactory operation of motors that are now in service.

There are millions of motors in use that were designed for operation with a fuel that may be gasoline or what closely approximates its qualities, and it is natural that those possessing such engines should desire by perfected carburetion to continue their use with a less expensive fuel. Not only this, no manufacturer of internal combustion engines cares to turn to producing other types of motors when there is such uncertainty as to the fuels, and no positive knowledge that this is necessary. As a matter of fact the building of gasoline motors has been continued for years despite the increased cost, and the supposition is that gasoline will be used for years to come.

The Institution of Automobile Engineers, which is the British national organization of automobile engineers, designers and builders, has made a special study of fuels, and at the first meeting of the season, held Oct. 8, at the Institution of Mechanical Engineers in London, the new president of that body, J. S. Critchley, dealt with the fuel question in a broad way, and considered it from an international viewpoint rather than from that of the organization of which he is the executive. As his views were applied to the possibilities of the development of the service wagon and truck, and were based on accurate knowledge, they were especially interesting. Some pertinent extracts from his address were as follows:

The demand for motor fuel derived from petroleum, apart from the petrol required for automobiles, is increasing at a very rapid rate, with a corresponding increase in price, and the automobile engineer must seriously consider what are the future prospects of obtaining a fuel suitable for the internal combustion motor at a price which will not impede the development of the industry. The cost of petrol has steadily risen until it now commands a price which, without doubt, seriously handicaps the development of the commercial vehicle. The automobile motor is a type of engine in which economy has of necessity been sacrificed in the desire for small size and weight. For example, the indicated thermal efficiency of a first class motor engine is approximately 28 per cent., while the brake thermal efficiency is about 22 per cent., whereas in tests of gas engines a brake efficiency of 26.7 per cent is obtained with an engine of five horsepower, 28.3 per cent. with a 30 horsepower engine, and 30 per cent. with a 60 horsepower engine.

Petrol is today about the most expensive fuel that can be employed commercially for power production. Taking its cost at 20 pence per gallon, approximately 7000 B.Th.U. will be obtained for one penny, and allowing for the loss in motor efficiency and the transmission losses, only about 1500 B.Th.U. for one penny remain, while crude oil at 3½d per gallon would give some 40,000 B.Th.U. for the penny, coal at 18s. per ton would give about 62,000, and coal gas at 2s. 6d. per 1000 cubic feet some 23,000 B.Th.U. With petrol at its present prevailing price it is obvious that the automobile cannot be compared in economy with other types of motors in which a cheaper fuel is employed.

In view of the enormous increase in the demand for petroleum spirit and petroleum products generally, and the consequent rise in ocean freights, there does not appear to be any prospect of a reduction in the price of fuel unless a new source of supply can be obtained.

Production and Demand in America.

The seriousness of the matter is emphasized by a short review of the situation in the United States, which clearly demonstrates that the self-propelled vehicle can no longer depend entirely upon the grade of motor fuel which it is now using, and that there will have to be a considerable increase in the specific gravity of the fuel employed in that country, where the advent of the self-propelled vehicle has changed the whole aspect of the oil industry.

The price of petrol on the west coast of America is now 15 pence per gallon.

In the United States it is computed that there are about 1,000,000 cars registered, or approximately one car to every 100 inhabitants. If the proportion were as large in this country the price of fuel would surely rise to still higher prices.

Professor Magruder of Ohio State University calculates that in addition to the motor car engines there are 1,000,000 motors used for farm work and motor boats, and that taking the average horsepower of car motors at 25 and that of other motors at 10, 35,000,000 horsepower of gasoline engines are available for the practical generation of power. He assumes that each motor uses a maximum at rated load of .75 pound, or one pint, of gasoline per horsepower per hour, and that the total requirements of gasoline would be approximately 4,500,000 gallons per hour. The total annual supply of gasoline in America is estimated at 1,500,000,000 gallons, which would last only 333 hours. If, therefore, every gasoline motor were run at its rated load each day the annual distillation of gasoline would only permit them to be operated for about one hour per day or 333 hours per year. In other words, the present supply of gasoline is sufficient to operate continuously at their rated load only five per cent. of the gasoline engines now sold and in operation.

Fuel Consumption in Great Britain.

In Great Britain the estimated amount of petrol which will be consumed during the current year is 100,000,000 gallons. The total registration of vehicles in Great Britain in 1912 was 188,874, showing an increase of 28,982 over the preceding year. A considerable number of registrations are cancelled, but I think it would be safe to assume that 110,000 motor vehicles are in use. The 'buses and taxicabs of London number about 10,000 vehicles, and will consume approximately 20,000,000 gallons, while motor boats, motorcycles and other users will absorb at least another 10,000,000 gallons, so that for 100,000 vehicles we have some 70,000,000 gallons of petrol consumed.

Assuming that the average horsepower of each vehicle is 20, and that the petrol consumed is .75 pint per horsepower per hour, the 70,000,000 gallons spread over the resultant horsepower hours would only provide for the running of the vehicles 373 hours per year, which is little over one hour per day for every day in the year.

When it is considered that commercial vehicles must run at least three times as many hours as pleasure cars, it will be realized how great the increase in the demand for motor fuel must be with the increasing output and more general use of commercial vehicles.

In face of the increasing number of cars being put into service in the United States, and the enormous requirements for fuel in that country, it is more than evident that we can rely only on short supplies from that source. In the States new methods of distilling are being brought into operation, and natural gas is being liquified in order to increase the supply, 1000 cubic feet of gas giving two to three gallons of petrol.

Low Operating Cost Needed.

Progress in the use of commercial vehicles can only be brought about by low operating cost. For many trades even the wholesale price of 12d per gallon is a serious objection to the use of petrol. At one time the stumbling block in the way of the commercial vehicle was the high cost of rubber tires. Today any compensation obtained by the reduced cost of tires is wiped out by the increased cost of fuel. In the London cab trade, where a maximum fare of 8d per mile only can be charged, the increased price of petrol entirely wipes out any small profit which was made when petrol was at 7½d per gallon.

The rise in the price of petrol which came into force in January of this year, represents £19 per cab per annum extra working cost assuming that each cab consumes 1000 gallons of fuel per annum. With London's fleet of 7000 cabs the whole extra burden over last year is no less than £133,000, which represents five per cent. on a capital of £2,660,000. If the London General Omnibus Company were subjected to the same rise on a consumption of 12,000,000 gallons the increased cost would be £225,000 per annum. Even with the lowest priced petrol at 12d per gallon when taken in large quantities, the cost of fuel for commercial vehicles is at least 15 per cent. of the total charges.

Consider for a moment what one penny per gallon means to a company such as the London General Omnibus Company, whose consumption exceeds 12,000,000 gallons per annum. It represents a sum of at least £50,000 per year. While a private owner may be prepared to pay the high prices (and it must not be forgotten that the cost of distribution is about 4½d per gallon), the increased cost of petrol is a comparatively small item in the yearly motoring expenses. In the case of commercial vehicles the fuel item may be one which makes the use of motors unprofitable, and in view of the fact that the commercial vehicle has in various applications proved its economy and utility, cheaper fuel must and will be obtained.

Heavy Oil Motors.

The demand for crude oil fuel also is increasing with the demand for petrol, and this fact may be the means of large extensions in oil fields which will help to maintain the supply of petrol, for the reason that other grades of the production can be sold at a profit. The employment of crude oil for motors, ships, etc., where economy is the first consideration, is to a large extent regulated by the price of coal. If the cost of working oil engines advances beyond the figure comparable with that of steam driven engines, internal combustion engines will not be utilized.

A few years ago it was not thought possible to construct a heavy oil engine on the two-cycle principle and reversible, nor was it believed that such motors would be as economical and reliable as four-cycle irreversible engines, yet no sooner had the Diesel engine patents expired and the door been opened for experiment, than discoveries were made which at once placed the heavy oil motor in the very front rank as a prime mover for ships of large power, and provided the cost of fuel does not increase beyond a certain point such motors will supplant steam engines for that particular purpose, and also for other kinds of work.

Year by year the specific gravity of petrol and petroleum fuels has increased. The petrol of last century had a specific gravity of .680, and every car owner who had any self-respect used to carry a densimeter. Gradually, owing to the increased demand, the gravity has been increased until we now often use fuel of a gravity of .760. The densimeter is no longer necessary, as the modern carburetor accommodates itself to a very varying range of gravities. The gravity of a fuel is not so important as the boiling point, and a high gravity fuel with a comparatively low boiling point will function better than a low gravity fuel with a high boiling point.

It really does appear that it will be necessary to consider for commercial vehicles the use of kerosene, or a mixture having a still higher gravity than the fuel now employed.

Factors in Carburetion.

The carburetor for an automobile must fulfill the following conditions: The combustion must be perfect to a degree that there shall not be any offensive odor or visible exhaust; the fuel must be regulated to respond instantaneously to changes due to varying speed and load, and the combustion of the fuel must not deposit carbon or any other substance within the cylinder. In addition to its lack of volatility, kerosene has a smaller range of combustible mixtures with air than petrol, and greater viscosity, and it is much more difficult to obtain the proper physical conditions for combustion than in the case of volatile liquids and gases. It is, indeed, difficult to fulfill the requirements with kerosene carburetors as we know them today, and I do not think we are yet able to come to a conclusive opinion as to the best method of dealing with this fluid. The provision of an apparatus for kerosene which will give uniformity of temperature and complete vaporization before the mixture enters the combustion chamber is practically impossible with a motor which is subjected to such varying speeds and loads as the present day motor engine, and while heated carburetors such as the Stewart Morris, Standard, G. S., and many others which give more or less satisfactory results, I do not consider that anything approaching finality has been reached in connection with the method and means of dealing with this fluid, and now that real necessity has arisen not only in this, but every other country, for reducing fuel cost, I feel certain that improved methods will be found for bringing into use a fuel which contains, as far as its constituents are concerned, all that is necessary. One of the difficulties with the heated paraffin carburetor is to keep the temperature constant. There is, of course, one correct temperature at which a properly vaporized explosive mixture can be obtained, and this depends upon the boiling point of the fuel employed. To insure proper combustion it is necessary to maintain the temperature up to the point of firing. Condensation causes in the first place a weak mixture, while an accumulation of the condensed paraffin gives too rich a mixture. In both cases a foul exhaust is the result, in addition to a bumpy engine.

The Secor Engine.

Professor Hutton has shown that the only difference between an internal combustion engine using kerosene oil and the gas engine proper is that the oil engine requires a device whereby the liquid fuel may be pulverized so as to be introduced into the mixture in a state of such division that the liquid fuel, in a condition analogous to a mist, shall be distributed all through the mixture of oil and air so that the propagation of flame shall be instantaneous, or practically so, as it is in a mixture of air and gas. Speaking of the Secor engine, he describes it as an "American design in which the external vaporizer is discarded, and in which the liquid oil is drawn in at atmospheric pressure with the necessary air by the aspirating or charging stroke of the piston. The proportion of liquid to air is determined by a micrometric adjustment of the inlet valve controlled by the governor. The lack of precision incident to a forced oil supply and an inhaled air current is thus avoided." The Secor system employs a multiple unit governor which regulates the fuel proportions—weak mixtures for high compressions and strong mixtures for low; the quantity of fuel mixture; the internal temperature during compression by means of the addition of finely atomized water to the mixture; the ignition timing and the use of petrol for starting.

The Bellem Motor.

The Bellem engine which is being tested by several firms in France employs neither carburetor nor compressed air ignition. This engine can be started cold, and will run not only with kerosene, but also with crude oil. The characteristic feature is a complete pulverization of its fuel in a partial vacuum. The engine is provided with mechanically operated inlet and exhaust valves; the inlet valve, however, admits only pure air, and does not open until 30 degrees before the lower dead centre, closing 30 degrees later. The fuel is admitted through a separate automatic valve into the rarified atmosphere of the cylinders. Experiments have shown that if the atomizer is used in a chamber at atmospheric pressure with compressed air passing through the valve, a certain condensation takes place.

Tests of a single-cylinder engine of this type have been made in the laboratory of the Automobile Club of France with the following results:

Revs. per minute	Brake H. P.	Gallons per H. P. Hour
820.0	5.2	
813.0	5.1	0.125 fuel, kerosene
811.5	5.0	
811.7	5.0	0.258 fuel, alcohol
773.0	5.1	
760.0	4.3	0.111 fuel, crude oil

The cylinder dimensions were 100 mm bore by 150 mm stroke, the compression with petroleum fuel was 73 pounds per square inch, with alcohol, 96 pounds per square inch, and with crude oil, 80 pounds per square inch. The specific gravities of the fuels used were:

Petroleum	0.810
Alcohol	0.834
Crude oil	0.885

Southey Kerosene Carburetor.

Another notable departure in the utilization of kerosene is the Southey carburetor, which does not depend upon vaporization by heat from the exhaust. The system adopted is similar to that of a suction gas plant; the fuel is, in the first instance, combined with oxygen to a less degree than that required for complete combustion, and additional oxygen is given to the charge in its flow to the cylinders. It is claimed by the inventor that the charge is a fixed gas and that therefore there is no loss by condensation, and if necessary the charge could be carried in pipes as with coal gas. With this carburetor it is possible to start cold, the initial explosion being produced by means of a double-pole sparking plug which is only used for a short period, as when once started there is a constant flame which automatically furnishes the required heat.

In a recent test, kerosene at 6¾d per gallon was the fuel employed, and the consumption was stated to be equal to that of petrol with an efficiency of 49.8 ton-miles per gallon. This vaporization system is being employed by Commercial Cars, Ltd.

Mixing Kerosene and Petrol.

Many users of commercial vehicles are employing a mixture of kerosene and petrol in a proportion of about two of petrol to one of kerosene. This points to the fact that the present day carburetors can deal with a fuel of even greater specific gravity than the lowest grade petrol, and it would appear that certain qualities of naphtha and kerosene might be consistently used. I have recently been operating some vehicles with a fuel of a specific gravity of 0.79, and have overcome the starting difficulty by the injection of small quantities of petrol into the induction pipe. It has been proved by using the fuel I refer to that a reduction of at least 30 per cent. can be made in fuel cost.

To assist in the use of such mixtures several inventions have been put forward. For example, the Tate vaporizer relies on the initial heating of the fuel by subjecting it to the heat of a resistance coil. The supply of fuel to the heater is governed by an electromagnetic valve which is incorporated with the device and operated by a switch from the dashboard. A current of five amperes at six volts is stated to be sufficient to give the necessary heat for starting, which occupies a period of six seconds. In this time the intake manifold is supplied with sufficient vapor for the engine to be started.

Hamilton Bi-Fuel Carburetor.

The Hamilton bi-fuel carburetor provides for using a mixture of paraffin and petrol up to 60 per cent. paraffin and 40 per cent. petrol, two float chambers and two jets being provided, one for each kind of fuel. The two fuels in this ar-

rangement are mixed in a more or less vaporized state. For starting, the paraffin jet is closed, but with increased suction the air valve lifts and opens it up. The orifices of both jets can be adjusted by needle valves to give the correct proportions.

The blending of grades of hydrocarbons is not, however, a satisfactory method of dealing with the difficulty. With mixed fuels a broken distillation curve is obtained, and the low gravity fuel vaporizes before the high gravity fuel. A more satisfactory method is to continue distillation to a higher temperature and employ a fuel with a regular distillation curve, and one with which the percentage and temperature have some definite connection.

Diesel Type of Engine.

The Diesel type of engine for commercial purposes is worthy of close attention, as it can operate on heavy residual petroleum, coal tar oil, etc. With these fuels the cost of running works out at about ⅜d per horsepower per hour, or even less where coal tar oil is a local product, whereas the cost of running a petrol engine is about 1.5d per horsepower per hour with low grade petrol. Further than this, the Diesel engine loses little of its economy when throttled down. It is, however, heavy, costly to manufacture, and it has never been successfully operated at more than about 600 revolutions per minute continuously. This was with a single-cylinder engine of 116 mm bore by 160 mm stroke, in which a maximum horsepower of 7.65 horsepower was obtained at little over 800 revolutions per minute for short periods.

Dr. Diesel, in conjunction with a French firm, is engaged at the present time on experiments on a motor designed for commercial vehicles which, while working on the well known Diesel principle, will, it is expected, be comparable with existing petrol engines as regards weight and general dimensions. The weight difficulty does not appear so formidable as it did a few years ago; considering the light weight of aviation motors compared with that of vehicle motors, it is conceivable that, with the quality of material now available, the Diesel engine might be made of a weight approximating to that of the petrol engine. The greater difficulty would appear to be in the arrangement of the fuel feed, as the Diesel engine depends absolutely on having accurately measured doses of fuel fed to the injector nozzle of each cylinder ready to be blown into the cylinder by the use of compressed air at the beginning of the stroke, and during a portion of the piston travel. With a small engine running under variable load a safe and efficient device is difficult of attainment; the doses must be reduced with the load, and the amount required when running light is only about one-quarter of that at full load. A motor four-inch bore by 5.25-inch stroke would only call for a pump with a diameter of five mm and a stroke of 3.1 mm at full power; when running idle the stroke would only need to be .8 mm. With Diesel engines of larger size the pumps are made to deliver considerably more fuel than that actually required, and provision is made for returning the surplus to the suction pipe, an arrangement which would be impossible for the small fuel requirements of an automobile engine. There is evidence that in all probability existing difficulties will be overcome, especially as the high price of fuel today is an incentive to a development which would place the automobile internal combustion engine for commercial work on a really economical basis. In view of the difficulties in connection with heating devices due to the fact that kerosene is not a volatile fluid, and that the boiling point of some of its constituents is very near the cracking temperature, it would appear that the system of pulverizing is worth following up. The eminent German engineer, Dr. Carl Buchner, holds the opinion that kerosene and the heavier fuels should be treated just as they are in the Diesel engine, and we have evidence that kerosene in a finely divided state can be ignited without any heat appliances as exemplified by the Bellem system.

Cracking and Topping Plants.

The increased demand for and enhanced price of motor fuel has stimulated invention in the direction of improvements in cracking or topping plants, and almost daily some further improvement is claimed in connection with these plants. They all have the same object, namely, to break up heavy hydrocarbons of high boiling points into lighter hydrocarbons with low boiling points, and they endeavor to achieve this end by the generally familiar principles, either by distilling under high pressure or with great heat, and artificially increased heating and cracking surfaces. The high pressure plants are a revival of old patents somewhat changed and reconstructed.

Results of Recent Tests.

Some very interesting trials have been conducted by Dr. Dieterich with benzol and other fuels on an Opel car with an engine having cylinders 70 mm bore by 100 mm stroke with standard type of carburetor. The tests were made on a stretch of road 10 kilometers in length under equal conditions regarding temperature and weather. The results obtained with the different mixtures are as follows:

1. Ether—Ordinary ethyl made from alcohol and sulphuric acid, containing about 70 per cent. of carbon, eight per cent of hydrogen, and 22 per cent. of oxygen; specific gravity, 0.718 to 0.725; calories, 9000 per kilogram; price in Germany, minus the tax, 10d per kilogram. Used as fuel, unmixed, quickly stalled motor, mainly by reason of the great cooling produced by the rapid evaporation of this highly volatile liquid.

2. Petroleum-Ether—C_3H_8, C_4H_{10}, C_5H_{12} (mainly the latter, the pentane), containing 85 per cent. carbon, 15 per cent. of hydrogen; specific gravity, 0.650 to 0.680; calories, 11,000; price 7½d. Results poor, as under 1.

3. Ordinary Petrol—(Hexane, heptane and octane), carbon, 85 per cent., hydrogen, 15 per cent.; specific gravity, 0.680 to 0.720; calories, 9500 to 11,000; price 7d per kilogram. Produced a maximum speed of 50 kilometers per hour with a consumption of one liter for eight kilometers. The usual advantages over benzol and heavy petrol in the way of responsive acceleration and the greater power arising from rapid flame propagation.

4. Heavy Petrol—(Octane and higher grade paraffin), carbon, 85 per cent., hydrogen, 15 per cent.; specific gravity, 0.730 to 0.760; calories, 10,500; price 5¾d. Produced a maximum speed of 44 kilometers, and a consumption of one liter for seven kilometers. Motor sluggish and acceleration slow.

5. Benzol—C_6H_6; carbon, 92 per cent., hydrogen, eight per cent.; specific gravity, 0.8997; calories, 9500 to 10,000; price 4d. Gave nine kilometers to the liter, but a maximum speed of only 42½ kilometers. Same drawbacks as with heavy petrol.

6. Heavy Petrol and Ethyl Ether—Equal weight parts; price 8d. Results poor; very little power.

7. Same Ingredients—Proportion 1:1.5; price 9d. Results poor, showing ether to be useless for admixture, apart from price consideration.

8. Heavy Petrol and Petroleum-Ether—Equal parts; specific gravity, 0.701; calories, 10,000; price 6¾d. Gave eight kilometers to the liter, maximum speed 45 kilometers. The acceleration was better than with heavy gasoline alone.

9. Same Ingredients—Proportion 1:1.5. The results were almost as poor as with petroleum-ether alone.

10. Benzol and Petroleum-Ether—1:1.5; specific gravity, 0.705; calories, 10,750; price 6¼d. Gave eight kilometers to the liter; maximum speed 48 kilometers. Acceleration and results generally better than with benzol alone.

11. Same Ingredients—Equal parts; specific gravity, 0.725; calories, 10,500; price 5¾d. Gave eight kilometers to the liter; maximum speed 50 kilometers. Took grades on third speed which with ordinary gasoline required second speed. An important improvement upon unmixed benzol.

12. Same Ingredients—Proportion 2:1; specific gravity, 0.797; calories, 10,300; price 5d. Gave a little more than eight kilometers per liter, and a maximum speed of 54 kilometers. Took all grades with higher gears than possible with other fuels. Good acceleration and lively explosions. Better than ordinary petrol of 0.680 to 0.720 gravity.

The supplies of benzol seem to vary very considerably in quality, and in view of the position that benzol seems likely to take as a motor fuel, the present time would appear to be an opportune one for some standard of composition to be decided upon. The best volatility and the permissible amount of impurities such as sulphur should be ascertained and fixed, there should also be some limit to the amount of toluol which it is necessary to add to keep the fluid liquid at low temperatures. The worst feature in connection with benzol is, of course, its smell, but it is a fuel which must be encouraged by all possible means.

The Use of Naphthaline.

Some attention has been given to the use of naphthalene as a fuel. A trial was recently carried out in Paris with a two-cylinder Renault cab fitted with a special carburetor consisting of a melting receptacle in which the supply of melted naphthalene is maintained by the exhaust at a heat above its melting point, and from which it is conveyed to a heated float feed carburetor. The engine has in the first instance to be started on petrol in order to heat up the naphthalene. The time occupied in running on petrol before the naphthalene can be switched on is 13 minutes 37 seconds. A stop of 10 minutes can be made without any further use of petrol, while a stop of 16 minutes necessitates its use. The consumption worked out at 14.228 kilograms for 100 kilometers, at an average speed of 34.4 kilometers per hour. The price of the fuel was six francs per 100 kilograms, bringing the cost per 100 kilometers up to 0.85 francs, to which must be added the petrol for starting.

In another test conducted by the Automobile Club of France, a car when running on naphthalene showed an economy of 60 per cent. over petrol. In Germany the Gas Motoren Fabrick Deutz constructs a stationary motor specially designed for this fuel. The production of naphthalene in Great Britain is about 126,000 tons, in Germany 175,000 tons, and in France 30,000 tons. The chemical formula is $C_{10}H_8$, melting temperature 49.2 degrees C. and boiling point 218 degrees C. The combustion of naphthalene is very similar to that of benzol, and with practically the same heat value. The price of naphthalene in Great Britain is about 75s per ton, and its production is considerably greater than that of benzol, but to convert it into a practical fuel for motors is, I venture to say, more the work of the chemist than the engineer. I understand that a Belgian chemist has succeeded in reducing it into a permanent liquid by means of a solvent.

The chemical change which takes place in the combustion of benzol and naphthalene is as follows:

Benzol		Oxygen		Carbon dioxide		Water
C_6H_6	+	150	=	6 CO_2	+	3 H_2O
78 gr.	+	240 gr.	=	264 gr.	+	54 gr.
Napthalene						
$C_{10}H_8$	+	24 O	=	10 CO_2	+	4 H_2O
128 gr.	+	384 gr.	=	440 gr.	+	72 gr.

Energizing Petrol.

A good deal has been heard about energizing, or "doping", petrol by, among other substances, picric acid, which contains 48 per cent. of oxygen, but it does not readily dissolve in petrol. Ammonium nitrate, containing 60 per cent. of oxygen, is another suggested energizer, but this again is only slightly soluble in petrol and the same difficulty has to be faced with

acetylene gas. It is, of course, oxygen that is required in order to energize, and the only known means of admitting this is through the inlet pipe.

Both in France and Germany the conclusion has been arrived at that if alcohol is to be used it must be enriched or blended, and benzol has been tried for this purpose. The 'Bus Company in Paris has made extensive trials of mixtures of alcohol and benzol, in the proportions of 50 per cent., the consumption per kilometric ton being 0.09 liters. These motors were worked at a compression of about 100 pounds per square inch and ran at 900 revolutions per minute, and were fitted with an automatic regulator to prevent any increase. The most efficient speed was found to be 650 revolutions per minute. Experiments have also been conducted with a mixture of acetylene gas and alcohol. In the Barker & White system diluted alcohol is sprayed on to calcium carbide. It would appear that the addition of acetylene adds considerably to the speed of ignition of the vapor. Picric acid has also been suggested as an enricher of alcohol, but investigation in this direction has resulted in the conclusion that it is not practicable for the reason that picric acid when mixed with the water in the alcohol has a corroding effect on metals.

Alcohol as a Fuel.

In Germany, with stationary alcohol motors, efficiencies have been obtained reaching as high as 35 to 38 per cent.; such results, however, can only be obtained by very high compression, and by the addition of water to the fuel mixture in an amount proportional to the compression. An efficiency of 30 per cent., however, can be taken as representing the average which can be obtained with a well designed stationary alcohol motor. Taking the efficiency of alcohol at 30 per cent. and the efficiency of petrol at 20 per cent. it will be found that there is a gain of at least 10 per cent. in favor of petrol by volume. It would seem, therefore, that under the best conditions a gallon of alcohol would never have the same value as a gallon of petrol. Under normal compressions all records go to prove that the consumption of alcohol is at least 50 per cent. greater than that of petrol. It has yet to be proved that alcohol can be utilized at a high efficiency with a small high speed engine. All data we have as to efficiency have been obtained with slow running stationary motors.

The slow rate of flame propagation is claimed by some to be an advantage. No doubt it gives a somewhat smoother running engine, but it is undoubtedly at the expense of power. Alcohol is a fuel which can only be considered provided it can be utilized as cheaply as other fuels. It is quite evident that 90 per cent. alcohol, as we know it, is not to be compared with petrol for high speed motors. Its heat value is low, there is difficulty in starting from cold, and it requires high compression if it is to be used with economy. The petrol engine as now constructed is quite unsuitable for alcohol, and even if alcohol were available as a fuel today the price would have to be a very low one indeed to compete with other fuels. In Germany, where the question of alcohol has been thoroughly studied, it is only used for slow speed stationary engines.

Research Work Necessary.

Before the question of the suitability or otherwise of alcohol as a fuel for automobiles can be fully decided, a tremendous amount of research work is necessary. In the first place there is the question of the production of the alcohol in sufficient quantities at a price which will make its use economical. I think it is quite useless to contend that alcohol can be made at a competitive price from potatoes or beets grown in this country. According to some authorities alcohol can be manufactured in the British colonies at 4d to 6d per gallon, and from peat at even less cost. If the motorists in this country are serious in the endeavor to provide a fuel which can be produced in unlimited quantities and not subject to market fluctuations, they should get together and devise some scheme whereby sufficient money can be provided to solve or decide the question as to the possibilities of alcohol. No doubt many of our colonies themselves would contribute to such a scheme. It seems somewhat ridiculous to pass resolutions to the effect that alcohol is the only fuel which will save the situation and to take no action to carry such resolutions into practical effect. The commercial vehicle is in need of a cheap fuel, and if alcohol could be produced at the low prices stated, means would be found to employ it economically.

Suggestions have been put forward regarding the equipment of vehicles with a producer gas plant, and such a vehicle was constructed in the Glasgow district a year or two ago. The project does not appear impossible of realization with the use of anthracite or charcoal as the fuel. With the Glasgow vehicle using anthracite coal the consumption worked out at about 1.125 pounds of coal per ton-mile, or 1025 ton-miles for half a ton of fuel at 20s per ton.

The Bonecourt Flameless Combustion might well receive consideration for steam generation. Although the system of combustion has not yet to my knowledge been applied to steam road vehicles, it certainly must appeal to those who are advocates of steam vehicles for commercial use. The Bonecourt system offers a possibility of a small flameless oil fed boiler generator in conjunction with a small turbine motor. This system of combustion consists of a burner surrounded with granulated fireproof material. The gas mixture is forced in under pressure, when the fireproof mass becomes incandescent, combustion taking place within the mass. The efficiency of the burner is very great in raising steam, while the amount of air for effecting combustion does not exceed the theoretical amount by more than about one-half of one per cent.

At the present time the petrol internal combustion engine has practically no rival, but in commercial work Providence is always on the side of low prices, and if by reason of the price of petrol other systems than those with which we are now conversant turn out more economical they will surely come to the front. We engineers have no axe to grind as regards fuel, and study all propositions with an open mind.

PETTIT NOW SALES MANAGER.

The marketing of the production of the Commerce Motor Car Company, Detroit, Mich., maker of Commerce delivery wagons, is now directed by W. C. Pettit, who recently assumed the duties of sales manager of that company. Mr. Pettit was for a considerable length of time connected with the Studebaker Corporation as manager of advertising, and has been for a number of years identified with other interests of the industry. He is widely known to the trade throughout the country, is very familiar with the conditions generally, and is unusually well qualified to carry on the vigorous selling campaign that has been projected by the company. The policy of the Commerce company has been to establish distributing agencies in different sections of the country and for three years introductory work has been carried on until conditions appear to be extremely favorable for broader and more carefully systematized endeavor. This is the foundation with which Mr. Pettit begins his work with the Commerce company

W. C. Pettit, New Sales Manager of the Commerce Motor Car Company, Detroit, Mich.

The Willys-Overland Company has elected the following officers at the annual election held at Toledo, O.: President, John N. Willys; first vice president, Isaac Kinsey; second vice president, Carlos Jameson; secretary, Royal B. Scott; treasurer, Walter Stewart; comptroller, A. H. Smith. The officers and Rathbun Fuller compose the board of directors.

The National Motor Truck & Manufacturing Company, which was recently organized to do business at Gibsonville, O., under the management of Frank Lamb, formerly of the Gramm Motor Truck Company, has discontinued its business.

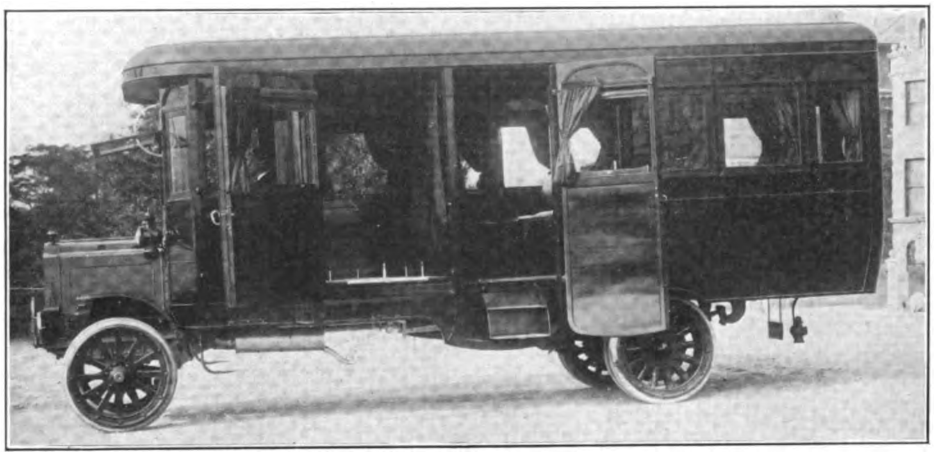
The Perfex Company, that is to build a light delivery wagon, has established itself in a new factory at Santa Fe and 52nd streets, Los Angeles, Cal., and is to begin production immediately. The machines will have capacity of 1000 pounds or less.

FUNERAL CARS FOR RENTAL.

Motor Coach Company Specializing Equipment for New York Mortuary Service.

The building of special funeral cars that will convey a casket, a clergyman and 20 persons beside an undertaker, and will replace a hearse and five or six carriages, has been begun by the Motor Coach Company, Inc., of New York City, the intention being to rent these vehicles to funeral directors or to supply them as required at charges depending upon the service. There are many cemeteries in New York, but generally in the suburbs, and the time required to go from residences to the burial places, and the difficulty of moving a funeral train through streets crowded with traffic, prompted the building of vehicles that would carry such a number as might ordinarily accompany a body to its last resting place.

The company is now producing these vehicles and the expectation is that they will be built in such numbers as will meet demands, for assumedly the advantages are numerous and the cost of the service can be no greater than with the animal vehicles that have been customarily used. The company has selected three-ton truck chassis, that illustrated being a Packard, and on these installs bodies that are built with four divisions. The forward section is intended to carry the driver, the clergyman and the funeral director. Back of this is a compartment for the casket, above the space being a wide shelf for the floral remembrances. The third section is for the friends, and the fourth for the family, they having such seclusion as would appear desirable.



Funeral Car and Emergency Chapel Built to Special Designs by the Motor Coach Company, New York City, for Rental Purposes.

The first three sections are all accessible by side doors from the walk, there being steps for the first and third doors, and the interior of the body is fitted with every adjunct for comfort and convenience. An electric fan cools the passenger space in heated weather and in winter the passengers are warmed by air heated by the exhaust pipe. The lighting is by electric dome lights, and the equipment includes a water cooler, fans, mirrors, hat and coat racks, flower vases, and there is ample provision for ventilation. In the event of storm, services can be held in the passenger section.

The bodies are handsome examples of coach building, being finished in Brewster green with black striping and silver trimming, and the interiors are finished in mahogany with black or dark green curtains and draperies, dark carpet and black leather upholstery.

STUDY TRAFFIC PROBLEMS.

Motor Truck Club Makes Comparisons of Conditions Locally and Elsewhere.

The Motor Truck Club of New York City, at its October meeting discussed at length the "Influence of the Motor Truck on the Traffic Problems of a Great City", the principal speakers being Dr. E. E. Pratt, manager of the industrial department of the Merchants' Association of New York, and Frederick Van Zandt Lane, secretary of the Property Interests Association of Jersey City. Both were of the opinion that there was a large measure of highway economy obtaining through the use of motor vehicles, a factor of immense importance in traffic and where the streets are congested, but because of the rapidity of evolution in transportation resultant from their use it has been or will be necessary to make changes in the use of the thoroughfares so that the greatest efficiency of the machines may be realized.

Both speakers were in accord in the belief that what was really necessary was careful study of the entire subject of highway transportation, both by municipal and state commissions, provided that any commission is not legislative, that would form conclusions from economic and scientific viewpoints and make recommendations that would bring about satisfactory results. The traffic congestion was regarded as being greater in New York than anywhere else in America, and whatever should be done by a commission should be upon a basis of fact and not theory. The congestion is dangerous from the viewpoint of safety and enormously costly from the viewpoint of economy, which cannot be solved by the use of the motor vehicle unless it is used with a view of conserving both.

A company has been organized at Baltimore, Md., for the purpose of affording a motor omnibus service in that city. The company proposes to use machines with two decks, having a passenger capacity of 38.

A branch is to be opened at Boston, Mass., by the Gibney Tire & Rubber Company of Philadelphia, Penn., which now has a branch in New York City

VOL. IV. PAWTUCKET, R. I., DECEMBER, 1913 No. 12

FEDERAL REPORT THREATENS INDUSTRY.

Director of Office of Public Roads, in Report of Investigation of Rhode Island's Highway System and Road Board, Recommends Raising Funds for Highway Maintenance by Increasing the Fee for Motor Truck Registration.

A REPORT submitted to Governor Pothier of Rhode Island by Logan Waller Page, head of the office of public roads of the United States Department of Agriculture, which makes recommendation that the state specially tax motor trucks to provide funds for the maintenance of the state highway system, discloses a policy that can as reasonably be applied to every state of the nation, and is unmistakably threatening to not only the motor truck and wagon industry, but will materially affect every person owning such vehicles. This report is of record and it is based on an investigation made into the administration of the state board of public roads. Just what prompted this inquiry is not stated. The entire highway system of the state was inspected, the records examined and the report was written by T. Warren Allen, a senior engineer attached to the office of public roads, and from data submitted by J. T. Veshell, engineer, and C. S. Reeve, chemist, both employed by the same bureau.

The specific recommendation is one of six, and it is as follows:

Highway at Rumford Station, East Providence, R. I., Showing Unimproved Road in Foreground, Constructed in 1912—Typical Illustration of Relative Conditions of Good and Bad Thoroughfares.

"Fifth, amend the automobile law, raising the rates for automobile trucks, and specify that the funds derived be applied to road maintenance solely, except for such an amount as is necessary to pay the expenses of conducting the automobile division of the department".

This report, being made by an employee of the office of public roads, undoubtedly, with the approval of the director of the office, is of great significance. It is a recommendation that the state specially tax motor trucks for the maintenance of highways, and these machines are now taxed by the state as personal property at the rate of $16.50 for each $1000 valuation, and were the tax for road purposes imposed this would without question, mean double taxation, which is beyond doubt unconstitutional.

The fact is patent that if the national government, through its officials, can supervise, direct or shape legislation in Rhode Island, it can do the same in every other state, and with the Rhode Island investigation as a precedent there is apparently every reason to believe that this policy will be continued unless the mo-

State Road in South Kingstown, R. I., an Illustration of the Character of Country in Which Much of the Improvement Is Made.

tor vehicle industry and those using power wagons and trucks, and every business interest that is concerned, will unite in an endeavor to determine the constitutionality of double taxation.

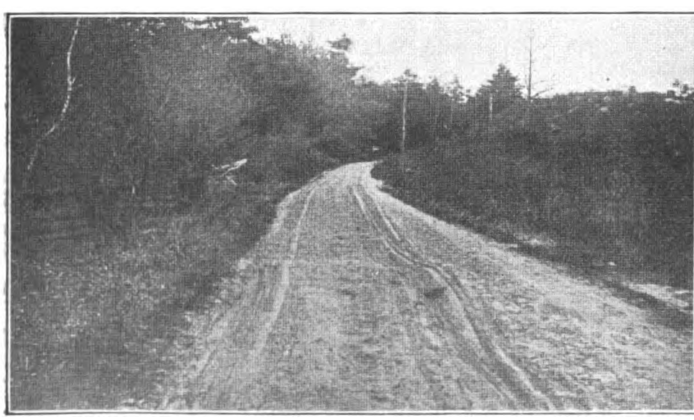
Federal Policy Far Reaching.

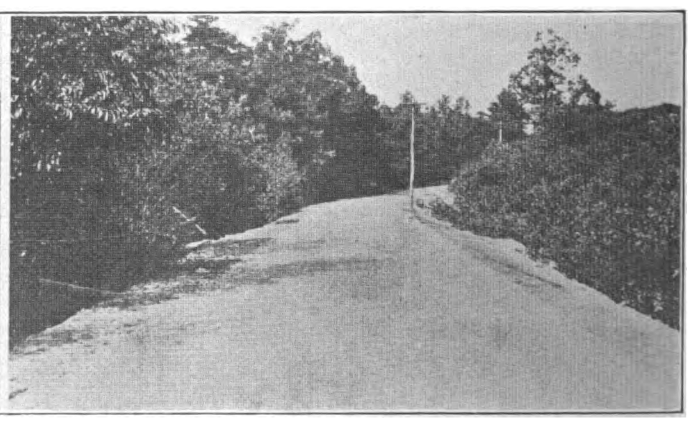
The results of this report are so far reaching and so apparent that one does not need to go into the details or to analyze facts. The official report of the office of public roads, submitted by the director, has made the recommendation stated and this can be accepted without qualifications. First, the proposal is made to amend the present state law for the purpose of increasing the fee for registration, so that it shall specify that the revenue shall be applied to road maintenance, save the amount that is necessary to pay the expense of conducting the automobile division of the department.

Analyzing this, it will be seen that every fundamental for a tax for the purpose of raising money to defray highway maintenance is proposed, that how this money shall be applied is to be provided, and that it is intended that the revenue shall be more than the cost of maintaining the division that has control of automobile registration. This means, if it means anything at all, a special tax on motor trucks to raise money, and for a specific purpose.

Motor vehicle registration is exacted under the "police power" of a state, which is a very indefinite and uncertain authority, and which has been or can be exercised to whatever extent the people are willing to tolerate. Originally the fees were based on the assumption that a sufficient revenue should be derived to maintain the office, or to pay the expenses of registration. Registration is primarily required to insure identification of machines and insure protection of persons and property. The proportion of the fee does not in the slightest add to the safety of the public. Automobile registration fees have, however, been increased by legislators for the avowed purpose of obtaining revenue, generally because of the indifference of the motorists themselves.

Automobile registration statutes vary materially. In no two states are the laws identical, and the fees are payable to state boards, state officers, commissions, court clerks, county clerks, and in some instances to town and city officials. These fees are applied to different purposes, but with rare exceptions there is always an excess of revenue over the expenditures for administrating the office of the official of jurisdiction. Owners of pleasure cars in many instances have expressed willingness to pay a tax, believing that good roads contribute to their pleasure and lessen operating expenses, and the majority are not unwill-





Typical Rhode Island State Highway: Section of Road in West Greenwich, a Sparsely Inhabited Town, but an Alternative Route to Westerly, Before and After Improvement in 1908.

for any class of motor wagon or truck, and this was fixed on the ground that, being used for business purposes and being taxed as personal property, they should not be again taxed for any other purpose. This fee was determined after consideration of this important fact by the legislative committees, and the intention was that there should be no hardship imposed on any business man. Had not the attention of the legislators been specifically directed to the importance of a minimum fee on power wagons and trucks there is no doubt there would have been uniform fees exacted on the basis of horsepower rating, and the bill that was under consideration so provided, but amendment was made in committee by unanimous consent when the effect of taxing the vehicles of business men had been carefully considered.

ing to spend money for amusement and recreation with lavishness and to an extent they would unhesitatingly resist in business transactions.

There is a decided difference in attitude of owners toward a tax on pleasure and a tax on business, and yet there has been, because of the comparatively small number of power wagons and trucks, a general disposition of legislators to include them in the same classification as regards registration fees as pleasure vehicles. Because of being so few in number as compared with owners of passenger motor cars those possessing trucks and wagons have seldom succeeded in having registration fees less than those exacted for the former class of vehicles, though in some instances this has been brought about by the forethought of men who had realized the possibilities of power wagons and made convincing arguments for their exemption.

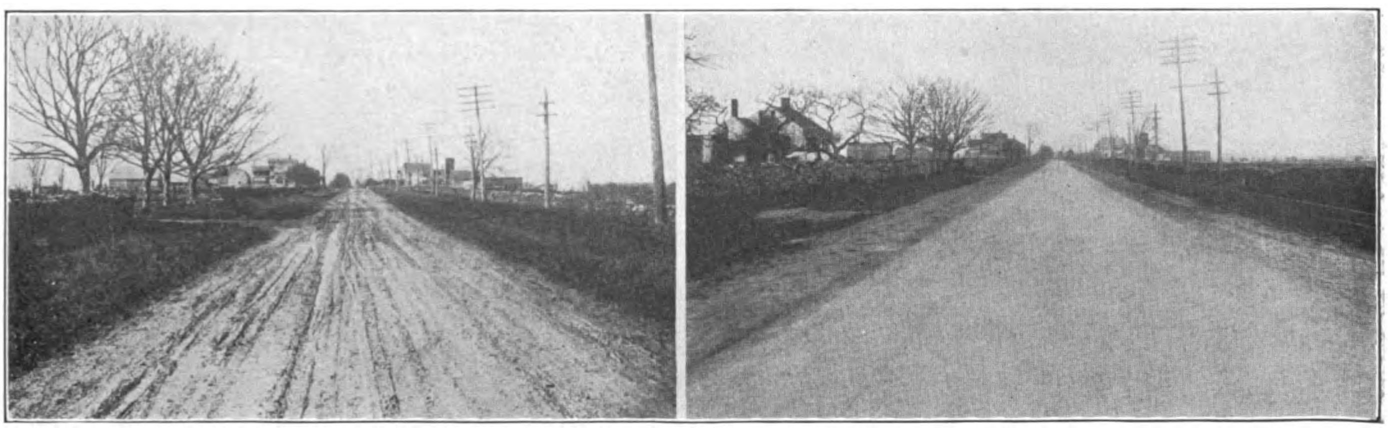
Rhode Island Fee Not a Tax.

This condition obtains at the present time in Rhode Island, where the registration fee was placed at $2

Possibilities of Trucks Realized.

No claim can be made that there was no knowledge of the probability of the increase of power wagon traffic on the highways. At that time it was believed by the committee that the use of machines would be a distinct benefit to business men, and it was understood that the real advantage obtaining would be in extending delivery from the cities that are the commercial centres of the state. Not only this, it was believed that wagons and trucks would be used solely for business purposes and that the greater part of the haulage with them would be within these cities. That is to say, that while the highways would be used by motor freight vehicles making deliveries from the cities into the towns the country residents would have equal benefit from service that was not then practical or possible, because of business competition.

The state board of public roads of Rhode Island



Stretch of Main Highway in Middletown, the Only Route North from Newport, and Greatly Travelled, Showing Conditions Before and After Improvement in 1908.

wider than standard 14-foot macadam surface built by the state was desired by a town the additional work was charged to and paid for by the town.

Water bound macadam was considered exclusively until 1906, and then attention was given to tar construction. This was experimental work, however, and the binding was generally asphalt, tar or mixtures of these materials, although several sections were built with a binder of refined tar. In 1907 a few miles of highway were constructed with bituminous material, and then the board awaited the result of usage of these roads. In 1909 real headway was made in tar construction, which was regarded as producing a superior

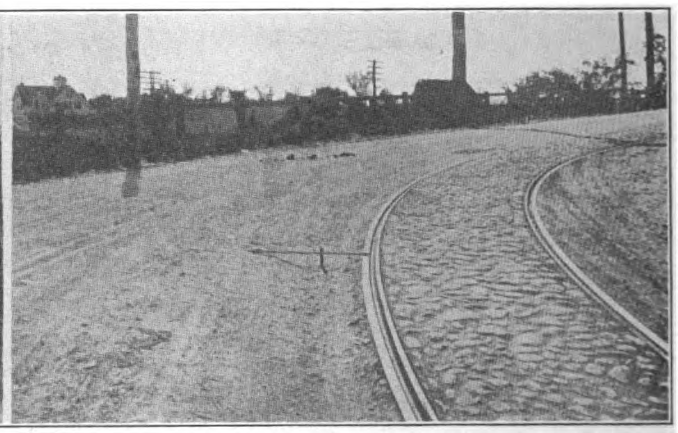
consists of five members and was created in 1902. The members were chosen by the governor, each to represent one of the five counties of the state, and they were to serve without pay. These men were prominent politically and were all Republicans. The board was authorized to construct and maintain stated main roads as state highways, some of them then existing. The state, under the provisions of the act, assumed control of these sections of improved highway and was expected to maintain them, and to construct new road to connect these sections. Appropriations were made and the work was begun, a state engineer being appointed whose duties were directed by the board. A standard road specification was adopted and contracts were made, in some instances with contractors and in others with the towns, so that the highway departments of these towns built some of the road, preference being given to the town construction when estimates were no more than contract bids. If a road

and more enduring surfacing. Since that time tar has been used to a considerable extent by the board in its work. About 26 miles of highway were built with that material up to 1912, when the construction specifications were changed so that a refined tar was required and all the contracts made specified this material, while the resurfacing in connection with maintenance was done with this binder.

One Change in 11 Years.

At the beginning of 1913, however, the board changed its policy, and because of the rejection of the proposed bond issue by the people and the lack of funds, new work, aside from the contracts previously made, was abandoned, and attention was practically given to maintenance. In November the first change was made in the personnel of the board, this being due to the death of John H. Edwards, who had served as chairman continuously from the creation of the body. His successor has been named.

Tar-Asphalt Highway in Town of North Kingstown, Built in 1909, a Fair Example of the Construction of the State System.



Water-Bound Macadam Road at Greenwood, Town of Warwick, Showing Wear at Curve, Before Rebuilding with Tar.

In the statements made that were intended to, and did, defeat the proposed issue of highway bonds, it was specifically pointed out "that there was one or two good men in the board", and the inference was made that the other members were not capable or were negligent. It was further maintained that there could be no improvement save with a change in the makeup of the board. There was at least implication that the administration of the board was extravagant, that there was lack of system and organization, and that the methods were such that good roads could not be built and kept in the condition essential for economic haulage without radical changes. The first attack was directed at the board as a means of defeating a bond issue. The charges implied practically everything that could be conjectured, and might be construed to mean political preferment, negligence, incompetence, extravagance, graft and the like. But after the defeat of the bond issue nothing further was stated until an engineer of the office of public roads of the Department of Agriculture appeared in Rhode Island and made an "inspection" of the state road system and examined the records of the office of the board of public roads.

The advent of this expert was given material publicity and he was accompanied in his tour of the state by representatives of the same newspaper that had attacked the bond issue. After he returned to Washington nothing more was heard of the subject until the report was submitted to Governor Pothier. Who brought the representative of the federal government to Rhode Island, by invitation or suggestion, what authority justified his inquiry into state methods, what reason prompted the submission of the report to Governor Pothier, and by what measure the efficiency of the board of public roads was determined, are questions that are now being agitated by the people of the state.

Motor Vehicles Pay 12.5 Per Cent. of Funds.

What interests the people is what the state has for the money raised and expended by the board. Up to the present time the board has had placed at its disposal a total of $2,965,072.48, of which amount $76,618.02 was received from towns for additional construction and $344,288.09 from the registration of motor vehicles. Of this revenue $2,417,692.98 has been expended for new construction, and $546,408.92 for maintenance, leaving unexpended $970.58. Of the total revenue of the state for highway repair and maintenance about 12.5 per cent. has been received from the registration of motor vehicles, so that the remaining 87.5 per cent. is contributed by the taxpayers. In other words, $1 of every $8 spent on road building or maintenance has been paid by owners of motor cars, wagons and trucks.

If the criticisms of the federal road engineer are well founded and correct, and the administration of the board of public roads has been all that those attacking it maintain, the fact that the automobile owners have paid a very heavy tax cannot be denied. Not only this, these vehicles have been taxed as personal property, and there is very general feeling that the valuation placed on motor vehicles has been excessive.

With the publication of the report, which was offered for publication by Governor Pothier upon its receipt, the Rhode Island Motor Truck Owners' Association, which was organized a year ago because of legislation pending that purposed to increase the registration fees on motor trucks, and which includes in its membership some of the largest industries of the state, began a campaign to oppose any attempt that shall be made at the coming session of the legislature to increase the cost of motor truck registration.

Truck Owners Act for Protection.

The association points out that if the money appropriated and raised by the people has not been expended by the board of public roads so as to obtain satisfactory results, if the roads have been poorly constructed, badly maintained, and if every implication made against the state authorities is substantiated by fact, this is not the fault of the people, nor of those who contributed to the highway fund, and to single out the owners of motor trucks as the subjects of special taxation is not only not justified, but it is against public policy and is unconstitutional. If the roads are not constructed to good engineering principles, if the materials are not enduring, if maintenance is neglected, this is because the board of public roads has been permitted to exercise its own will, and it is not responsible to the people. The board members are appointed by the governor with the advice and consent of the state senate, and if there were a complete change in the state administration it would take three years, without death or resignation, to even gain control of the board, for the members serve for five years.

The board was created with the approval of the people and it has as it is now constituted practically unlimited power. First the members served without compensation, probably because of pure patriotism, but later on all were given an annual salary. The state roads are built with a six-inch macadam surface. This construction was found to be insufficient under the heavy traffic diverted to them. Then the tar construction, which cost from $1500 to $2000 a mile, was adopted. This was an improvement, but it will not long endure under heavy mixed traffic. Heavier surfacing is imperative, and this costs money. The patchwork policy to meet political demands has been very expensive.

The federal officials appear and make report that "motor trucks should be taxed". This means a new policy, if it has the sanction of the government, and if it is applied generally, as it apparently can be, then this means that the motor vehicle industry, the owners of motor vehicles, and business men generally, will not be permitted to use this means of transportation without additional taxation. It is a serious situation, and should be given immediate attention.

MOTOR DELIVERY SHOWS 40 PER CENT. ECONOMY.

Remarkable Efficiency of Electric Wagons When Worked in Same Service with Animals in New York City, Under the Supervision of Transportation Expert.

SCIENTIFIC administration of transportation is always productive of results. This fact has been amply demonstrated, yet business enterprises seemingly well managed have failed to give attention to economies that are absolutely practical. This apparent neglect is not disregard of expense, but is generally resultant from ignorance of organization and method and the absence of accounting.

Comparison of work with different equipment is usually believed sufficient on which to base judgment, but unless based on established fact any determination is worthless. Accounting can prove the efficiency and expense of any haulage service quite as well as any other work, but unless accounts are carefully analyzed and studied the possibilities for saving cannot be realized.

Considering this subject, it is well to accept that greater efficiency is practical, and to fix a standard with a view of developing the service to at least yield these results. Records will show what has been accomplished, but unless improvement is sought progress cannot be made. With a definite purpose in view and with a knowledge of what has been done it is intensely practical to make such changes as will decrease expense or increase the work at no greater cost. This policy can be adopted with reference to horse equipment, and it can be applied to motor installations equally well. Economies can be obtained, and when the possibilities have been realized the value of administration can be definitely established.

Atlantic One-Ton Wagon with Panel Body Built for the Delivery Service of A. Silz, Inc., a New York Poultry House.

Horses vs. Motor Equipment.

When horses have been used so that the greatest practical service has been realized the question of utilizing motor equipment can only be decided by use with methods similarly adapted. That it may be necessary to make many changes and revise system and improve facilities is unquestioned, but it is also possible to work out material saving with the use of motor wagons and trucks with the same methods, and supervision.

When motorized transportation equipment has been substituted for animal vehicles the economy is assumed to be in superior speed and increased capacity of the machines, and these qualities are depended on very generally instead of reorganization and methods that will develop efficiency. By this is meant that many times the mere change from the one type of vehicle to another is expected to be productive, instead of studying the work and developing every quality that will yield results.

There are instances where men with long experience with horses have been very successful with management of motorized services, both as regards work and maintenance, but these are exceptions to the rule. Such men as have made successes usually have good knowledge of operating data and have studied the conditions of work and have adopted such methods and systems as promised to be productive. The greatest cause of failure of men familiar with horses to obtain material results from motor vehicles is inexperience with machines, which prevents working them to the greatest advantage.

Men specializing transportation efficiency are few, and their services must usually be paid for as experts, for their experience can only come with careful study of installation, the use of vehicles of all types, and the knowledge of the relative values of organization and system. They must also be capable of investigating a department, determining its faults and extravagances, learning the possibilities with continuation of the conditions of use, and after careful observation and analysis making changes that will bring about the highest efficiency and saving that is practical.

The careful expert will, if conditions justify, ask for such accounting as will establish operating expense, and from these data he will make plans for development. Such a man can establish a standard for work and endeavor to reach this productiveness. There are those who will maintain that so many variables exist that no stated value can be placed on them, but with record of what has been done experiment can be made that will determine all subjects which cannot be

worked out. Working different men and different vehicles in known conditions affords a very substantial basis for determination.

A striking example of what can be accomplished is that of A. Silz, Inc., a firm at 414-8 West 14th street, New York City, which has a transportation department in charge of Homer E. Waltermyre, an expert on haulage, and it is all the more interesting because it is what may be termed a combination equipment, there being both motor wagons and horse wagons used.

Business of Silz Firm.

The company is one of the largest of its kind in America and does a business that will closely approach $5,000,000 a year, specializing in poultry and game birds and animals. The stock is received from all sections of the United States and Canada and is brought from the railroad terminals and piers to the main storehouse. From this point it is distributed. While the firm will make shipments to any part of the country and in any quantity, its business can be said to be practically in New York City, for 85 per cent. of its deliveries are within the five-mile zone and 95 per cent. within the seven-mile zone, the remainder being sent to points beyond.

The company does not sell at retail and much of its business is with hotels, restaurants, clubs, hospitals, and the European steamship lines that have metropolitan terminals, most of the last named class being at Jersey City and Hoboken, across the North river from Manhattan. The regular delivery of the firm is made in Manhattan south of 175th street, the central part of Brooklyn, and the river front in Jersey City and Hoboken, while occasional deliveries are made to sections outside or beyond those named. In distribution horse wagons are used within a radius of three miles from the store, and beyond this motor wagons are utilized. The company maintains its delivery wagons to a high standard. The vehicles are all handsomely painted and decorated and are kept scrupulously clean and bright. The drivers are all uniformed and during the greater part of the year white duck is worn by them. The company provides the uniforms and insists that the men be always neat and their clothing unsoiled when they leave the store, so it will be seen that more than ordinary attention is given over to appearance.

Adoption of Motor Wagons.

The company has been established about 15 years, beginning in a small way, and its business has increased to its present proportions chiefly because of the quality of its stock and the satisfaction obtaining with its customers. For the first 10 years the delivery was by horse wagons, and after that time motor wagons and trucks were used to some extent, the first experience being with gasoline machines, which were followed by electric vehicles. The stable was located in a separate building directly back of the main storehouse and salesroom, this being a six-story structure, 75 by 30 feet. The location was regarded as unusually favorable because the animals had merely to be driven about the square between the store and stable, minimizing the travel incidental to the work. The gasoline cars were kept in a garage, but when the first electric wagon was purchased, this being a General Vehicle machine of 2000 pounds capacity, it was garaged in the stable.

Duties of the Expert.

Until the late spring of 1912 the delivery department of the company was directed much the same as are thousands of others, and then with a view of learning the possibilities of economy from any changes that might appear desirable, Homer E. Waltermyre was engaged to study it with a view of making observations and recommendations that might appear practical. Mr. Waltermyre, as he expresses his vocation, is a "doctor of sick delivery systems" and he had specialized in this work for several years. Until then he had worked as an expert, making investigations and developing systems and methods that could be applied to the particular subjects of his inquiry, and he

charged for this work such fees as the time required appeared to justify.

He expected to devote about three weeks to this client, but the results obtained were so practical and the economies so substantial that he was requested to continue his supervision, and has done so since that time. This means that this firm has regarded the services of an expert sufficiently productive to justify what may be considered a permanent engagement.

Equipment and Methods.

In the service at the time this work was begun were several machines, and a considerable number of horses. Changes have been made and at the present time the equipment consists of two gasoline machines, one of which is a 3.5-ton truck and the other a 2000-pound wagon, one General Vehicle 2000-pound wagon, a Champion 2000-pound wagon and three 2000-pound Atlantic wagons, the last five being electric ve-

hicles. In addition 17 horses and six wagons of 2000 pounds capacity are used. This department is worked systematically, the horses being used within a radius of three miles, the machines generally beyond a radius of three miles; no deliveries are made by horses where the haul is outside the zone they are worked in. Nine miles is regarded as a long distance delivery and few are of this length.

Observation of the delivery shows that it has been carefully systematized. The stock is generally hauled from the terminals to the storehouse by horse wagons, and it is kept in cold rooms. When wanted it is brought out to the main floor of the building, which is level with the street, and there the orders are made up. The orders are assembled in baskets and stacked in the order they are to be loaded, this work beginning each business day morning at 4. At 5 the loading is begun. The wagons are not all waiting at that hour, but they are relayed, those going the longest distances being loaded first and the others following until all are sent away. The first loads are thus made up, but after that time the vehicles are freighted as they return to the store, the work continuing until about 2, when usually the last vehicle is dispatched. After that hour the work is more with special orders, which may not be full loads, although endeavor is made to have each wagon or machine carry as much as is possible. Emergency orders are sent out as special deliveries whenever conditions require.

The sidewalk in front of the building is wide and is partly covered with a canopy, and there are wide entrances so that the men can work in loading without delays of any kind. The wagons are backed against the curb and the baskets are carried out by hand as a rule, although an experiment is being made with the use of small trucks which will each carry a stack of baskets.

As the load is made up on the floor the orders are checked and when the loading is progressing the wagon record is filled. This gives the number of the route, the date, the names of the driver and his helper, the time of arrival at the store, the time of departure, the time of return and the nature of the work, the number of baskets taken out, the name of the checker, the number of baskets returned to the store and name of the checker. Baskets are checked when sent out and received. The blank has space for 22 entries and each line gives the name of a customer, the address, the number of baskets, the time of arrival at and departure from a customer, and remarks whenever anything is necessary to report. This record is made out in duplicate and the original is taken by the driver, he entering the time of arrival at and departure from a customer, and remarks. The copy is kept in file at the office as a record and the original is also filed and preserved. These are filed in loose leaf binders.

How Records Are Made.

The record of the vehicles includes the mileage, which is taken each day from the odometers, and this is used in fixing the distance each tire is driven, as well as the consumption of fuel, oil, grease and electric current. With reference to the tires each wheel of a motor vehicle is numbered and the record of each wheel is kept, this showing the distance each tire has been driven, but in addition the name of the maker, the size, serial number, type, cost, the dates of installation, removal, repair, replacement or manner of disposition, with adjustment, are kept. With the electric wagons a record of the battery is kept, this showing the make, size, type, date of installation, repairs, date of removal, work involving any expense and other detail.

The detail record of the machine includes the make, capacity, type, cost, date of delivery, and date service began, and in connection with this is kept note of the operating expense, including repairs, maintenance, etc.

This information is supplemented with the cost of garaging, labor, attention, supplies, fuel, electric current, insurance, depreciation, interest, taxes, administration, and from the daily records a monthly statement is made up with reference to each vehicle, this showing among other data the number of the machine or wagon, the monthly and daily mileage, the average cost of operation for each mile, the total number of deliveries and the average cost of each delivery.

How Efficiency Is Measured.

A standard of efficiency is fixed and against this is placed the percentage of this standard that is represented by the work done with each machine or wagon, and the value of this statement is far greater than might be assumed, for efficiency is of record as low as 56 per cent. and as high as 94 per cent. (this with reference to motor wagons), and as high as 85 per cent. with horse wagons. This percentage is computed against each wagon or truck and as the same factors are considered it is evident that this comparison is accurate and thoroughly dependable.

When the electric machines were kept in a public garage the cost was estimated on that basis, but in addition estimate was made of the expense if they were maintained by the company, and this was found to be so much less as to justify the company in transforming a part of its stable into a garage. The expense figures realized entirely justified the expense of the investment.

The average cost a mile for operating expense is found and against this is charged the number of deliveries, the average of delivery cost being found. A delivery does not mean a stated volume of goods, for this will vary from 25 pounds to a ton, but careful observation has established that this is an entirely safe basis and is accepted as accurately representing the work. To illustrate: In March, 1913, the horse wagons were operated at a cost of 33 cents a delivery, which was very large, being due to weather and other conditions, but in April this had been materially decreased, one wagon showing 86 per cent. efficiency and a record of 24 cents a delivery.

Considering the work of horse wagons in May,

these showed a mileage cost of 31 cents and a delivery cost of 26.5 cents, which will indicate that the increase of temperature was having a material effect. During this same month one of the electric wagons was driven 910 miles, an average of 35 daily, at a cost of 20.5 cents a mile, and it made 949 deliveries at a cost of 19.5 cents each. This expense would be, according to estimate, and which figure was afterward verified by actual experience, 17.5 cents a delivery if the equipment were housed in a garage maintained by the company. Another electric vehicle of the same type was, during May, driven 1133 miles, an average of 44 miles daily, at a cost of 17.66 cents a mile, and 1083 deliveries were made at a cost of 17.5 cents a delivery. According to estimate made as before stated the expense would have been 16.75 cents a delivery if the machine had been maintained in the company's garage.

Regarding these figures from another aspect for a moment the following comparison will be especially interesting:

April, 1912.

Electric Wagon	Monthly Mileage	Daily Mileage	Operating Cost Average a Mile	Deliveries During Month	Average Cost of Delivery
1	910	35	21.125 cents	1057	18.20 cents
2	1036	40	19.500 cents	1147	17.25 cents

Efficiency of wagon No. 2, 94 per cent.

Estimate of delivery cost of wagon No. 2, if maintained in company's garage, 15.5 cents.

Horse Wagon					
	650	25	26 cents	701	24 cents

Efficiency of horse wagon, 86 per cent.

May, 1913.

Electric Wagon					
1	910	35	20.50 cents	949	19.5 cents
2	1133	44	17.66 cents	1083	17.5 cents
Horse Wagon					
	520	..	31.00 cents	615	26.5 cents

Estimate of delivery cost of wagon No. 1 if maintained in company's garage, 17.5 cents.

Estimate of delivery cost of wagon No. 2 if maintained in company's garage, 16.75 cents.

Respecting Electric Machines.

During the past year four electric wagons have been purchased and a portion of the company's stable has been transformed into a garage for their maintenance. A switchboard from which 12 machines can be charged simultaneously has been installed, and this has placed the use of the machines on the same basis as the horses; that is, they have been maintained at the fullest economy. The average cost of delivery by the animals is fixed at from 25 to 27 cents for each delivery made, and the average cost of delivery by electric machines has been fixed at 17 cents, or approximately 66 per cent. less than with horses.

It will be remembered that this is under expert administration and with the same supervision, so that it may be stated that the results obtained represent the same quality of efficiency with each type of equipment. The records are kept by the same people, and there is no doubt of the endeavor to work the wagons to their fullest capacity. The horse wagon mileage is high, which would not be possible without extra animals, there being one and a quarter horses used for each. Without reserve horses the mileage would probably shrink at least a third.

The statement relative to the efficiency of the electric machines is seemingly better than has been stated in the opinion of Mr. Waltermyre, for he is of record in stating that the delivery cost has been reduced about 40 per cent. through their use, the maintenance compared with a two-horse wagon, and that they show an efficiency of better than 90 per cent.

This is a striking example of the possibilities of motorized delivery service and of the value of high class organization and administration. The economies have been demonstrated without question, and in work where the horses would be most productive. But it should be remembered that this was accomplished by an expert. Men with similar training could no doubt do equally well with other transportation installations.

MOTOR TRACTOR TESTS AT TUNIS.

April 15-22, 1914, is the period named for the competitions for all forms of motor driven agricultural machinery, tractors, motor trucks, motors, and the like, which has been organized under the direction of the government of Tunis, Africa, and which will be open to all machines and vehicles driven by steam, electric and internal combustion engines. The announcement is made that the prizes offered will aggregate about $6000, and in addition all exhibits entered will be relieved of import duty and the government will provide free all fuel that will be needed in carrying out the tests. The general conditions are stated in a booklet entitled "Concours de Motoculture". American manufacturers who desire to enter machines in the competition are invited to send their names to the Direction Generale de l'Agricultura, 76, Boulevard Bab-Benet, Tunis, North Africa, before Dec. 31, 1913. Those entering in the competition are required to each make a payment of $10, which will be returned to the entrants when the exhibits are received at Tunis.

The Evans Motor Car Company, Nashville, Tenn., is to build a plant on the banks of the Cumberland river, near that city, for the construction of pleasure cars and service wagons. The plant will include three buildings, each 300 by 50 feet, of reinforced concrete fireproof construction, and will be equipped for the services of from 500 to 600 employees.

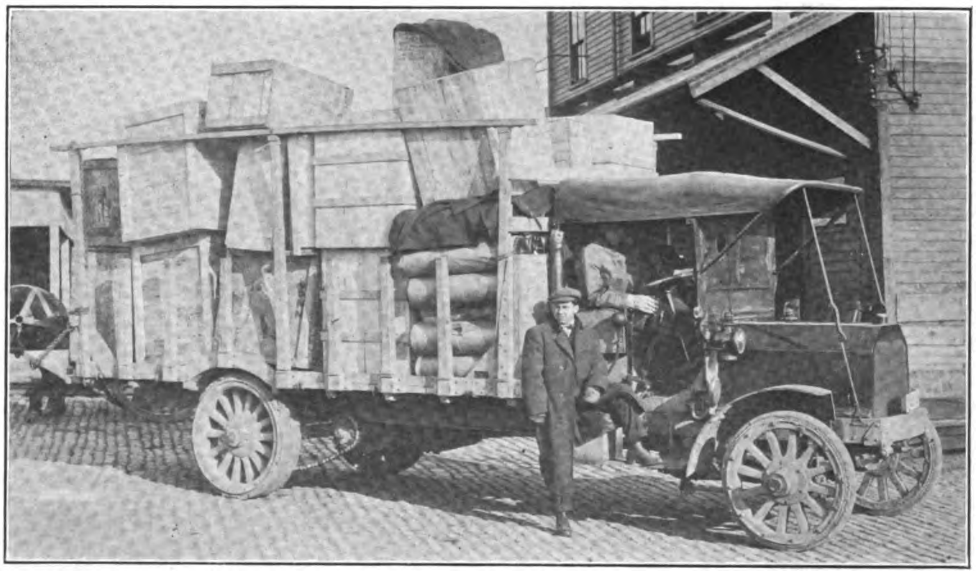
The Milwaukee Motor Company's plant, Milwaukee, Wis., which was bought at a receiver's sale by the Chicago House Wrecking Company, is to be operated beginning Jan. 1 and will afford employment at first to 100 men. The purpose of the purchasers is to develop the business and when it is profitable to dispose of it. The factory has been closed for more than six months. The price paid was $86,000.

COMPETING WITH RAILROADS WITH TRUCKS.

Mill Managers Favor Motor Service Between Plants and Shipping Terminals, Either Long or Short Hauls, for Quick and Certain Deliveries and Minimized Handling.

THE expense of transportation by railroad has constantly increased, and, even with rates regarded as extremely excessive by the shipper, the upward tendency of freight charges can be expected so long as private ownership continues, and the demands for dividends by stockholders and greater wages by organized labor continue. Where railroads compete the conditions are oppressive for industry and commerce, for transportation cost, when added to the expense of production, is just as effective a barrier to industrial and agricultural marketing as is a tariff tax, but when a monopoly exists, as in the event of a single railroad service, as is often experienced in the West and in New England, the only limit to charges is the schedule the Interstate Commerce Commission will approve.

In railroad haulage handling is a considerable item of cost, in addition to the regular transportation charges, and this expense must be added to the freight rate. The carriage from the place of production to the railroad terminal, and from the freight house to the purchaser, is usually divided between the buyer and the manufacturer, and the freightage is paid by either the one or the other. But whoever pays, those charges are in turn included in the selling price, and the public eventually settles for every transportation charge.



Providence & Woonsocket Express Company's Three-Ton Peerless Truck Arriving at Dock of the Merchants' & Miners' Line, Providence, with a Typical Load of Freight from Woonsocket Mills.

It is evident that no matter the distance of shipment there will be comparatively little change in the cost of handling, that is, in the highway haulage expense, but it will be a greater proportion of the total with the decrease of distance. The railroads haul loaded cars between stated points and receive and deliver freight at regular terminals. No matter how fast the trains are operated, the shipping is made at regular intervals, and with passenger service given precedence the freights are generally delayed. Not only this, those shipping and receiving the goods must maintain highway transportation equipment, or pay for haulage.

Gives Better Service Than Railroad.

Summarized we find that there are numerous factors for high cost, delay, the use of expensive service, and there is every reason why there should be utilization of what will lessen expense, expedite shipment and eliminate the expense of individual transportation facilities. There is undoubtedly a limitation as to the distance that motor vehicles can be used advantageously, but what this may be is dependent upon conditions that may vary in every locality. An illustration of the possibilities is the service of the Providence & Woonsocket Express Company, which has been established a year, and which has been successful in developing business in competition with the New Haven railroad system. This company operates three Peerless trucks between Providence and Woonsocket, R. I., a distance of 16 miles between the geographical centres of the two cities, and the business has been so developed that loads are carried each way, there seldom being a trip that a machine has less than its rated capacity. As a matter of fact it may be said that practically every mile the trucks are driven they carry freight.

The company does not do what may be understood as an "express" business, that is, in collecting and delivering packages or cases to or from customers, giving regular or intermittent service. It may be regarded as the contractor for the freightage of a number of mills of considerable size—some of them being very large—between the two cities. To better understand the conditions obtaining it should be known that the New Haven road receives freight at Providence for Woonsocket, or at Woonsocket for Providence, and under ordinary circumstances undertakes to have the cars at the destination the same day as the shipments are received, up to the time limit set. But the cars must be placed in the yards and the usual records made, notifications given, and the goods placed in the freight houses if in less than carloads. If the cars are fully loaded they may be run to the sidings of the

mills, if they have spur tracks, or located where they can be reached.

Special Delivery in Fast Time.

The time required for delivery depends upon varying conditions, but four hours is considered to be the least that can be allowed, and at times this is extended to 24 to 48 hours through traffic congestion. The mills ship to different points by water from Providence, to New York, Philadelphia, Baltimore and elsewhere, and there is the railroad haul between Woonsocket and Providence, with a high rate, the delay that may be caused if delivery is not made to the piers before the sailing times, and the demands of customers to be considered. The railroad yard at Woonsocket, which is scattered in six different localities, is being consolidated at a point a mile or more from the centre of the city, and this means the haulage of goods will be increased very greatly.

Some of the Woonsocket mills use yarn that is spun at Olneyville, a suburb of Providence, and this must either be shipped by freight or hauled, and this material is used constantly. Besides this all use supplies that are sent from other points and received at Providence. This condition existed when the company first inaugurated its contract work a year ago with one Peerless motor truck. The Olneyville mills receive water shipments from New York and other ports, which are preferable because of quick service as compared with the railroads, and the haulage of these freights was first undertaken, and with this work the transportation of goods from the mills to the piers. Later on the mill managers proposed making trips over the roads to Woonsocket.

Shipment of Mill Products Hauled from Plants Near Providence Ready for Delivery at the No. 3 Freight House of the New Haven Road, a Part of the Service of the Providence & Woonsocket Express Company.

The company tried out the work and it was found that two round trips could be made, this requiring from 65 to 70 miles driving daily, and that a "tailboard delivery" could be made at the mills and piers, eliminating the need of haulage by the mills at either end. For this the rates charged could be different than paid to the railroad, because of the additional advantage of no lost time. Four months later the second machine was added, and about three months ago the third truck was bought, and all three are now worked to capacity despite the business conditions.

A typical day's work for a truck and a crew of a driver and two helpers is to go to a steamer pier and collect the freight for several Olneyville mills, hauling this from three to four miles and delivering, and then taking on a load for Woonsocket. The trip to Woonsocket is made in about 1.5 hours in average conditions and the load is delivered. Then another load is taken on and this is taken to Providence and delivered at a pier, and then a second load is taken from the Olneyville mills to Woonsocket, and another freight taken on, which is left at a Providence pier before the hour for closing of receiving. The actual time on the road between the two cities will average six hours daily, and the loading and unloading is done quickly by the crew. The collection of the loads at Woonsocket may require an hour each trip, but often less time is necessary, and unloading is frequently done in from 10 to 15 minutes.

Co-Operation by the Customers.

Thomas Sullivan is manager of the company and he believes in the economy of the time of the machines, which is secured by having men enough to handle the freights quickly, and he has the co-operation of the mills to the extent of having the goods in readiness at stated times, so that there shall be little or no delay. An operating schedule is maintained for each driver and this is carefully observed. With the use of the trucks the mill managers can depend upon receiving material or other freight practically at the times fixed, and should there be reason additional trips are made. The greatest mileage of any one day has been approximately 125, and freight was carried nearly all this distance.

The purpose is to afford the customers what may be regarded as an express service by road vehicle, delivery often being made in less than two hours between the two cities, this minimizing records, saving in time and in investment in equipment, and justifying a charge that can be larger than what would be made by the railroad, and yet decidedly economical when every consideration is weighed. The quick trips are worth more to the mills were there no other saving, and with the other factors of material importance it will be understood why the mills have preferred to have this service.

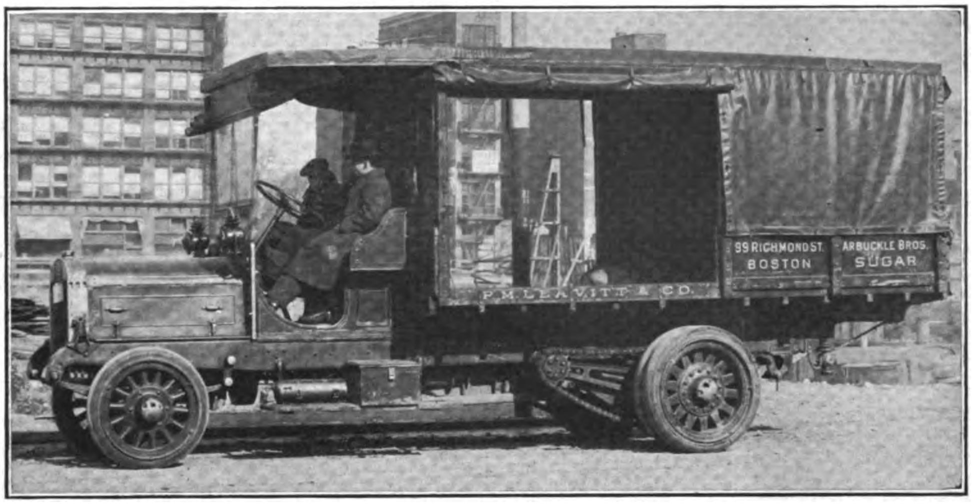
The trucks are fitted with special platform bodies with wheel housings built into the decks, with stakes and frames at the sides so that loads of large bulk can be carried safely roped. The platforms have length

of 16 feet and width of seven feet, and there is the tailboard width that can be utilized when necessary. The frames also support tarpaulin covers, so that the loads may be amply protected in the event of storm.

Trucks Carefully Operated.

Manager Sullivan is extremely careful as to the attention the machines shall receive. The trucks are inspected weekly at the Peerless service station and kept in excellent condition, while they are gone over carefully by the drivers each day. Nothing is neglected for the business is dependent upon the machines being constantly operative. After a year's experience with the company the customers have learned to rely upon it, and the coming spring a garage will be established in a building originally built for a stable, and it is probable that more trucks will be bought and the service materially increased.

The railroad company has sought to retain its business in Woonsocket, offering to ship special cars in very quick time, and making proposals for improving its service, but it has not been possible for it to go beyond the limitations of railroad facilities, and it can neither collect nor deliver goods, nor equal the time of delivery made by the trucks. The mill managers are willing to co-operate with any proposition that will benefit themselves, and they are aware that their requirements are immediately considered and, so far as possible, provided for by the management of the express company, while they have to take what the railroad is disposed to grant, no matter what the effect upon them from a business viewpoint. This is a condition that has brought about the development of successful competition with trucks with the railroad, and the example can be made the most of by others wherever railroad domination over business obtains.



Seven-Ton Vulcan Truck Used for the Delivery of Sugar by P. M. Leavitt & Co., Boston, Mass., to Suburban Customers.

The Hood Rubber Company, Watertown, Mass., maker of Hood truck and Shawmut pleasure car tires, has increased its capital from $2,500,000 to $3,500,000 by the issuance of $1,000,000 preferred stock, which is to be sold at not less than par whenever in the opinion of the directors such sale is desirable.

RECEIVERS FOR ATLANTIC VEHICLE CO.

Well Known Maker of Electric Machines Handicapped by Lack of Capital.

The directorate of the Atlantic Vehicle Company, with factory at Newark, N. J., and executive offices at 1600 Broadway, New York City, made petition through Vice President Ralph Sanger for appointment of receivers to the United States district court at Newark, N. J., which petition was granted Nov. 11, and A. Perry Osborne of New York and Harry L. Davisson of East Orange, N. J., were appointed by the court to administer the affairs of the company.

The company was organized early in 1912 with capital of $100,000, with McKinley Boyle as president, Ralph Sanger as vice president, Arthur J. Slade as chief engineer and Herbert L. Satterlee as general counsel. The vehicles built by the company were designed by Mr. Slade and have a high standard for efficiency, and because of the quality of material and the workmanship have commanded prices above the general average for machines of similar capacity. The company established a plant at Newark that is admirably equipped and has a capacity of about 200 wagons and trucks annually and it confined its sales activities to New England and the East.

The cost of the factory and the initial promotion has been large and the need of capital to meet the demands incidental to development has been keenly felt for a number of months. To continue the business on a sound basis additional investment had become necessary, and as obtaining new capital was extremely difficult because of the disturbed condition of business and finance, the officials of the company believed that the interests of the stockholders and the creditors could best be served by the appointment of receivers. This decision will insure the continuance of the business until plans for the future can be developed and allow the completion of the orders on hand.

Because several rates of taxation are provided for by the new Michigan automobile registration law, which will become effective Jan. 1, and is not uniform in its effects, an endeavor is to be made by organizations of motorists of that state to have it declared unconstitutional. A test case is now being prepared.

A show of service wagons and trucks will take place at Cincinnati, O., in Music Hall, March 2-4, and will be conducted by the Cincinnati Automobile Dealers' Association.

TRUCKS DEVELOP WHOLESALE GROCERY TRADE.

BUSINESS economy may be established from many viewpoints, and when delivery must be made promptly and patronage can be increased by quick service, even if the expense of transportation is not relatively lessened, there is no doubt of the greater profits that may be secured. This statement is made to emphasize that it is not always possible to demonstrate economy in ton-mile cost, in rates charged, or in prices paid, but volume of transactions may be the actual measure.

A case in point is that of the Woonsocket Wholesale Grocery Company, Woonsocket, R. I., which has, through the use of motor wagons, not only increased the area in which it transacts business, but has stimulated its out-of-town trade to such an extent that President Frank W. Holden says, without question, that he would not know how to do business with horses, by this meaning that he has found the machines to be of extreme value to him.

Woonsocket, with a population of about 40,000 people, is but 16 miles from Providence, the second city in population of New England, and despite this fact it is a commercial centre of material consequence. New England cities may be comparatively short distances apart and connected by railroads, trolley lines and excellent highways, but each attracts business from a surrounding territory that would, in the minds of those not familiar with the conditions which exist, seemingly be drawn to a larger city.

Two-Ton KisselKar Wagon in the Service of the Woonsocket Wholesale Grocery Company, Woonsocket, R. I.

Woonsocket draws largely from the towns located north and west for a distance of at least 15 miles, and for about 10 miles east and six miles south, there being numerous manufacturing communities that have populations ranging from a few hundred to 6000 or 7000 people, and this company has developed business of considerable proportions with store keepers. One reason is that prices can be quoted that will be at parity with those of houses more distant, the delivery can be made more quickly, and if the customer pays the freightage this is relatively less.

The company's salesmen regularly visit the villages and towns and solicit business, and usually purchases are made sufficient to meet expected custom. Occasionally special orders are given by telephone. Up to March, 1912, the company made deliveries in Woonsocket by horse wagons and all out-of-town orders were sent by freight or express. Purchasing by the customers out of the city was done with expectation of more or less delay, and sufficient time to permit delivery was necessary. This was not a hardship in one sense, but orders were occasionally sent to other concerns because there would be but little more time required, and because of the time required the company could not develop business that seemed possible. The company bought a two-ton KisselKar wagon in March, 1912, and with this planned to make delivery outside of the city, and to utilize it in short hauls when not required for the town delivery. Regular days were fixed for visiting different localities and the salesmen emphasized that within a comparatively short time, two hours or less, after receiving orders on these days, delivery could be made direct to the stores.

From the viewpoint of the company this was a saving of time in packing, for the goods could be carried without preparation as when sent by freight or express. The hauling to the freight house or express office was eliminated, and the customers had the advantage of receiving the shipments directly at the stores instead of doing their own haulage, or hiring others to do this work. Besides this, the goods were received in better condition as a rule and the unpacking was simplified. Then in the event of emergency a special order could be received in a few hours and a stock brought up to standard.

The advantage of buying where there was a distinct saving was quickly apparent to the customers and the orders began to increase. It was possible to go to points that were formerly difficult to serve because of the limited means of transportation, and to serve the stores in remote sections as well as those close at hand. In August, 1912, a ton KisselKar wagon was ordered, and since that time both machines have been used regularly. Perhaps an illustration of a single afternoon's delivery between Woonsocket and Pascoag will serve. Previous to the use of the machines if the orders sent to this route weighed a ton business was up to standard, but five tons of goods

were sent out to the customers a few days since, this requiring the machines to make three trips.

This is a fair example of the development of the out-of-town patronage, and it has constantly increased. The expectations are that by next spring another machine will be needed. The wagons are used for city haulage, and while this is practically no economy in the mind of President Holden, it is certainly not an extravagance. The cost of delivery is, Mr. Holden says, perhaps not largely reduced, but the business has been so largely developed by motor equipment that he will consider no other means of haulage. The wagons are economically kept. They are stored in Mr. Holden's private garage and they are driven by careful, experienced men. They are required to keep the machines in good condition and each man is allowed a half day a week to work on the one he drives. Fast driving and overloading is guarded against and neither wagon has been out of service because of accident or failure. Unusually good results have been obtained with tires. The two-ton machine was driven 14,000 miles before the rear tires were renewed, and the front shoes are still in use and will probably last to the end of the second year. The ton wagon was originally fitted with pneumatic tires, but about three months ago those on the rear wheels were replaced by solid shoes that have thus far given excellent satisfaction.

Ton KisselKar Wagon Used by the Woonsocket Wholesale Grocery Company, Woonsocket, R. I.

The wagons are driven largely over country roads and with good loads. The longest single delivery trip is about 35 miles, and the shortest is about 20 miles, but these are route distances and are usually covered unless a special delivery is being made. The company has a spur track at its warehouse and carload shipments are received direct, but when the receipts are smaller it is necessary to haul these from the freight yards. Both machines are worked with two men when doing route delivery, and the loading is by as many as can work conveniently at the warehouse, so that time is economized. Usually less than five hours is required to make deliveries on the 35-mile route, and considering the handling and the numerous stops what may be regarded as fast time is made.

PITTSBURG SHOW, FEB. 14-21.

Fourth Annual Event Will Include Pleasure and Commercial Cars.

The Pittsburg Auto Show Association has completed arrangements for its fourth annual show, which will be held Feb. 14 to 21 inclusive. Pleasure and commercial vehicles will be exhibited, and the display will be known as the Big Exposition Auto Show. The officers of the Pittsburg Auto Association are as follows: President, Aaron DeRoy; vice president, J. Casper; secretary, J. D. White; treasurer, E. A. Williams; board of directors, A. A. Buhl, C. C. Laughner, W. M. Laird, R. D. McCurdy and Elias Lange. J. H. Zimmerman is show manager and headquarters have been established at 130 North Highland avenue.

STUDEBAKER OFFICERS.

A. B. Erskine, who was treasurer of the Studebaker Corporation and stationed at Detroit, Mich., has been named vice president of the company and will continue the duties of both offices. James G. Heaslet has been made chief engineer and vice president in charge of engineering and production. Ernest R. Benson is now sales manager and vice president in charge of the distribution of the vehicles produced. Arthur L. Philip is made assistant sales manager, in charge of the motor car division. Charles D. Fleming is made assistant treasurer and H. E. Dalton is made general auditor, these being general promotions.

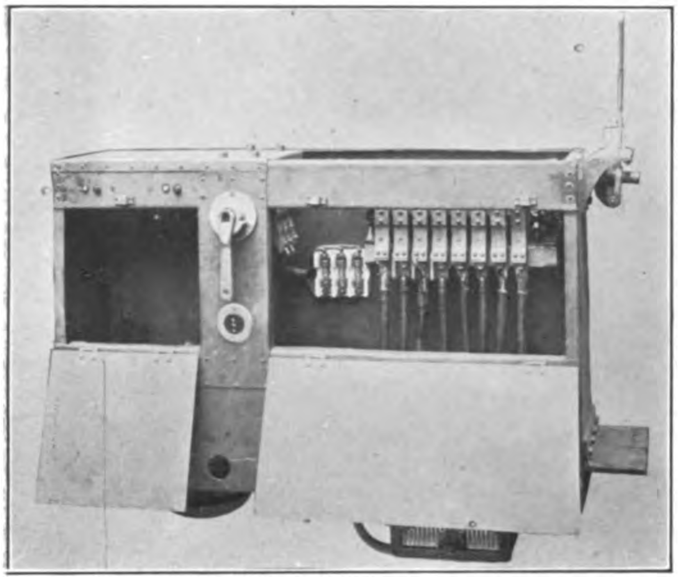
The new buildings at the plant of the Edison Storage Battery Company, Orange, N. J., are now complete and in readiness for the installation of the machinery, which is now being delivered. It is expected that by the first of the year the factories will be ready for production, and for their operation more than 2000 persons will be required.

R. M. Benn, formerly connected with Claire L. Barnes & Co., of Chicago, Detroit and Cleveland, O., has been made sales manager of the Lefever Arms Company, Syracuse, N. Y., which is engaged in the manufacture of vehicle parts.

Having outgrown its present branch at 918 Pike street, Seattle, Wash., the Firestone Tire & Rubber Company has decided to establish a branch and service station in that city and will erect a building with 20,000 square feet of floor surface to house it.

IMPROVED GENERAL VEHICLE MACHINES.

THE General Vehicle Company, Long Island City, N. Y., builder of General Vehicle wagons and trucks, has incorporated in the designs of machines



The New General Vehicle Controller Box, Showing the Lamp Circuits Beside the Controller, with the Three-Way Drum Type Running Switch, and Under This the Plug for a Portable Lamp.

that it will produce hereafter a number of refinements or improvements, these being such as will afford greater satisfaction for the owner and the operator, and they will not in any way change constructions that have been found to be practical and enduring. The General Vehicle machines were standardized in 1907 and have been continued since that time without change, and in the refinements that have been made no departure was taken from what has been proven by time and service.

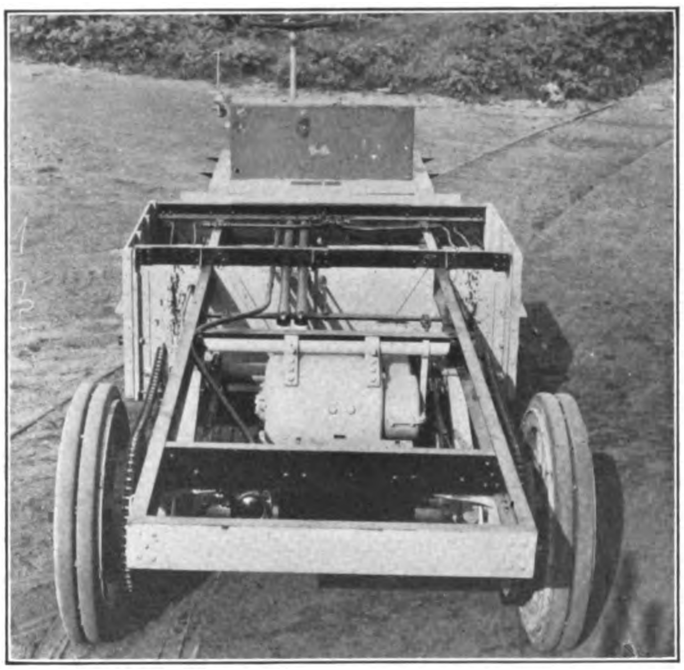
The 1000-pound worm-driven machine will be built as it was first displayed at New York, but the refinements stated will be applied to all the six sizes of machines produced, aside from the addition of a second brake, which will be installed on the two, 3.5 and five-ton trucks.

The first of these is the use of metal conduits for the protection of the power wiring, which will extend from the motors forward above the battery boxes, and to the controller boxes. In previous productions the power wiring from the batteries to the motors and forward to the controllers was carried in channels of substantial wooden stringers that were mounted on the cross frame members, and the wires were secured by porcelain clips attached to the stringers. While this construction afforded accessibility and endured satisfactorily, there was a possibility of damage to the insulation and complications arising from saturation by acid or water.

In the place of the channelled wooden stringer and the exposed wiring two metal conduits are carried from the motor to the controller box, which are secured to the cross frame members and have the support of the ends of the battery box. These carry the power wiring, so that it is protected in every way from damage, and should there be occasion any lead can be replaced in a very short time without removing the body. Installed in this manner there should be no reason why power wiring should not endure for the entire life of the machines.

The General Vehicle wagons and trucks have always been equipped with an ample brake operating in large drums on the rear wheels, actuated by a pedal. The design of the 4000, 7000 and 10,000-pound machines continues this brake for general use in operation, and a second brake of the contracting band type operating on drums mounted on the jackshaft between the sprockets and the chassis frame through a pedal, has been installed for emergency service. This second brake gives what may be regarded as absolute control under any circumstances, and eliminates the use of the controller for regulating speed when descending grades, which has been resorted to by some drivers, which, if the driver were inexperienced or careless, might result in damage of the controller, battery or motor.

The controller boxes are now constructed of sheet metal, these serving as the seat. These boxes are divided into two compartments, the larger of which contains the controller. As made, these boxes have hinged doors at the front which effectually protect against moisture and dust. In the controller com-



Refinement of General Vehicle Chassis, Including the Emergency Brake on the Jackshaft, the Rigid Metal Conduits for the Power Wiring and a Sheet Steel Tool Box Beneath the Motor.

partment are installed the terminals of the lamp circuits so that cartridge fuses may be used, instead of open fuses, these being a safeguard against fire and protect-

ing the mechanic who may have cause to replace them. The smaller compartment may be used for the storage of small articles of equipment that may be required.

Mounted on the controller box between the two doors is a three-way drum type cut-off switch that eliminates any possibility of the machine being started when it is being charged, and a mechanic can work on the controller during the charging of the battery. By removing the switch handle the driver can leave the machine "dead", so that it cannot be started during an absence, thus protecting the vehicle and insuring it against theft or accidental starting. Below this switch is a plug receptacle, by which a portable lamp may be quickly connected by the driver for work on the road or by a mechanic while in a garage, instead of using a head or tail lamp. Under the rear of the chassis frame is installed a large sheet steel tool box, which is lighted by the tail lamp, and tools can be quickly obtained whenever desired at night. In addition to this all of the spring shackle bolts are provided with ample grease cups, which, through thorough lubrication of the springs, shackles and bolts, will insure the fullest action and extreme endurance of these parts.

THE DETROIT FENDER.

The enactment of municipal ordinances requiring the equipment of service wagons with fenders that will protect the public has directed the attention of the owners and users of such vehicles to the possibilities of fender equipment. Naturally this attitude of the municipal authorities has stimulated invention, and the Detroit Fender Company has been organized at Detroit, Mich., to construct equipment that will meet the requirements of all local ordinances.

The Detroit fender is built with two sections, each formed of heavy tubing, the frames being filled with a large mesh wire grating or netting. A steel arm is attached to each spring horn, being supported by bolts through the horns and the spring eyes. At the ends the arms are formed so that they parallel the ground, and to these ends are fixed the footboard or "scoop" of the fender, which is normally carried about six inches above the roadway. The spring horns and the chassis frame serve as the mounts for the lower ends of two members that are united and form triangular brackets which support the upper half or section of the fender.

The top portion of the fender is pivoted on these brackets so that it may be lifted from the bottom and folded back against the radiator, this being lifted when the driver wishes to reach the engine crank. The forward members of the brackets support and brace the fender when the top section is dropped. The lower corners of the top half of the fender are braced with diagonals, this considerably strengthening it.

The upper ends of the arms supporting the lower section extend above the spring horns and to one of these is attached a rod that is carried back to the side of the dash at either the right or left. The rod is placed at an angle and by a direct pull on it the driver may lift the fender six inches above the normal height if necessary to clear an obstruction. The lower half of the fender can be lifted and folded against the upper part while in a garage, so that the machine can be worked in the usual space without possibility of damage. The weight of the equipment as installed is approximately 75 pounds. As the fender covers each wheel while the truck is moving directly forward, but does not extend beyond the hub caps, it will be seen that it does not interfere with traffic, yet it affords all the protection that could be required.

KNOWLEDGE MEANS ECONOMY.

President George A. Kissel of the Kissel Motor Car Company, builder of the KisselKar wagons and trucks, after making careful analysis of the prospects for the industry during an extended trip in which he visited his agents in different sections of the country, maintains that there is no question in his mind that the coming year will show the greatest strides in the history of the industry so far as the production of service machines is concerned. He comments:

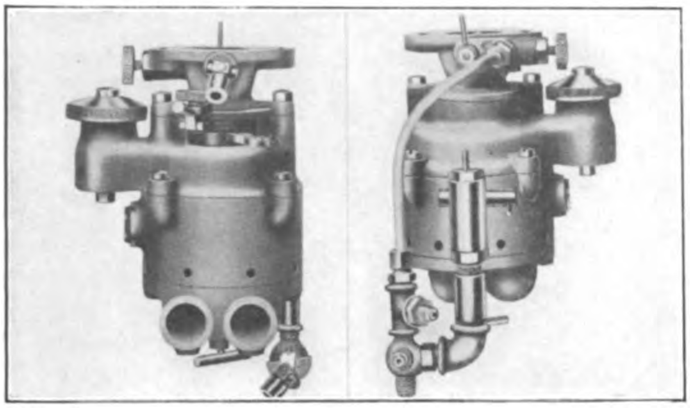
"The truck campaign is just passing out of the educational stage. Trucks have proved themselves in actual service tests covering a period of years, and business men, formerly skeptical, seem now to be thoroughly convinced that to keep up with competitors they must adopt motor delivery. In addition to this, experienced and reliable truck drivers are constantly multiplying, thus obviating a formerly bothersome problem. Gradually, also, improved loading and unloading methods are being adopted to keep trucks moving and thus up to their maximum possibilities. Trucks handled rightly are such an obvious economy over horses, in both time and money, that there is no question regarding their ultimate domination in local and interurban delivery".

The New Orleans postmaster has developed his parcel post distribution service by using trailers with the motor wagons available for this work. The requirements were such that the motor equipment was inadequate and so that there might be no diminution of the delivery animal wagons were fitted with axles built for motor vehicles, and street car drawheads for coupling them to the machines. The trailers have been found to draw easily and the loads can be largely increased, the motor wagons having sufficient power to take them wherever needed and with practically no loss of time.

William H. Stilwell, M. E., who was connected with the sales department of the J. S. Bretz Company, New York City, for a considerable period, has resigned to become sales manager and engineer for Joseph Schaeffers of Cleveland, O., who is importer and distributor of H. C. B. ball bearings, with offices in the Marion building, Cleveland.

THE KNOX MODEL E KEROSENE CARBURETOR.

FOLLOWING exhaustive experimentation covering a period of nearly three years, supplementing an engineering knowledge developed by years of prac-



The Knox Kerosene Carburetor, Showing the Construction from Either Side.

tical work, the Camden Anchor-Rockland Machine Company, Camden, Me., has perfected a carburetor designated as model E, which is designed to use with kerosene fuel in all internal combustion engines. The company has manufactured carburetors more than 12 years and half that time has experimented with kerosene carburetion, the possibilities of economies through the use of that fuel having prompted unusually careful investigation.

The company three years ago, because of the demand from its foreign trade, began the production of a carburetor designed to use either kerosene or gasoline, and in practical service this instrument gave excellent satisfaction. The increasing cost of gasoline and the comparatively smaller price of kerosene prompted further investigation with a view of utilizing the latter fuel constantly, aside from starting, and early in 1911 E. P. Lamb, the company's experimental engineer, began development of a carburetor that would be equally efficient for automobile and tractor motors and stationary and marine engines. The results obtained have been in every way gratifying, and such efficiency has been realized in continued service that the company has made plans for producing the instrument to meet any demand that can be reasonably anticipated.

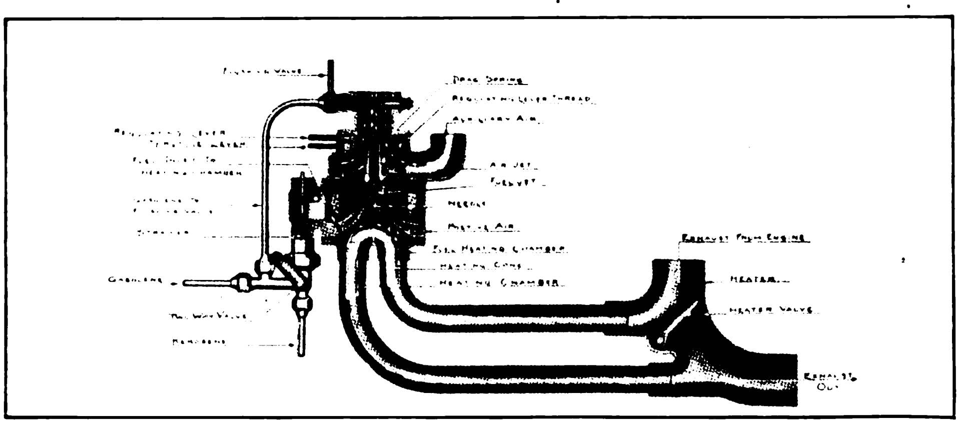
The carburetor is so designed that the engine may be started with gasoline, which insures operation in coldest temperatures, and then kerosene is used that is gassified by heating the base of the instrument from the exhaust. An explanation of the operation of the carburetor is given by the company's engineer as follows:

The fuel is admitted to the carburetor in the usual manner. In the base of the carburetor is a conical shaped heating chamber. The heat is derived from the exhaust line and the temperature is regulated by a damper or valve in the exhaust pipe that is shown in the accompanying illustration. This damper is controlled from the dash. As the chamber in which the fuel is heated is of such capacity that the fuel will flow over the cone, which is made of soft copper and has a large heating surface, no accumulation of kerosene follows and the fuel is transformed to gas as it passes the needle valve, which is maintained to be the only correct method of carburetting kerosene.

The needle valve and the nozzle are peculiar in construction. The gassified fuel passes the regulating needle into the nozzle through a series of very fine holes, and the heated constant air is supplied to the nozzle through a second series of small orifices. The nozzle is so constructed that the fuel holes intersect the constant air holes at the outlet point, a condition that insures atomization of the mixture as it enters the mixing chamber. The needle valve and the nozzle are adjustable and can be raised or lowered by the movement of the throttle lever. The auxiliary valve that controls the additional air supply serves as a throttle. No other control is necessary.

Claims of the Maker.

The qualities of the carburetor, for which special claims are made by the maker, are protected by patents, and these include the method of heating the fuel, the method of increasing the speed of the gases and the method of thoroughly atomizing the mixture. The carburetor is so constructed that either gasoline or kerosene may be used, but for convenience it is built with a flushing valve and the gasoline is not passed through the carburetor. When the motor is first started the fuel is gasoline, supplied by opening the flushing valve, this valve having a needle regulation and being controlled from the dash. After the engine has been run from 15 seconds to three minutes, depending upon conditions, the flushing valve is closed and the kerosene fuel is drawn upon without change in the regulation.



Cross Section of Knox Kerosene Carburetor, Showing the Principles of Operation and the Manner of Heating from the Exhaust.

The maker claims that a gain averaging seven per cent. is made in speed and power when using kerosene, as compared with gasoline, and with practically the same volume of fuel; that further, the standard automobile motors can be operated successfully with kerosene fuel, demonstration of this efficiency leading to extensive tests for some of the motor manufacturers; that when fitted to marine motors the model E carburetor is decidedly superior to the model D instrument, and that in ordinary conditions the marine motor can be started cold with kerosene by priming it well with gasoline. When used with gasoline as fuel the statement is made by the maker that the carburetor, because of its construction and method of vaporizing, will deliver a mixture to the motor superior to that of any other carburetor, increasing the power and decreasing the fuel consumption. The saving with kerosene as fuel instead of gasoline is the difference in price. The company is now building an addition to its plant and has ordered special machinery for the manufacture of these carburetors, and will shortly produce them in standard sizes of one, 1.25 and 1.5 inches, to supply the manufacturers and the trade.

POWER TRUCK COAL DELIVERY

Conditions Experienced by Those Distributing Fuel in New York City.

The conditions governing delivery of coal in New York City and the possibilities of utilizing motor trucks was discussed at the November meeting of the Motor Truck Club. The policy of the organization is to consider the practical experience of men engaged in highway haulage and from the facts developed to determine means of better utilizing motor vehicles, the members profiting through the broadening of their knowledge and the exchange of opinions.

An enormous volume of coal is delivered annually in New York City and its suburbs, and the possibilities for the use of motor equipment appear to be almost unlimited. A very large part of the fuel is delivered during the spring, summer and early autumn, so that for seven months of the year maximum delivery facilities are required, while the remainder of the year the demands are less, being generally to those who cannot store large supplies, in contract deliveries to factories, shops, large buildings, hotels, etc., or emergency orders from families.

Without exception, the experience has been that during the period of the year when the bulk of the coal is hauled the motor trucks have greater efficiency in the larger capacity and greater speed, but during the remainder of the year the earning power is materially lessened. When horses have been used the dealers have rented teams, carts and drivers or engaged in work for others, there being demand for equipment from other businesses, so that the return is generally sufficient to meet expense, and often yields a profit.

The supposition was that the larger investment represented by motorized equipment was such as to hardly justify the purchase of machines, when the limited productiveness during five months of the year was considered, or at least this appeared to be the belief of some of the speakers. That is to say, that some coal dealers believed they could rent horses and secure such return that there would be little or no expense in their keep during the dull portion of the year, and they could hold their help as well. They were doubtful what could be done with motor trucks, although the same renting possibilities seemingly existed, but the matter of body equipment appeared to be the chief obstacle to general use.

This developed the possibilities through having special bodies, and the discussion turned to this subject, there being several body makers present. From this the speakers digressed to the prices for construction of bodies, and the builders pointed out that cost of work that was special and produced with engineering exactness and by skilled workers was necessarily more than where turned out by men who worked by "custom". Instead of being stock productions a truck body must be designed for the chassis on which it is to be used, and must have the strength to endure the service. Stock bodies can be built and kept on hand for delivery whenever required, but special bodies cannot be sold for general work.

The possibilities of building bodies that can be adapted for the requirements of general haulage and yet meet every need in coal haulage was talked over, and the body makers agreed that there was no reason why such equipment could not be supplied. One of the conditions that militate against the greatest economy of trucks being realized is the fact that as a rule the yard facilities have been built for the use of horse vehicles, and that changes necessary could only be made at considerable expense. Delivery cannot be greatly expedited because the handling of coal is incidental to other considerations. The greatest saving must be made in loading, in speed, and in greater carrying capacity, and where these can be combined the results are very satisfactory.

The Archibald Wheel Company, Lawrence, Mass., a concern well known to the motor vehicle industry as producing high class products, has been reincorporated with capital of $800,000 under Massachusetts law by F. N. Andrew, E. H. and I. M. Archibald, all of Lawrence.

C. F. Krueger, who was vice president of the Standard Electric Company, Jackson, Mich., has become associated with the Tiffany Electric Car Company, Pontiac, Mich. The Tiffany company is preparing to produce a low priced electric service wagon.

The advertising department of the Chase Motor Truck Company, Syracuse, N. Y., is now in charge of Mawee Lake, formerly of the St. Louis Republic, who succeeded Robert M. Barber.

COMBINATION SERVICE TRUCK.

Peerless Machine with Changeable Equipment an Economy in Municipal Work.

A Peerless three-ton truck is now in use in the health and street departments of the city of Boston, and after a service that has demonstrated the practicality of the equipment it has been found to be a decided economy. The saving possible with the machine has proven the wisdom of its installation, and it is not improbable that others will be purchased to replace animal vehicles that are now in use, for the truck now does the work for which several special carts would be required in summer and as many more in winter.

The chassis fitted with a dumping body and power hoist was bought with the intention of using this whenever desired, and because of the needs of the health department this was first utilized for the collection of ashes, refuse and garbage, but as the machine was primarily intended for the street department an additional equipment was procured. This consisted of a 900-gallon steel tank and as the highways must be inch hose may be coupled, and the pump will force a stream a considerable distance. This equipment is used in extinguishing fires at some distance from hydrants, and a stream of water may be forced to the roof of a four-story house. Primarily the purpose of the hose as utilized was fighting dump fires.

A three-way valve is included in the pump fitting so that the pump may be used to fill the tank with oil from a car at a railroad siding, a work formerly done with hand pumps when horse drawn oil tank wagons were used. The tank has a large manhole by which it may be cleaned. As now utilized the wagon can be used for either watering or oiling with practically no change. When distributing water the machine is driven 12 miles an hour and does the work for which three horse tank wagons were required. Then, one man, the driver, operates the machine. When spreading oil the truck is driven eight miles an hour and will spread a load of 900 gallons on 12,500 square yards of surface at a pressure of 45 pounds in 18 minutes, equalling a work for which six horses were used. After the watering and oiling has been discontinued for the year the tank and pumping apparatus is removed and

Peerless Truck Chassis and the Equipment Used at Boston for the Highway Department a Part of the Year and the Health Department Another.

oiled or sprinkled a rotary pump was installed to afford such pressure as will give equal distribution of both oil and water.

The tank is carried on a cradle of angle steel and connection is made with systems of piping so that when desired oil may be forced under a predetermined pressure through a header carried directly beneath the end of the tank. The flow of the oil is controlled by a lever that is operated by a man who is carried on a seat mounted on a frame behind the tank, and by this lever the quantity of oil distributed can be governed to meet any requirement, no matter what the speed of the machine. The pump will cause an even pressure in the tank, no matter what the height of the content. For water sprinkling a larger curved header that is mounted back of the oil header is used and the temporary seat for the operator is removed. The oil can be spread over a width of six feet with a direct downward flow, but the water is more widely distributed, covering a path about twice as wide as when used for oiling.

The water outlet from the tank to the header may be closed and another outlet utilized to which a two- with the dumping body the machine is driven 40 miles a day, making collection of refuse and ashes, doing the work of four horse drawn carts.

The H. W. Johns-Manville Company has contracted to distribute the Jones speedometers, odometers and recorders for pleasure vehicles and service wagons, and it is the intention of the company to establish well equipped stations in all localities essential to giving owners of Jones instruments immediate service or adjustments. The Jones instruments will be marketed through the 49 branches of the Johns-Manville Company and will have the personal attention of its 589 managers and travelling representatives. At these branches stations will be maintained, each in charge of a mechanic familiar with speedometer construction, and repair parts will be carried in stock. Any instrument found defective in workmanship or material will be replaced. The stations will be ready for business early in January. The Jones productions will be manufactured under the personal supervision of Joseph W. Jones, the inventor.

LEGAL ASPECTS OF FENDER ORDINANCES.

WITHIN a comparatively short time ordinances have been enacted in several cities, including Chicago and Detroit, requiring that motor service wagons and trucks be equipped with fenders. Some of these exempt vehicles carrying less than 1500 pounds, and generally provisions are made that such fenders must meet with the approval of officials entrusted with the duty of enforcing the regulations.

The question of liability of the owner and driver has always been more or less uncertain, and usually insurance that will protect the owner in the event of suit for damages arising from accident is carried. Generally this insurance covers litigation from personal injury, but in some instances it covers damages to property. The interests of the owner, the driver and the insurance company are alike in these ordinances, wherever they are effective.

Not a little attention has been given to the subject in Detroit, Mich., and with the purpose of informing the people generally of the value of the regulation in that city, and of their rights, at the request of the Wolverine Automobile Club, Attorney Cornelius T. Myers wrote the following opinion in prediction relative to the fender ordinance. This commentary is generally applicable. Incidentally, it may be said that the ordinance is being stringently enforced.

Attorney Myers' Opinion.

On Oct. 1 the police department was called upon to enforce the motor truck fender ordinance. This ordinance specifies that all trucks of one-ton capacity and over shall be equipped with a fender approved by the police department. The object of the ordinance is to prevent accidents to pedestrians, which accidents have been far too numerous of late. Several fenders have been presented to the police department and are offered for sale to our citizens who operate trucks. They resemble the various types of trolley car fenders, with which everyone is familiar.

Two questions now confront us. (1) If a truck equipped with a fender strikes and injures a pedestrian, can the owner of the truck offer as a defense the fact that he had complied with the law and the pedestrian was taking an ordinary risk? (2) Will the fenders prevent accidents?

Results from Fitting Fenders.

On the first point: It is only natural that, having been compelled by law to invest money in a fender, an owner can point to the fact that he had done all expected of him. The driver will certainly not be more careful, for he feels that having a fender to a certain extent absolves him from responsibility for an accident; also, that with a fender he has a chance of striking a person and not injuring him.

On the second point: The only thing a fender, such as can be purchased, will do, is in some cases to prevent a pedestrian being run over by the wheels themselves. Now, in the vast majority of cases the victim is injured by being struck by some part of the truck, such as the frame, mudguards, radiator or lamps (if they are on front of the truck), and thrown to the pavement or against some nearby object. With a fender attached, other things being equal, the pedestrian stands more chance of being struck because the fenders extend a foot or more ahead of the truck itself. The edge of the fender is only six inches above the pavement, so that if a person is struck with any force, he is likely to have his legs knocked from under him and thrown more violently than ever against the pavement or some part of the truck.

Causes for Accidents.

The causes of most truck accidents are fast or careless driving, ineffective brakes and (with pneumatic tired trucks) the failure to use skid chains when necessary. No amount of fenders will offset these conditions. The fender makes a heavy vehicle still more cumbersome, and adds an item of expense to the already heavy cost of hauling goods. In some cases it will be of service, and no attempt is being made to deny what usefulness it has or the public spirit that prompted the passing of the ordinance. The cure for the epidemic of accidents is deeper than the adoption of a fender. The cow catcher does not help the unfortunate New Englander who is struck by a New Haven railroad locomotive, and on the other hand, the fenders of the Detroit United Railway are seldom called upon to make a rescue. It is all a question of handling. The cow catcher is out of date and useless when called upon; the trolley fender is one of the best of its kind, but very seldom called upon. Bad management leaves railroad crossings unprotected; hence the disaster. Careful engineering has provided a safe, maximum speed and an efficient brake for the trolley car and careful training has given the motorman judgment in its control; hence the comparative absence of accidents here.

Conditions to Be Overcome.

The motor truck is comparatively a new machine and the average driver has had none too great a training in its control —neither does he fully appreciate the great forces which he is handling. Very often the truck itself is at fault, either in the design of some of its parts or in their adjustment. Heavy weights travelling at undue speeds are very hard to stop quickly without straining the mechanism or damaging expensive tires—therefore limit the speed by law and see that the governing device will not allow any greater speed. Brakes wear even when well designed and I have been on many a truck in this city where the brakes were in such poor condition as to be of almost no assistance in stopping the truck. I have seen more than one driver go day after day depending on his horn to clear the way, on nice judgment in avoiding grades, and on the other fellow's brakes to prevent a collision. Every truck should be required by law to be able to stop in a given distance when loaded to its maximum capacity.

If an ordinance is passed covering reasonable maximum speeds and stopping distances for trucks of various sizes, I think rapid progress could be made in doing away with accidents. Make inspections at given intervals, and whenever an accident takes place, have an inspection made on the spot. It should be kept in mind that nothing should be done to harm motor truck traffic, because it is of great economic advantage to the city at large, but we should guard against the great risk of accident on our streets during the development of this most modern means of transporting goods.

GENERAL MOTORS DIRECTORS.

The General Motors Company, of which the General Motors Truck Company is a subsidiary organization, will continue for the coming year with practically the same board of directors, and, assumedly, without change of policy, for Nov. 18, at the annual meeting, Joseph Boyer, Emory W. Clarke, W. C. Durant, Robert F. Herrick, J. H. McClement, Edwin D. Metcalf, C. S. Mott, M. J. Murphy, Charles W. Nash, Thomas Neal, Albert Strauss, James J. Storrow, N. L. Tilney and Jacob Wertheim were elected. Of these Robert F. Herrick of Boston was chosen to fill the vacancy caused by the death of Anthony N. Brady, and C. S. Mott, president of the Weston-Mott Company, Flint, Mich., and mayor of that city, succeeded Andrew H. Green, Jr., resigned. Emory W. Clarke was elected a voting trustee as a successor to Anthony N. Brady. The board of directors organized with the election of the following officers: President, C. W. Nash; vice presidents, W. C. Durant and Emory W. Clarke; secretary, Stanley W. Backus; treasurer, James T. Shaw; chairman of the board of directors, Thomas Nash; chairman of the finance committee, James J. Storrow.

Joseph D. Wilkinson of the Smythfield Export Company, Philadelphia, Penn., will sail from San Francisco, Cal., Dec. 12, with a party of 10 that will make a tour of the world exploiting different commercial lines. He will exhibit and demonstrate a Commerce 1000-pound wagon and has contracted for the delivery of 250 of these machines to be delivered at points to be later specified. The party will visit Australia, Asia, Africa, Europe and South America, and expects to be absent two years.

TRUCKS WORKED IN BLIZZARD.

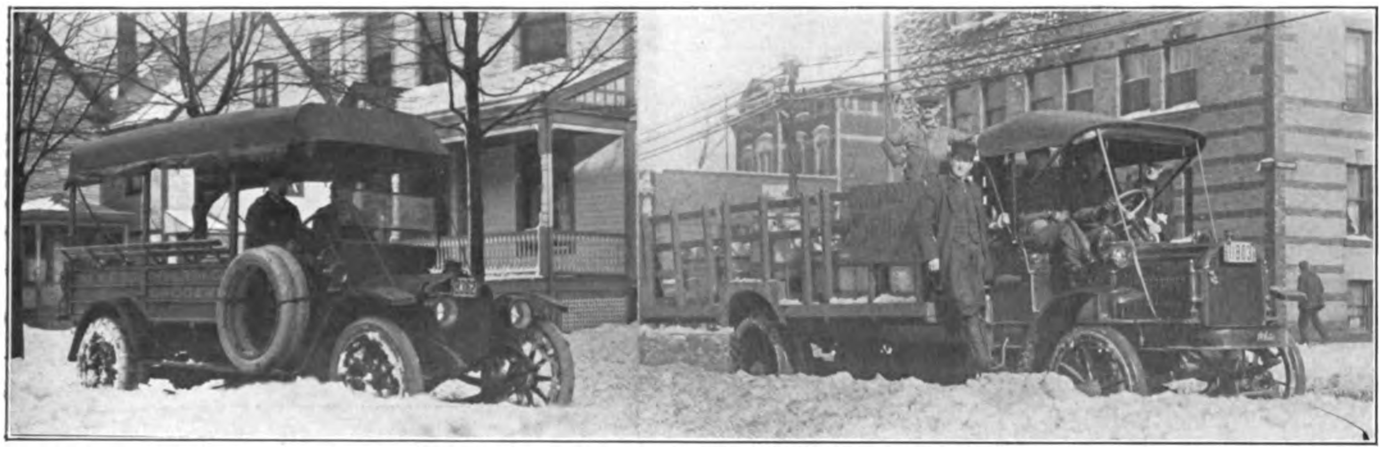
Food Distributed to Hungry Cleveland People When Other Transports Failed.

The blizzard that for three days swept the region of the Great Lakes, and extended from the Northwest to Buffalo, early in November, was most severe in Cleveland, O., where 22 inches of snow fell on a level, and this was drifted in many places to depths of five and six feet. The storm in itself was sufficient to cause great destruction, for the overhead constructions of the telephone, telegraph, lighting and trolley companies were broken down by weight of snow and the heavy wind, and the street and steam railroads were blockaded and cars and trains were stalled. Besides the snow, many streets were further obstructed by broken trees and poles and tangled wire and traffic through them with vehicles was not possible for several days, while during the storm it was at decided risk for pedestrians. In many instances the passengers were compelled to remain in stalled cars in the streets and where this could be done with safety cars were abandoned.

The storm and its hardships and destruction were serious enough, but the people, being cut off from communication with the usual sources of supply, with the railroads and streets blockaded, realized that the problem of obtaining food was one not to be lightly considered, and the actual needs of those who faced hunger called for work in the drifted snow that could only be done with motor trucks, and, in few instances, by powerful automobiles. Bucking snow that was more than axle deep when level, and sometimes higher than the machines when drifted, movement through the streets was only possible with motor vehicles when traction could be obtained.

By the end of the first day railroad traffic had practically ceased and streets were nearly impassable for animals. The second day, business was paralyzed and people were confined to their homes, and by the third day shortage of food caused a situation that was almost alarming. The shortage of milk, because of the blocked railroads and freight yards and the impossibility of distributing what was brought into the city, was indeed serious, and hundreds of people waded through waist deep snow to reach the depots of a large dairy company, where they waited in line for hours to get milk brought in by White five-ton trucks from milk trains stalled outside the city. The food stores were called upon for whatever was edible, and by the end of the third day the stocks were practically exhausted. The renewal of stock was dependent upon wholesalers making delivery.

At this time most of the vehicles that could be moved were laden with food. Motor trucks and wagons were kept moving under conditions that required the best that was in both machines and their crews, and many of the drivers proved to be real heroes, in that they endured great hardships, as the firms having machines kept them constantly at work. At best the mileage and load capacities of the motor vehicles were reduced, but work with them was always possible. Two of the largest wholesale grocers, operating 12 White trucks, made deliveries to many stores within a limited radius, but hundreds of retail establishments in the city and suburbs were without food stock until the streets were passable for other vehicles.



During the November Blizzard That Centred in Cleveland, O., the Food Supply Was Nearly Exhausted, and Great Hardship Was Averted by Distribution with Motor Trucks.

The American Glycerine Company, manufacturer of nitroglycerine, has installed in service at Findlay, O., a Commerce wagon that has been specially fitted for the transportation of this explosive, which is used by those operating in the oil fields for "shooting" wells and increasing the flow from them. Because of the danger from explosion extreme care must be taken in handling nitroglycerine, and special provision is always made for the protection of the workers. The Commerce wagon is fitted with a cradle that will practically absorb all shocks from the road and minimize their effect upon the load, which is, at maximum capacity, 840 pounds. In this machine the explosive is carried long distances and with a greater degree of safety than would be possible if it were transported by any other form of conveyance.

HIGH GRADE SELLING STATEMENTS.

THERE can be no subject of greater interest to the motor vehicle industry than promotion that will practically benefit it, and primarily this means that there must be argument made that will convince and establish confidence in motorized equipment, for unless there is conviction that motor wagons and trucks are practical nothing can be gained by discussion. Naturally consideration of the qualities that make for economy must be in the nature of selling talk, and whatever is stated should be broadly promotive and not of a character that will cause doubt in the minds of those who are studying or investigating the subject.

Much attention has recently been given by different business and trade organizations to policies that will impel attention from the soundness of the statements made, and which will, while establishing the merits of any given product, have the value of promoting the use of power wagons generally instead of causing distrust of all other vehicles than that directly discussed. Fundamentally there is need of methods and presentation of facts that are educational, which can be broadly applied and are yet sufficiently specific to be associated with the conditions generally obtaining with industrial or commercial enterprises.

There are those who believe in the utility of electric vehicles, and those who build these machines devote careful study to the presentation of statements that will be promotive of their use. Education of the people is essential, and where those who are interested cannot be conveniently reached by salesmen there is imperative need of such systematized representations as will convince. Misrepresentation would be destructive and conservatism is better than ill-advised enthusiasm.

An admirable example of high grade salesmanship is subjoined, it being a communication prepared by A. C. Downing of the Anderson Electric Car Company, Detroit, Mich., which is sent to inquirers who seek information relative to the Detroit electric vehicles. This is broad gauge and well founded, and it will be noted that this policy can be applied equally well to any make or type of machine with, assumedly, equally satisfactory results:

The Electric Vehicle and Its Service.

The world's business depends almost entirely upon the transportation of merchandise from producer to consumer. City and immediate suburban transportation is increasing with wonderful strides. The passenger automobile has made it possible for a family to live in a suburban district and yet transact business in, and depend upon, the city for supplies. Further, the improved street railway, interurban lines and subway roads have increased the area of our cities; therefore, a merchant, to keep pace with the times and for the purpose of giving his patrons service, must have a delivery equipment capable of covering a great number of miles per day. The improved streets and roads aid materially in the successful working out of the self-propelled commercial vehicle. Under these new conditions the horse drawn equipment is working at its lowest efficiency while the self-propelled vehicle is at its highest.

The first successful self-propelled commercial vehicle was the electric. With the increased knowledge of batteries, motor and general construction the electric commercial vehicles of recent years are unquestionably accepted as the most efficient, reliable and economical for general city and suburban service. The great number of recent installations have performed in such a manner as to fully confirm and credit the performances of electric commercial vehicles installed 10 or 12 years ago.

Changed Conditions.

The general reduction in the price of electricity for power purposes has greatly broadened the field for electric vehicles. The improved streets and roads above mentioned have also increased their possibilities. The demand for reduced speed in merchandise transportation has brought the electric back into its own. At first the opinion was that the electric vehicle was not of ample speed, but continuous service and numerous tests and trials, along with the municipal regulation of speed, have proven conclusively that high speed is not practical or necessary to make time where the stops are more or less frequent.

Drivers.

Drivers in the majority of cases should be men trained in the handling and delivery of a certain kind of merchandise. Using for example the furniture business, a customer might become completely dissatisfied if the goods purchased were not placed in her house so as to make a favorable first impression. With the electric car your regular trained driver can be instructed in a very few lessons as to the successful handling of the car, as its simplicity in operation and care does not necessitate an especially trained man.

Further, in a limited equipment it is possible for two or three men to know the operation of the car, so a delivery service is not crippled in the case of illness of the regular driver. The expense of having an extra man on the car to handle the goods is not necessary unless the business requires two men in order to increase the efficiency of the vehicle, by reducing its time idle.

For a large installation where the personal qualifications of each and every driver are more or less of an unknown quantity the electric machine has proven the most satisfactory, as its successful working out is not dependent upon the individuality of the driver. In other words, the operator of the electric vehicle does not materially affect it provided he will guide the car and use his brakes with judgment and think about the expedient delivery of his goods.

Garaging.

There are numerous installations of 20 to 25 cars which are kept in excellent condition by four men. This includes the washing, oiling and charging of the cars daily, making all minor repairs and adjustments, and complete care of the batteries. In some larger installations 50 or 60 cars are garaged by six or seven men. In one or two-car installations it is possible for the driver to wash, oil, charge and adjust his machine, and then for major work or annual overhaul, the services of a local garage may be called upon. Where five or six machines are owned by a firm it has been found expedient and economical to place them in the charge of one man who has ample time to keep all in A 1 condition ready for daily service. One concern in particular has had 10 machines in the hands of two men, with an excellent record for care, attention and service. These men have cared for the machines for three years without need of additional help, thus fully proving that the age of electric vehicles does not mean an increase in labor to keep them operative.

Insurance.

Insurance companies make no discrimination in the rates of warehouses or buildings in which electric machines are garaged. This feature has made it possible for many merchants to keep six to 10 machines in their warehouse and thus reduce to a minimum the expense of floor space, and at the same time have their affairs more centralized. In one, two or three-car installations this plan is especially valuable, as the night watchman can keep in touch with the cars should there be any special points to be watched.

Rents are naturally high in the larger cities. One electric vehicle requires very little more space than a horse drawn wagon of equal capacity, thus the space required for horse stalls, hay mows, harness and feed rooms is saved. In addition, an electric commercial vehicle is capable of doing the work of two (sometimes three) horse drawn rigs. At a glance the importance of this item is seen. As to space for repair shop and stock room, electrics require the minimum as their requirements in this direction are very slight.

Why Efficient for City Use.

The ability to make frequent stops and starts places the electric vehicle in a field by itself for service in congested districts. All tests to prove the above statement have clearly shown that no matter whether the electric vehicle is running up or down hill, or on the level, wherever stops and starts are more or less frequent the speed remains very close to constant and averages higher when compared with any other method of transportation, no matter what the speed possibilities may be. This feature is due to the rapid acceleration of the motor and simplicity in operation of the controller. One essential point of the electric vehicle is in the non-use of power while the vehicle remains idle for short periods.

Life and Operating Expense.

The life of the electric vehicle may be figured, with a certain degree of accuracy, at 10 years. This is not conjecture, but a fact, based on absolute records and daily working examples. With a limited amount of money spent at the proper time for mechanical upkeep there is no excuse for a properly designed electric vehicle ever becoming completely disabled, barring accidents, of course. Nor is there any reason for the upkeep cost ever becoming prohibitive. To prove these statements pick up the dealers' lists of second hand vehicles, ex-

amine the advertisements in the daily or trade papers, or try to buy a second hand electric commercial vehicle from any source and you will be convinced as to their remaining in service and efficient; otherwise many would be for sale.

Mechanical Make Up.

The electric motor of ample size and proper design has an indefinite life. A controller of proper proportions for a given motor should represent an equal life with a very limited expense for upkeep. The wiring if installed in conduits and properly anchored should never cause trouble unless it be badly injured. The frame of an electric vehicle chassis is made of all steel, which will never wear out, and the springs, if made of proper steel and bushed at the eyes, should last for years. The axles, front and rear, should not need renewal, as bearings take up the wear and they are easily replaced. The steering knuckles are fitted with bushings, which can be replaced, and the pins, if hardened and ground, should last two or three seasons when properly lubricated. The shackle bolts, steering tie-rods, brake shoes, brake linings, brake rods and springs for the vehicle throughout should represent a very limited yearly expenditure. The type of drive would govern to an extent the cost for power transmission parts, and this expense is governed largely by the care of the machine as to necessary adjustments and lubrication.

Battery.

The battery can be figured at a certain cost per mile, with or without current. Batteries having a guaranteed capacity and life are now sold. There is definite knowledge as to the amount of current necessary for a full charge, and, where operating conditions are known, the number of miles a car makes per charge can be divided into an average daily battery expense and the cost per charge, thus giving a fairly accurate daily or per mile upkeep and operating cost. Further, with the life and capacity of the battery guaranteed the buyer is insured against an excessive upkeep cost. This point is particularly valuable where a machine is to be installed and cared for in a private garage or where several vehicles are to be looked after by one man, when especially trained help is not feasible.

Tires.

The tires on the electric commercial vehicle are of the solid type. Their use is practical as the speed of the electric machine is within range of this construction; and also the total absence of delicate parts and bearings permits the use of solid tires. This practise adds reliability and stability, to say nothing of the lower cost of upkeep. With solid tire equipment the driver is not to be delayed in his work on account of blowouts, rim cuts or punctures. With the standard S. A. E. band, as universally adopted by truck and tire manufacturers, the renewal of solid tires can be quickly made.

Service.

The subject of reliability previously mentioned interests the owner or prospective owner of commercial vehicles. An employee of irregular habits is not tolerated in any business for a moment; neither can this irregularity be tolerated in the transportation department of any business, as so many things are dependent upon prompt service. Any number of electrics have records of 295 to 300 days' service per year out of a possible 312. Where bodies do not require particular painting less time is lost. Several instances of constant daily service cover 18 to 24 months without a miss. Such records are due entirely to the simplicity and accessibility of parts entering into the electric's make up.

For example, the motor can be taken out and replaced in two hours' time by two men. Should a controller finger or plate become worn or burnt, another can be replaced in not more than 30 minutes. The axles, countershaft, steering mechanism and brake parts are common to all self-propelled vehicles; hence, electrics are at no disadvantage in this respect. Batteries can be replaced as a unit in 30 minutes, or individual cells removed and repaired during the night with no lost time recorded.

A concern in a central western city has been operating 20 electrics for the past six years. As its business demands daily service it figures 10 per cent. additional vehicles enough to warrant the required service. One machine is held in readiness to relieve another in case of accident and another is always in the paint shop for annual overhaul. During the peak of the holiday trade these extras are pressed into service and thus materially help pay their way.

Summary.

This discourse may be rather lengthy, but the writer has tried to cover in general the "whys and wherefores" of the electric commercial vehicle. The points touched upon are usually outlined in catalogues and circular letters, but in a meagre manner. If you were in doubt as to what power to purchase and it were possible for the writer to talk personally with you, his arguments would be along the lines of the foregoing.

The first cost of electric commercial vehicles properly equipped is greater than other equipments, but they will pay interest on their investments, stand the depreciation (which is low), pay for all upkeep, insurance, taxes and driver's wages, and still show a material saving over other methods of transportation working under given conditions.

Electric vehicles are much like humans—for a long time they will silently stand overwork, inattention and abuse, but finally give in. On the other hand, if electric vehicles are properly loaded, handled with judgment, lubricated and kept in adjustment, their life will be one of long service at low cost.

FREIGHT TRANSFER BY TRUCKS.

New Haven Road Installs First of General Vehicle Fleet at Boston.

The New Haven railroad system, which centres in Boston, controls two terminal stations, the North, which is used by the Boston & Maine, Fitchburg and other lines extending north and west, and the South, which it shares jointly with the Boston & Albany road of the New York Central system. There is a freight yard, with the receiving and delivering houses for each terminal. There is no connection between the two, and freight and baggage billed or checked from points on either system to points on the other must be transferred across Boston, from the one freight yard or station to the other.

This condition resulted from the fact that originally there were a number of roads, each independent of the other, but uniting in two main passenger stations. Later two stations were erected, the one for the Boston & Maine and the other for the New Haven road. As the traffic and the volume of freight and baggage to be transferred has increased from year to year the New Haven railroad has found street and terminal congestion during the working hours of the day and the limited capacity of animal vehicles a serious handicap, the expense and the delay becoming problems that required careful consideration.

The company's transportation engineers studied the conditions and made recommendation that trucks of large capacity be used, these to be largely utilized in haulage from one terminal to the other, and the work to be so systematized that loads could be carried both ways. With this purpose in view the company has ordered a number of General Vehicle machines which will be delivered as rapidly as possible. The first of these has been delivered and is now in service. They are fitted with bodies that will permit capacity loading when the freight is bulky, and the loads can be protected from storm. The haul from the one freight yard to the other is approximately a mile, and the machines can be worked as many hours as desired each day by an exchange of batteries should the normal mileage be exceeded. The intention of the company is to use as many trucks as shall be necessary. So far as is known this is the first instance of a railroad company in America using trucks in transportation, and the result is being watched with a great deal of interest by Boston business men.

Hugh Warner, formerly with the Warner Gear Works, Muncie, Ind., has been engaged as designing engineer by the Detroit Standard Gear Works, Detroit, Mich.

A company is being promoted in Detroit, Mich., by Peter Steenstrup, formerly sales manager of the Hyatt Roller Bearing Company, to sell the Livingston pressed steel wheel.

PARCEL POST DELIVERY.

White and Wagenhals Machines Purchased by Government for Special Service.

The United States Postoffice Department is now using 40 machines for the collection and delivery of parcel post packages in some of the principal cities of the country, and the results from the use of these will very largely determine the plans of the department for handling this division. The parcel post service was inaugurated Jan. 1, 1913, and each day the volume has increased, so that the department has been forced to provide facilities for collection and distribution as these needs have been realized, instead of making provision based on experience and knowledge of probable requirements.

With the public demanding prompt and satisfactory handling of parcel post packages the department has authorized the use of motor vehicles by contractors carrying mail and in some instances has permitted postmasters to make supplemental or provisional contracts for collection and delivery. The purpose has been with such service to make careful observation and record for the guidance of the department in determining needs and efficiency, and in a considerable number of cities what may be termed experimental work is progressing.

Mail carrying contractors have the option of purchasing or using whatever machines they believe will serve their purposes, and no restrictions are made, but when the government purchases its own equipment it specifies every detail, and the vehicles must conform to these. Thus far the Postoffice Department has made but two purchases of machines, making one contract for the delivery of 20 White 1500-pound delivery wagons with bodies that are completely enclosed, affording protection of the mails from storm and insuring against theft. These wagons have been delivered and they have been assigned to different cities where conditions have required increased facilities. These machines are located in some of the principal cities and are now giving excellent satisfaction.

The government has also purchased 20 machines from the Wagenhals Motor Car Company of Detroit, Mich., these being equipped with special bodies regarded as being adapted for collecting and delivering parcel post packages. These vehicles were ordered after careful investigation of the work accomplished in service in Detroit and other cities, and records showed that they were in every way reliable and dependable.

The Wagenhals machines are of the type generally known as tricars, such as are extensively used abroad, and have been developed with a view to hard and exacting service. A considerable number of patents cover the construction of the vehicles and these are maintained to be of special value with reference to economy and endurance. These wagons are made in one size only and have capacity of 800 pounds. They have motors of 20 horsepower and the claim is made that they can be operated with a large measure of economy. The body equipment is varied to meet the requirements of the purchaser.

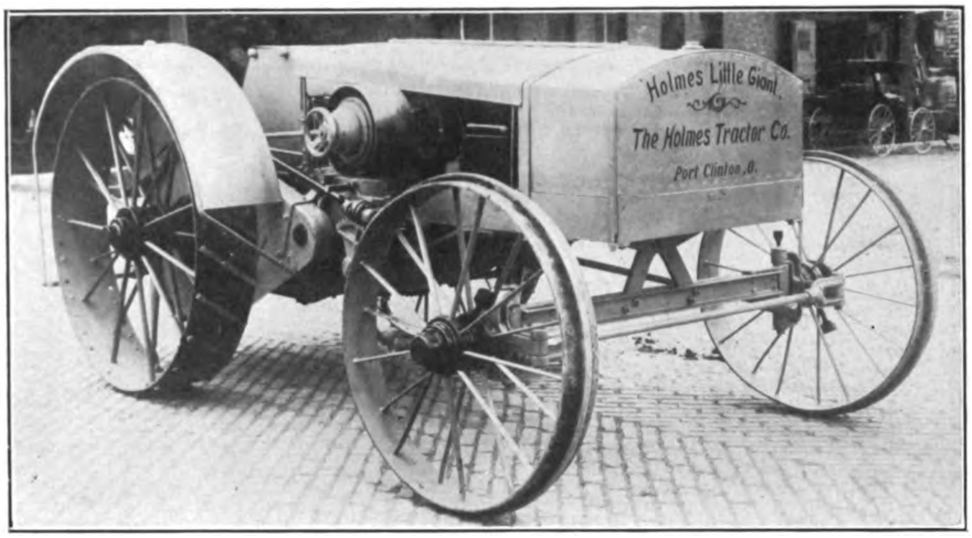
The two types of machines, which are illustrated, have been regarded as meeting the requirements of the parcel post division, the smaller vehicle being suited for routes where the weights are small, such as for rural delivery, and the other for work within communities of proportions. As now used they are attached to the service in different cities and are operated for many hours daily, for deliveries are made during one portion of the day and collections another, extending the day's period of usage to from 15 to 20 hours. The volume of business of the parcel post division is steadily increasing and the reserve capacity and endurance of the machines is absolutely necessary to insure economy in serving the people. With any other form of equipment these qualities can only be obtained by maintaining extra equipment or hiring it when needed.

The United States Postoffice Department Has Purchased 40 Machines, 20 Each of the Types Shown, for the Collection and Delivery of Parcel Post.

The Weston-Mott Company, Flint, Mich., has just occupied a new building, 320 feet long and 75 feet width, one story and monitor roof, which is absolutely fireproof, the material used in the entire construction being metal or concrete.

HOLMES LITTLE GIANT FARM TRACTOR.

THE Holmes Tractor Company, Port Clinton, O., is building a tractor, designed especially for farm purposes, that has many qualities to recommend it to those who have need for a machine that will do the work for which horses are used, and which can be utilized as a power plant for husking, shredding, pumping, grinding, sawing wood, and in fact, for any service for which a stationary engine may be required. The machine is not built for passengers, but it is constructed for work on cleared land that can be cultivated, and it can be driven in fields for plowing, harrowing, seeding, harvesting, and on roads it will haul trailers. The capacity of the tractor is maintained to be equal to that of two two-horse teams for field work, and on the road it will do more than two teams when trailers are used. The builders claim that it will do all the work necessary on small farms and all the light work on large farms, and that it is especially adapted for service in orchards.



The Holmes Little Giant Tractor, Designed for Agricultural Service and Used as a Portable Power Plant.

The tractor has been perfected by two years of experimental work and it has been constructed with a view of long endurance in all conditions of practical operation. The design is exceedingly simple and all parts are made with a large margin of safety. The mechanism is very accessible so as to minimize care and attention, and the parts are interchangeable and can be replaced readily whenever this is necessary by anyone who is not experienced in mechanical work. The tractor has a low centre of gravity, small turning radius and it can be used on ground that is comparatively rough.

Tractor Weighs 4400 Pounds.

The tractor is 138 inches length over all and is 72 inches width, and is 54 inches height. The weight is 4400 pounds. The chassis frame is constructed of steel channels, with sturdy cross members, the assembly being hot riveted. This frame is mounted at the forward end on an I section axle which carries a triangular bracket, at the apex of which is a trunnion on which the axle may swing, so that with one front wheel elevated or depressed there is no strain on the chassis. The rear end of the frame is mounted on springs and the drive from rear axle is through radius rods.

The water tank is carried at the extreme front end of the chassis frame and back of this is the motor, which is a conventional four-cycle, water-cooled, two-cylinder opposed type, with cylinder bore of 5.5 inches and stroke of five inches. This is rated at 12 horsepower by the maker, but it is rated at 14.2 horsepower by the S. A. E. formula. The engine is a standard construction and has a normal speed of 750 revolutions a minute. The crankshaft is heavy and is mounted in two long bearings, and by removing the crankcase cover plate the connecting rod bearings may be exposed. The timing gear is carried in a cage that is bolted to the engine case under the cover plate.

Adequate Lubrication Assured.

The engine is lubricated by a mechanical oiler that supplies oil to the main bearings and connecting rods, and the camshaft, valve tappets, timing gears, and the cylinder and piston walls are oiled by splash. The feed is positive and the connecting rods are insured adequate lubrication by a special device. The ignition is jump spark by current from either dry cells or a storage battery intensified by a coil. The normal fuel capacity is 25 gallons of gasoline, which is sufficient to drive the tractor for several days, as the working speed is estimated to be about 1.75 miles an hour.

The motor is mounted longitudinally in the frame with the crankshaft extending transversely, and on this, outside the flywheel, is the driving sprocket and the power transmission gearset. The gearset is a planetary type, affording two forward speeds and reverse, and the speed ratios are obtained by the usual hand lever. The drive to the jackshaft is by a chain from the engine shaft, the chain extending to a differential gear mounted on a sleeve. The main jackshaft extends through the sleeve and the drive is from one side through the sleeve and from the other through the shaft by sprockets and chains to sprockets on the rear wheels. The differential case is oil and dust tight and the gears have wide faces and are cut from grade steel. The jackshaft is carried on long roller bearings mounted in hangers that are adjustable, there being provision for ample lubrication. The driving chains are protected by chain cases.

The front wheels are 36 inches diameter and have

steel rims five inches width, in the centre of which is a ring that extends around the circumference, this preventing side slip. The rear wheels are 40 inches diameter and have steel rims 10 inches width fitted with diagonal cleats across the faces, these affording traction on any yielding surface. The wheels have steel hubs and steel spokes and are built with the spokes set in two series, separated practically the width of the hub and closer together when fitted in the rims. The front wheels are mounted on spindles that are pivoted in the yokes, following conventional automobile construction, and the steering gear is the usual linkage, controlled by a worm and sector and a steering column and hand wheel extending to the rear of the chassis.

Convenient Control Levers.

At the rear of the tractor, suspended from the chassis frame, is a platform, on which, directly behind the steering wheel, is mounted a seat such as is usually fitted to regular farming machinery, and convenient to this are the speed changing and the spark and throttle levers. The engine is usually controlled by throttle, but a hand adjustment can be used should there be need of less or greater speed than the normal control will afford. On an extension of the engine shaft at the right side is mounted a 12-inch pulley with six-inch face, from which a belt can be driven when the tractor is to be used as a power plant, and as the tractor can be blocked it will supply power up to its capacity and for any length of time required. The water tank will contain 40 gallons and the cooling system will prevent overheating no matter what the period or the conditions of service. The chassis is covered with a removable metal hood and the machine is fully protected.

The tractor is not unsightly as compared with farming machinery, but service and endurance, and not appearance, is the principal purpose, for polished metal and fine finish is lacking. The machine has been worked on grades up to eight per cent., and on the greatest gradient it has been more than equal to four horses for hauling. The road speed is about four miles an hour.

Showing the Holmes Little Giant Tractor Used as a Power Plant for Farm Work.

Plowing with a Little Giant Tractor, the Machine Replacing a Horse Team.

WILL BUILD HEXTER TRUCK.

The Roland Gas-Electric Vehicle Corporation, with capital of $200,000, the stock being half preferred and half common, has been organized by P. K. Hexter, Ronald R. Conklin and Sidney L. Conklin of New York City, and a factory has been secured at Avenue B and 20th street, where it is purposed to build gas-electric trucks of three and four tons capacity. The factory will be managed by Mr. Hexter, designer of the machine, and plans made comprehend the production of 100 machines the first year.

The chassis will have a 136-inch wheelbase, standard tread, and will be carried on 36-inch front wheels and 40-inch rear wheels. The power plant will be a gasoline motor of the four-cycle, water-cooled, T head type, with cylinder bore of 4.5 inches and stroke of 6.75 inches, lubricated by combination force feed and splash, and having magneto ignition with automatic spark advance. This motor is carried in a sub-frame. The fuel supply is governed by a foot accelerator. An electric generator is mounted in the sub-frame and this is connected with the flywheel end of the motor shaft by a flexible coupling. The generator is a 7.5 kilowatt, compound-wound machine. The generator is turned at engine speed, producing at 900 revolutions 60 amperes at 125 volts. From the generator the current is supplied to two motors mounted on the rear axle, each driving one wheel. Through the variance of the engine the speed of the truck may be controlled between an eighth mile and 15 miles an hour.

The Republic Rubber Company, Youngstown, O., following out the policy of direct selling it has established, has acquired control of the Republic Rubber Company of New York and will continue the business of that concern at 229 West 58th street, New York City. F. G. Hill, who was secretary and sales manager of the former company, continues in charge of the tire sales, and C. W. Hardin, who was eastern manager for the Republic Rubber Company, has taken charge of the mechanical sales as vice president and treasurer.

DEPARTMENT STORE DELIVERY ECONOMY.

THE experience of the Sterling & Welch Company, Cleveland, O., one of the largest concerns of that city dealing in furniture, carpets and household furnishings, with motor delivery equipment, which was begun in May, 1910, has very conclusively demonstrated that with good organization and careful supervision, not only can extreme satisfaction be obtained, but the business done can be extended and customers served in an area that could not be covered with any other form of transportation. The company now has 10 motor wagons in use, the number being increased as efficiency became assured, and the economy attained has been in every way gratifying.

Of ten machines in service seven are White wagons, three of 1500 pounds and four of 3000 pounds capacity. The first purchased were two White vehicles of the larger type. In May, 1911, two more were bought, and in April, 1912, the three smaller wagons were acquired. These chassis were fitted with bodies adapted for carrying furniture, these having standing tops and side curtains to protect the loads. All of the equipment is shod with pneumatic tires.

Four of the Fleet of Seven White Delivery Wagons in the Service of the Sterling & Welch Company's Department Store, in the City of Cleveland, O.

The company took up the delivery problem with care and with methods that promised to yield economy and efficiency. First of all it selected horse drivers and trained them in the operation of the wagons. It established a garage and fitted it with such equipment as was necessary to maintain or repair the machines, and employed a man whose duty it was to see that they were always in condition for service. Provision was made for expansion as the number of vehicles was increased, and system was adopted that would insure accurate knowledge of the work done and the expense of operation and upkeep.

While the company's garage is not distant from the White factory, none of the wagons has ever been sent to the maker for work, the garage force being capable of doing whatever has been found necessary, and the character of supervision and careful driving has minimized the labor and attention required to keep them in fine condition. For instance, in November, 1912, after three of the wagons had been driven approximately 40,000 miles each and they had been in service about 2.5 years, they were overhauled and completely restored at a cost of about $100 each. The depreciation is estimated at 20 per cent. a year, but the results with these were such as to indicate that a much longer period of service could be obtained with them.

One of the wagons first bought was recently overhauled, after being driven 65,000 miles, in 3.5 years, and the cost of parts used in restoration was $35, despite the fact that the machine had been driven for what was believed to be 70 per cent. of its life. The pneumatic tires used have been driven an average of about 4000 miles.

The company makes delivery in Willoughby, 19 miles east; in Dover, 14 miles west, and in Brocksville, 15 miles south, and to all localities between, so that these distances do not give an accurate idea of the mileage driven. Each wagon is assigned to a route and it is required to serve this, making direct deliveries from the store or warehouse to the customer. The machines make two trips daily and because of the character of the goods carried a half hour is allowed for loading, this taking an hour from the day's service time. The drivers report at the store at 7 in the morning and return about 5:30 from the second trip, averaging about 8.5 hours in covering the routes, but all of this time is not required for driving, a considerable part being given over to unloading, setting up furniture and the like, which is required by the customers.

The wagons are driven an average of 62 miles daily and make 65 stops, so it will be seen that a greater portion of the time is taken up by intervals of idleness than might be believed, for did the stops average but three minutes each this would account for more than three hours. The company's officials believe that from 40 to 45 horses would be necessary to do the work that is now done with the trucks. But the greater radius of delivery is extremely important, for it has materially increased the patronage and it is evident that to go further than 10 miles from the store with animals would not be economical. The delivery depart-

ment is in charge of an expert of long experience, who is progressive and does not hesitate to make changes when the service will be improved. The fact the company has trained its own men, who have long experience in handling its goods and realize their own responsibilities, is a very important factor. The men are well paid and work for the interests of the company, both while driving and in handling and delivering the freights they carry.

CANFIELD PATENT IS VALID.

A. R. Mosler & Co. Obtains Injunction Prohibiting Sale of Infringements.

A decision by the United States district court of appeals in New York City, made by Judge Lacombe and concurred in by Judge Ward and Judge Rogers, in the suit of A. R. Mosler & Co., against John Lurie, maintains that the Canfield patent, owned by the complainant, is valid and the defendant is enjoined from selling the six different makes of spark plugs named in the bill of complaint. The attorney for the complainant, W. A. Redding, claims that the decision is very broad and that it will affect practically every maker of spark plugs.

The Canfield patent is the invention of Frank W. Canfield, engaged in lumber trade at Manistee, Mich., the papers establishing it being issued Oct. 18, 1898. He died the following year. The patent was acquired by the Associated Patents Company, which organization was affiliated with the Association of Licensed Automobile Manufacturers. The association licensed each member to use the plug and then sold the patent to A. R. Mosler & Co.

Lurie was proprietor of the Automobile Supply Company, New York City. The suit for infringement was begun in 1909 and it was dismissed in the United States circuit court by Judge Mayer. An appeal was taken and this has now been decided. The principal claim is for a recess in a spark plug surrounding the central electrode to prevent the accumulation of soot or carbon, this recess being necessary to insure a full spark and prevent a short circuit.

The Muncie Gear Works, Muncie, Ind., which had been conducted by a receiver for a short time, has been reorganized, the capital increased from $300,000 to $500,000, and these officers elected: President and general manager, Thomas W. Warner, Toledo, O.; vice president, Dr. W. A. Spurgeon; secretary-treasurer, J. Roy Goethus. Hugh L. Warner and D. O. Skillen have retired as vice president and secretary-treasurer, but continue their interests in the company. Creditors have accepted preferred stock to the amount of $230,000 in settlement of their claims, and cash settlements to about $35,000 have been made with others. The company has resumed operations at its old plant.

REACHING THE INQUIRER.

Electric Vehicle Association's Handbooks for Investigators of Haulage Data.

The Electric Vehicle Association of America, which has for the past two years conducted a campaign for the general promotion of the electric vehicle for pleasure and service purposes, has published two booklets which are available for distribution by the secretary to all inquirers, or which may be circulated by the members of the organization to those who might be interested in the subject.

These booklets are entitled "The Story of the Electric Pleasure Car" and "The Story of the Electric Commercial Vehicle", the former being 24 pages and the latter 36. They are cleverly designed, carefully illustrated and the typographical work is decidedly effective. The booklets are similar in character and general makeup, but deal with different subjects. That devoted to the commercial vehicle introduces the importance of haulage problems and then considers briefly electric machines and their reliability and efficiency as demonstrated by experience covering a period of about 15 years, and by instances of continuous service for 10 years or more for firms of national repute. Attention is given to the development of electric service wagons and trucks from the viewpoint of engineering, and the remarkable progress made in battery construction, establishing the claims for efficiency and endurance at low operating expense, and emphasis is made of the very rapid adoption of these machines. Last, but not least, the constantly lessening cost of electric current is shown.

Under the caption "The Electrical Commercial Vehicle of Today" the economy of electric vehicles is briefly explained and examples are given of the experience of concerns that are realizing the fullest measure of return from scientific transportation methods and the best equipment obtainable. Then follows estimates of cost and salient facts relative to service and reliability. Comparisons of operating expense estimates for electric machines and animals in varying service are of decided interest. The booklet contains illustrations and brief specifications of some of the machines built by those who are subscribers to the general publicity fund of the association. The booklets are free to all who are interested sufficiently to make inquiry of the secretary of the Electric Vehicle Association, 124 West 42nd street, New York City.

The Front Drive Motor Company, which was organized by Walter Christie to build tractors to use with differing forms of equipment, and which has been located at Hoboken, N. J., for nearly two years, may remove to Erie, Penn. Most of the tractors built have been utilized for fire department work, principally for hauling engines and ladder trucks. A considerable number of these tractors are in service in New York City.

CARTER PISTON VALVE MOTORS.

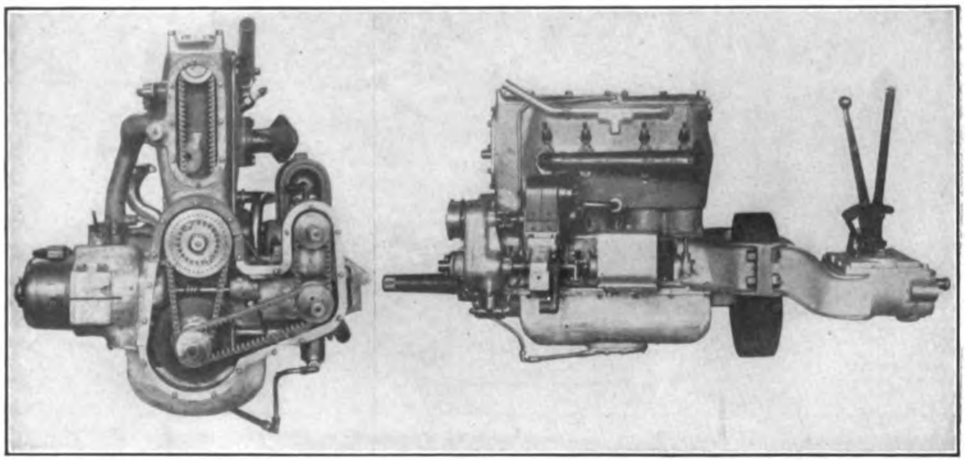
THE Carter piston valve motor is now being built by the Model Gas Engine Works, Peru, Ind., in a single size, but it is the purpose of the company to produce this engine is several sizes in a factory that is now being developed at Pittsburg, Penn. The motor is designed for use in all types of motor vehicles and the claim is made by the maker that the efficiency is considerably higher than is obtained with engines of conventional types of the same proportions. In other words, the power plant is lighter at the same power than the usual forms of poppet valve engines.

The motor differs from others very generally in appearance, but as will be seen by the line drawing the only variation from established principles is in the use of the valve mechanism. The illustrations are of a size now being built at Peru, and this is a four-cycle, water-cooled engine with cylinder bore of 3.75 inches and stroke of 5.75 inches, this giving a bore to stroke ratio of 1:1.652. This has a rating by S. A. E. standard of 22.5 horsepower, but the engine will develop 30 horsepower or better at maximum capacity, for increased efficiency is claimed as a result of the use of the valves.

The valve mechanism is decidedly at variance with recognized construction standards. The cylinder is bored straight through, as may be seen in the drawing, and into cylinder head the second piston is fitted. The piston carries three compression rings, practically the same as the power piston, and on the extension at the base of this piston two expanding rings are fitted. These are designated in the drawing as A A. These rings close the intake port C and the exhaust port D and serve the same purpose as the ordinary poppet valve. The upper piston is actuated by a camshaft, and the cams E E and F, practically the same as poppet valves are operated. The camshaft is placed across the top of the cylinders, both the cylinders and pistons being slotted to receive it.

The upper piston is fitted with a standard wristpin, shown as G, and a roller H, which contacts with the centre cam F. The bridge I across the top of the piston contacts with the two outside cams represented as E E. The outside cams E E are in duplicate and are ground so that they are in contact with the bridge at all times, and the centre cam F is also in contact with the roller H at all times. The cams are so ground that each movement of the upper piston corresponds to that of the ordinary poppet valve of the standard motor. This insures positive movement of the piston valve in either direction.

Considering the operation of the motor, on the suction stroke the vacuum is created that will cause the upper piston to follow the power piston to a position where the cam serves as a stop, or practically "times" its movement. As the power piston is forced upward on the compression stroke the compression serves to lift the upper piston, the cams again serving as a stop and definitely placing it. Near the end of the explosion stroke the pressure on the upper piston is sufficient to not only raise it for the opening of the exhaust port without the service of the cams, but actually exercises sufficient energy to materially relieve the camshaft driving mechanism. With a six-cylinder motor the energy is enough to drive the camshaft so that the driving mechanism merely controls. It is noticeable that at no time do the valve ports open against pressure, so that whatever wear there is is on the cams, and is on the heel, or on that part that is receding from the corresponding wearing surface.



The Carter Piston Valve Motor: At Left, the Timing Gear Case, Showing the Silent Chain Drive of the Camshaft, Water Pump, Magneto and the Worm and Gear Driven Motor Generator; at Right, the Unit Power Plant, Exhaust Side.

The effect of the operation is stated by the maker by comparison with a poppet valve motor with cylinder bore of 3.75 inches with a 1.75-inch valve lifting .375 inch, the piston valve motor having the same cylinder bore and a port .15625 inch extending completely around the cylinder with the exception of .75-inch allowance for the lap of the ring. The total area of the poppet valve is 2.06 inches and of the piston valve 1.75 inches. The time required for the full opening of the poppet valve from start, in crankshaft revolution, is 102 degrees; time required for the full opening of the piston valve from start, in crankshaft revolution, 62 degrees. The "time" required for different degrees of opening of both types of valve is stated as follows:

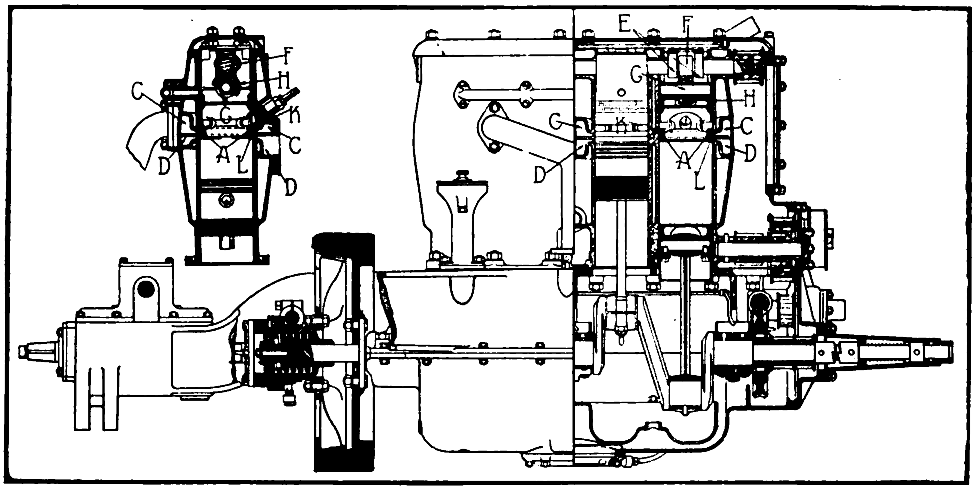
Opening	Poppet Valve	Piston Valve
Full	102 degrees	62 degrees
Half	58 degrees	21 degrees
Quarter	40 degrees	15 degrees

Degree "Time"	Poppet Valve Equal	Poppet Valve Area	Piston Valve Area
23	.03125 in.	.17 in.	1.10 in.
34	.06250 in.	.34 in.	1.43 in.

40	.09375 in.	.51 in.	1.53 in.
58	.18750 in.	1.03 in.	1.70 in.

This comparison is intended to show that with the last figures the poppet valve has but half the valve area open at 58 degrees movement, while the piston valve gives within .05 inch of the full area. Or, it is put in this manner: That the number of degrees of movement required of the crankshaft to open the poppet valve .03125 inch will, with the piston valve, give approximately 6.5 times the opening.

In the drawing the motor is shown with the exhaust port open and the piston on the exhaust stroke. Beginning the suction stroke, the cam F moves the upper piston down until the intake port C is open, which simultaneously closes the exhaust port D. The point K on the valve is indicated by the point L on the cylinder wall. Near the end of the suction stroke and the beginning of the compression stroke the upper piston moves upward .25 inch, or only half the entire stroke, so that the rings A A are in the positions



Transverse and Sectional Views of the Carter Piston Valve Motor, Showing the Pistons, Valves, Overhead Camshaft and General Details of Construction.

shown by the dotted lines, closing both exhaust and intake ports, the piston remaining without change during the compression and explosion strokes.

Near the conclusion of the explosion stroke the upper piston again moves .25 inch upward, until the exhaust port is fully open, as is shown in the drawing. It is pointed out that the movement of the upper piston at no time exceeds .25 inch, while the total movement in either direction is .5 inch, the full movement taking place during the two revolutions of the motor. With a motor having stroke of six inches the movement of the working piston is 24 times that of the upper piston.

Claim is made that the motor is practically noiseless, that there is less vibration, that the valve opening is quicker, that it has greater economy, more power for piston displacement, greater piston speed, less heat is lost through the cooling by water, that carbon does not affect the valve, that adjusting or grinding valve is unnecessary, no working parts are exposed and engine is more easily handled by those not experienced, that the engine will endure more abuse and needs less repairs. The maker states that the economy is fully 20 per cent., that the power is from 20 to 25 per cent. more, and that the piston speed will be increased from 20 to 30 per cent.

As will be seen from the accompanying illustration the overhead camshaft is driven by silent chain that is steadied by an idler sprocket, the camshaft carrying a slightly smaller sprocket, the chain moving close to the cylinder wall. Two other silent chains are used, the one for driving the water pump and the other driving the magneto. All the chains are enclosed.

The engine is fitted with a starter that is mounted at the right side, the armature shaft being coupled with a transverse shaft that carries a worm that meshes with a gear mounted on the crankshaft. The starter is clamped to the engine case. All parts of the assembly are well protected and are very accessible.

The engine, while it has appearance that associates it with conventional designs, is protected by no less than 14 patents that have been granted within a year, and other applications are now pending. The maker, however, has so far perfected it that description of the detail has been made public and invitation is extended to engineers and others who may be interested to visit the factory and witness any tests that may be desired, or those that will have bearing on the claims for efficiency and economy. The purpose is to build these engines at the Pittsburg, Penn., factory, and this will be equipped with the special machinery and facilities necessary for production. The design has attracted much attention from engineers and the work that can be accomplished with the Carter motor will undoubtedly be closely observed by the engineering fraternity.

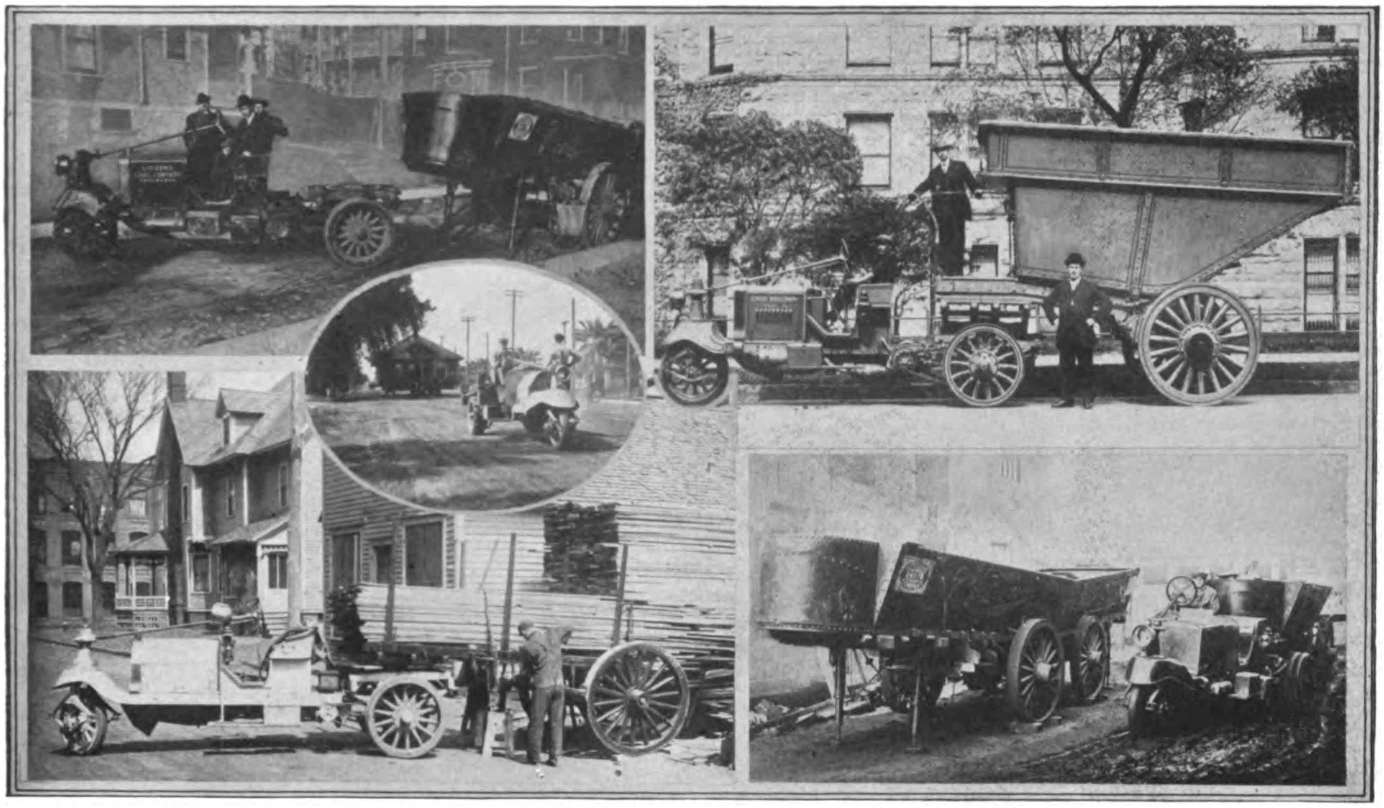
The Parcel Post Equipment Company has been organized to succeed the Grand Rapids Motor Truck Company, Grand Rapids, Mich., and has taken over the property of the latter concern, which failed. The new company is headed by Frank T. Hulswitt, E. Alfred Clements, Carroll F. Sweet, William F. McKnight and L. W. Coppock of Grand Rapids and John I. Taylor of Boston. The company will produce a 3000-pound delivery wagon similar in design to the Decatur, which was originally built, and will specialize a smaller machine which is expected to meet with the general requirements for parcel post delivery.

The new plant of the Four-Wheel Drive Auto Company, Clintonville, Wis., will be ready for occupancy about the middle of December, and with the equipment now being installed the production of the company will be materially increased.

ADAPTABILITY OF KNOX-MARTIN TRACTOR.

ONE of the strong points claimed for the Knox-Martin tractor, made by the Knox Automobile Company, Springfield, Mass., is its versatility. Coupled with this is its flexibility. In fact, it is maintained by its inventor, Charles H. Martin, that it is capable of supplanting the horse in every respect. Perhaps it were better to state that it is capable of supplanting a number of horses, for, of course, this is true when its pulling ability and speed are taken into consideration. Accompanying illustrations show some of the uses to which the Knox-Martin tractor has been put, and indicate its versatility and flexibility.

Very possibly, the desirability of securing a tractor of this nature was first demonstrated by the lumber trade. The earlier installations of motor vehicles with lumbermen established the fact that they could be used to advantage in competition with horses, but their economy and efficiency were found to be somewhat dependent upon the possibility of keeping them steadily employed. As a result of this situation, lumbermen began experimentation with a view to securing some method of eliminating delay in loading and unloading.



Illustrating the Versatility of Knox-Martin Tractor: Upper Left and Lower Right, in Coal Delivery; Upper Right, Hauling Ashes; Lower Left, in Lumber Work; Insert, Moving Houses.

Mr. Martin feels that he has entirely solved that problem. The use of his tractor permits one wagon to be loaded while another is on delivery. The front portion of the wagon, or trailer, is jacked up during the loading process, and when the tractor returns to the yard, it is released from its trailer, which is jacked up in a similar manner, and backed under the forward end of the loaded wagon. The time consumed in the operation is a negligible quantity.

The same method applies in the coal business, as may be noted from two of the accompanying illustrations. Here, however, another factor sometimes enters into the consideration. It often becomes necessary to back a load of coal into an alleyway or other position, so that it may be dumped into a side pocket. Another photograph reproduced herewith indicates the flexibility of the tractor in this respect.

The tractor virtually has two steering pivots, one consisting of the front wheel and the other, the king pin on the body, making it possible to turn the entire vehicle around in a very small radius and therefore avoid a large amount of manoeuvring necessary with horses. This is a feature the value of which will be understood in crowded traffic or in difficult places such as that presented.

The power of the Knox-Martin tractor can be appreciated when considering the view of what is regarded as one of the largest motor truck installations in the world. This vehicle is in use by a New York City contractor and is utilized for hauling ashes. Its capacity is rated at 15 tons, and yet vehicle and load are handled as readily and as easily as any of the smaller installations depicted.

If further evidence of the machine's versatility is needed, attention may be drawn to the insert in the group cut. This view was taken in Los Angeles, Cal., and illustrates one of the two jobs of like character ac-

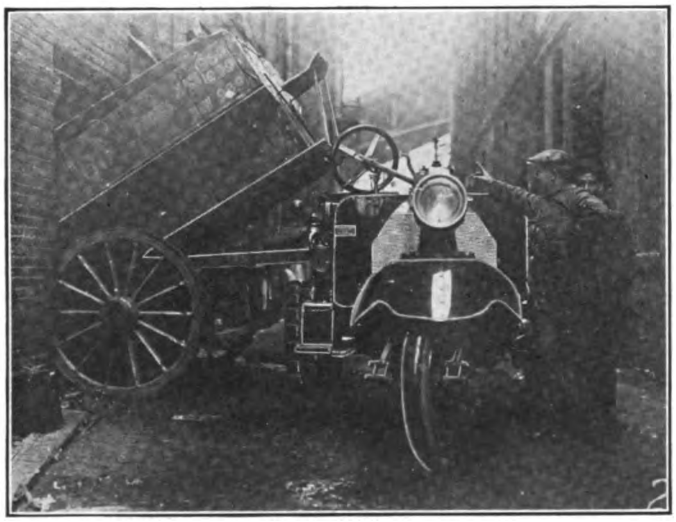
complished by the same Knox-Martin tractor between midnight and sunset of the same day. The two houses each weighed about 25 tons and were moved a distance approximating two miles.

Practically every reader is familiar with the old fashioned method of using a horse and winch for such work. Those who have watched the progress of a house through the public streets of a city under this arrangement are able to appreciate the comparative speed possibilities of the Knox-Martin tractor in this work, when it is remembered that the two houses were each moved about two miles in approximately 18 hours on the day in question.

UNIFORM MOTOR VEHICLE LAW.

Automobile Chamber of Commerce Favors Legislation Alike in All States.

The Automobile Chamber of Commerce is now on record as favorable to the enactment of legislation sim-



Indicating How the Knox-Martin Tractor May Be Backed into Difficult Places.

ilar to that in effect in Massachusetts and to the regulations recently promulgated in New York by the state highway commissioner; that is, that limit speed of machines weighing six tons or more to 12 miles an hour and of four tons or less than six to 15 miles an hour, the weight including the load. The directors of the chamber are opposed to overload and driving in excess of the speeds stated. The attitude of the directors is based on the belief that public opinion will be reasonable if there is understanding of the facts. To illustrate, the motor vehicle industry is quite as much interested in the preservation of roads as are the taxpayers themselves, or the owners of machines, and they are conducting a constant campaign for the development of highways, but they maintain that the passage of laws designed to protect the inadequate roads and bridges at the expense of the natural development of economical haulage by power vehicles, will only react to retard the really necessary improvement of the highways.

The directors in a statement emphasize that facts bear out the claim that animal traffic and passenger cars driven at high speed wear highways far more than trucks and wagons driven at slower speeds, and point to reports of state highway commissioners and to tests made by the United States government which show that motor vehicles driven up to 15 miles an hour were no more wearing than are animal vehicles. The directors object to all proposals to increase registration fees and maintain that excessive fees and unreasonable taxation is against public policy. It is maintained that the states would profit more by encouraging the use of motor trucks by continuing by a flat rate of $5 for all service machines.

In a statement the directors quote liberally from reports of different state commissioners and officials to strengthen their position, and hold that highways can be built and maintained so as to obtain satisfactory results at reasonable expense of construction and maintenance.

SEAMLESS STEEL TANKS.

Janney, Steinmetz & Co., Philadelphia, Penn., maker of pressed steel tanks, has begun, after a year of experimental work, the production of a seamless steel tank of rectangular section that is especially adapted to motor wagon and truck equipment. While suited for underslung installation of pleasure cars the tank has unusual qualities for wagon and truck use in that the former greatly economizes space and can be located where it will not take up space that might be desirable for loading purposes. The seamless tank insures against leakage of fuel and the accompanying danger and the production of the square form is regarded as a distinct advance in the art of metal drawing. These can be made in varying sizes, but are produced 13 inches square and from 30 to 36 inches length, and 12 by 14 inches and in different lengths between the two dimensions stated. These are furnished with or without Janney, Steinmetz fittings, which include brass gooseneck extension fillers, outlets with sediment cups, up-feed tubes for pressure installations and indicators to show the contents.

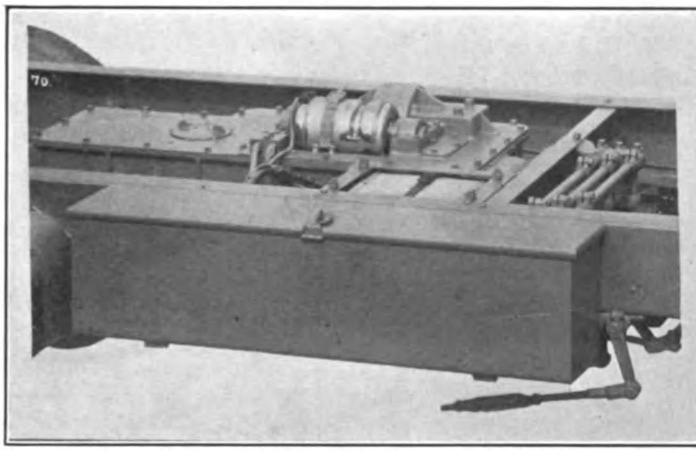
A four-ton KisselKar truck is used in hauling dairy products from the Edgewood farm at Pewaukee, Wis., to Milwaukee, to the depot of a corporation that supplies a considerable proportion of the people of Milwaukee with milk. Manager F. C. Kiekhefer says that the truck has given complete satisfaction in this work and in constant service hauling capacity loads on heavy grades on country roads under all conditions of weather has been serviceable from every point of view.

The promoters of the automobile show at Philadelphia, Penn., will have no exhibition of service wagons in connection with it, and the display will be for six days, beginning Jan. 10, 1914.

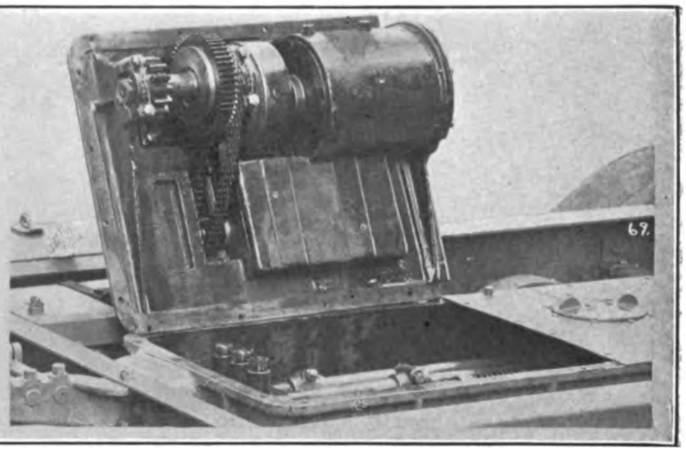
B. A. GRAMM'S TRUCK FOR 1914.

ANNOUNCEMENT is made by the Gramm-Bernstein Company, Lima, O., maker of B. A. Gramm's wagons and trucks, that it has planned to produce four sizes of machines during the coming year, and that these will be 2000 pounds, 4000 pounds, 7000 pounds and 10,000 pounds. Of these the 4000 and 7000-pound types have been built for more than a year, and these will be continued with several changes. The 2000-pound wagon was first produced several months ago, and this will be built without change from the specifications first made public. The details of the 10,000-pound truck have not as yet been made public. The claim is made by the maker that all of these vehicles have been designed with extreme care and with more than 13 years' experience in truck manufacture, the purpose being to produce what will best serve those who desire a machine of specified capacity.

The wagons and trucks are not all built to one design, for it is believed that what would be satisfactory for one type would not meet all the requirements of those who want smaller or larger vehicles, but all follow general principles of construction that have been proven with experience and have been accepted as being in accordance with good engineering. Exclusive qualities are to be found in each machine and these have been developed from practical knowledge and constant operation.



Electric Starter for B. A. Gramm's Trucks Installed on the Gearset Case.



Cover of Gearset Casing Lifted, Showing the Starting Motor and Its Drive.

The 2000-pound vehicle was described in a recent issue of the MOTOR TRUCK, and the specifications of the 10,000-pound machine have not as yet been stated definitely, while the construction of the 4000 and 7000-pound wagons is familiar to those who have knowledge of the industry. Of the last two machines mentioned it may be stated that they will continue to have the same low and sturdy construction, easy loading and easy handling being two of the qualities that were regarded as being specially advantageous and making for economy of operation. Both of these chassis were equipped with four-cylinder Continental motors, with bore of 4.5 inches and stroke of 5.5 inches, mounted on a spring-supported sub-frame, and this form of motor suspension has been found to work out in practise with extremely good results. This feature will be continued without change. The use of the dog clutch in the transmission gearset has been thoroughly tried and the endurance of the gears has proven the wisdom of this construction. The result from service has justified the use of this gearset in all the machines. The springs, of unusually large size, which are guaranteed for the life of the machine, will remain a feature of the design, as it is maintained that the quality and proportions of the springs have added materially to vehicle life and brought about minimized upkeep, this applying both to mechanism and to tires.

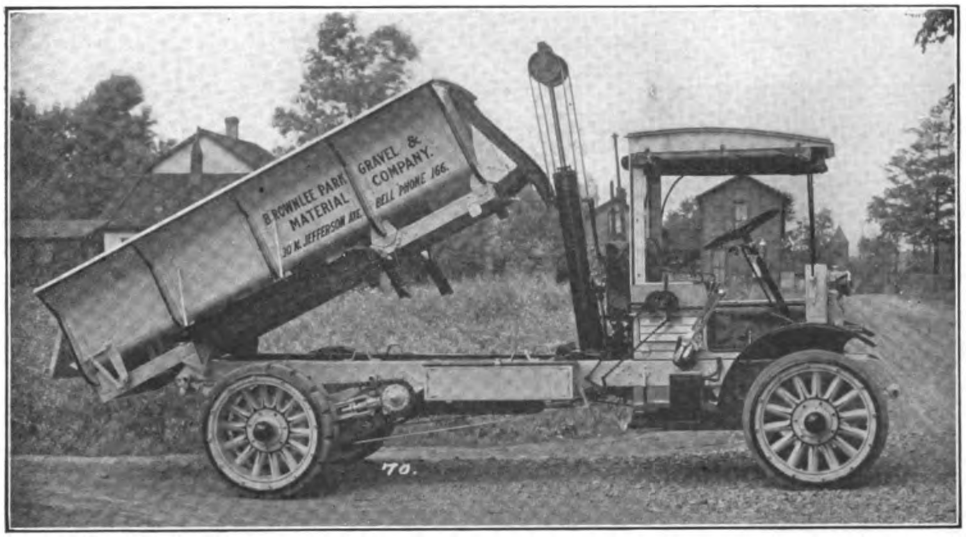
What is probably the most distinctive change has been made in the starting equipment, for this has been a feature that has attracted not a little attention to these machines. The original starting installation was, as is general with practically all vehicles so equipped, mounted on the engine case, and the motor was started by coupling it with the flywheel. After careful observation and experiment the starting motor and the generator have been installed on the cover of the transmission gearset, which location is believed to have a number of important advantages as compared with any other construction first used. The first consideration is the strain on the battery, which is by no means as severe as when the turning is done through the flywheel or the timing gears.

When the starting movement is made through the clutch, the clutch may first be allowed to slip and then gradually seats, so that the starting motor attains full speed before it is required to start the engine, and as the current demand upon the battery is materially lessened the strain upon the mechanism is decidedly reduced. With this form of installation at no time that the truck is moving is the generator idle, so that in descending long hills, where the engine is running slowly, the generator is always turning and the battery is kept fully charged.

No sliding gears are used in the mounting of the starter, all the gears being permanently in mesh. The

generator is driven by a silent chain. As will be noted from an accompanying illustration the motor and generator are mounted in the cover of the gearset case and the motor shaft carries a gear that is meshed with a pinion on the countershaft, the installation being so made that by removing the retaining bolts the entire cover and the motor and generator can be lifted out. The cover of the case forms a housing that protects the motor and generator, and it is very accessible. The starter gear and any one of the transmission dogs cannot be engaged at the same time. The starter is operated by the speed control lever. A year's experience has demonstrated that engine starters serve a very useful purpose and the claim is made by the maker that starters cannot be regarded as luxuries.

The company is now producing a dumping body that may be fitted to the two, 3.5 and five-ton trucks, the first of which was delivered to the Brownlee Park Gravel & Material Company, Battle Creek, Mich. The body is of steel and has a capacity of three cubic yards.



A 3.5-Ton B. A. Gramm's Truck Chassis Equipped with Hydraulic Hoist Dumping Body.

It is mounted on two heavy bearings at the rear of the chassis and the forward end is elevated by a hydraulic hoist driven off the main shaft. By this hoist the body may be raised to an elevation of 37 degrees and can be raised and lowered in 25 seconds. The hoisting mechanism is operated by the driver without leaving the seat, and the body may be stopped at any height, and the truck may be stopped or moving, so that the load may be distributed or discharged in a single place as desired. A safety stop limits the height of the lift and prevents damage if the power should be continued after the maximum elevation should be reached.

Claire L. Barnes, head of Claire L. Barnes & Co., with offices at Chicago, Detroit and Cleveland, will become the personal representative of John N. Willys on Jan. 1, and as such will have supervision of the Willys-Overland Company, the Garford Company and the Gramm Motor Truck Company with much, if not all, of the authority that was vested in George W. Bennett, recently deceased.

ROAD BUILDING ECONOMY.

Government Advises Minimum Grades of Lines of Least Resistance to Haulage.

The office of roads of the Department of Agriculture advises all concerned in highway building that a decided economy may be accomplished by increasing the average period of service of animals and motor vehicles, which will be automatically resultant from relocating old roads and building new so as to make the haulage along the lines of least resistance. The statement is made that to reduce the work for animals and to cause the least wear of motor vehicles and the least operating expense the highway that has the smallest grades is to be preferred, even when the distance is increased. Roads that are constructed with steep gradients, no matter if they are shorter, mean greater haulage cost because of the smaller loads and the lessened life of the animals and machines.

The farm owner may assume that roads built to this principle may take land that is valuable for crops or pasture and should not be sacrificed when other ways can be constructed that will be on land worth much less. The main question is whether the individual advantage from a road will offset the value of the property used for it, or the inconvenience of having the land divided. The officials maintain that a good road and traffic on it enhances the value of the abutting property, and the economy of a road with minimum grades is such that those using it could with reason give those who have provided the right of way an equivalent in equally good land in compensation for the property sacrificed for the common welfare.

The office is educating the people to the economic value of good roads, even at the sacrifice of better land in obtaining them. Investigation demonstrates that the building of roads has often been with reference to the preservation of farm lines rather than from scientific or economic consideration. Evidence appears to be that haulage can be increased materially and at lessened expense merely from changes of grade, while relocation of roads is with no increase of length in some cases and of but little in others.

This attention has been directed toward the development of the country roads, because on them haulage is invariably expensive and improvement can only be made according to the resources of the communities in which they are.

The Standard Truck Company of Cleveland, O., has increased its capital stock from $5000 to $50.000.

TRAILERS FOR HIGHWAY HAULAGE.

Type of Vehicle Designed for Economical Service with Motor Trucks, Developed by Troy Wagon Works Company After Much Careful Experimentation.

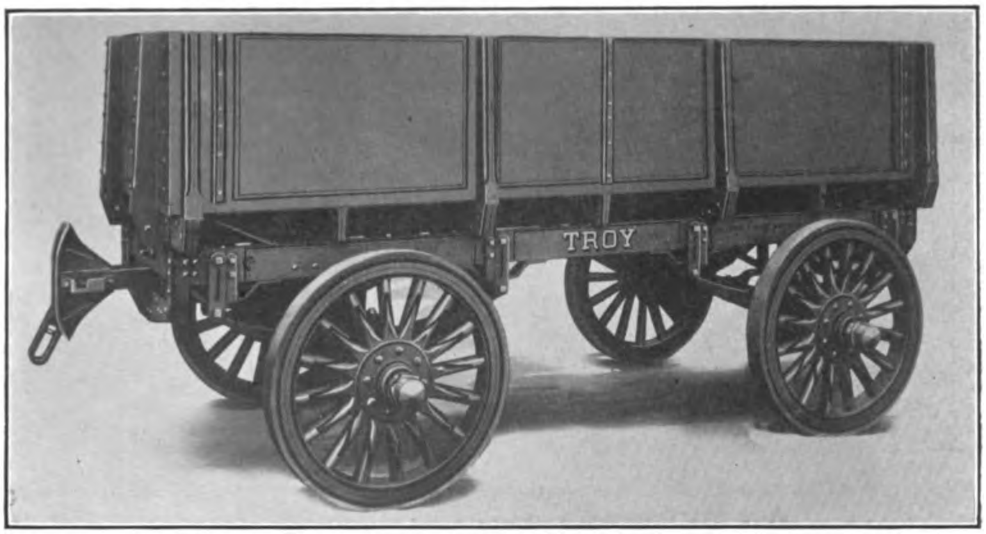
TRANSPORTATION by highway traction engine is no experiment. This form of haulage is very common in Europe, especially in England, where thousands of such engines are in service. In America construction companies have utilized steam road locomotives or even road rollers for the haulage of material, but often horse wagons have been adapted. Equipment that might be practical on smooth surfaces becomes impractical where the roads are rough or the ground is broken, and because of the strains peculiar to drawing a loaded vehicle those constructed for animal service have been found to lack endurance.

In theory haulage by trailers affords economy by increasing the load, but the speed of the train of vehicles is decreased as the number is increased. The speed is necessarily limited under the most favorable conditions, and six miles an hour may be regarded as maximum. Loaded, the probability is that this rate would not often be reached. The motor truck can be driven at faster speed than the animal wagon and the capacity is greater. Experience has taught that the largest measure of economy is in neither high speed nor extreme loads, but the best results have been obtained through keeping the machine in operation as much of the time as is possible.

Experiments have determined that the most practical use of trailers is not in large trains, but in having such a number that there need be no delay in the haulage of the tractor, and the loading and unloading can go on while the machine is in operation. That is to say, that where the distance is not too great six trailers and a tractor, for instance, can be worked very advantageously by having two at the place of loading, two at the place of unloading, and two on the road, at practically any given time.

Considering the matter of road trains, as the combination of tractor and trailers should be known, the limitation of the traction engine is evident. It can be used only for haulage of trailers, and cannot be worked productively on small jobs, in traffic or in conditions where speed is a material factor. In England and Continental Europe the traction engines are generally used on good highways and can haul large loads long distances, in which work they have been found to be very profitable when the cost of carriage is compared with the expense for railroad freightage. But unless there is practically constant work for a traction engine it cannot be regarded as a good investment. For this reason the use of motor trucks with trailers is believed to be the logical equipment for heavy haulage, for this will afford every quality desired, and the truck may be worked continually. The trailers are equipment that ought to endure for years, for the mere haulage of loads at comparatively slow speeds will bring but little, if any, deterioration.

The use of trailers has not been studied by many. Several builders of traction engines have produced trailers, but these are not of a type that can be well utilized with motor trucks. The Troy Wagon Works Company, Troy, O., after experiments extending over a considerable length of time, has begun the manufacture of trailers that have been carefully designed and developed with the purpose of obtaining the greatest utility and economy, and after trials had determined the practicability of these conveyances. The company for eight years has built trailers for use with traction engines, and for more than two years worked on the trailer proposed for the motor truck before the design was regarded as meeting with all requirements.



The Troy Trailer Chassis Equipped with a Body Having a Capacity of Five Tons, an Equipment Designed for Use with Motor Trucks.

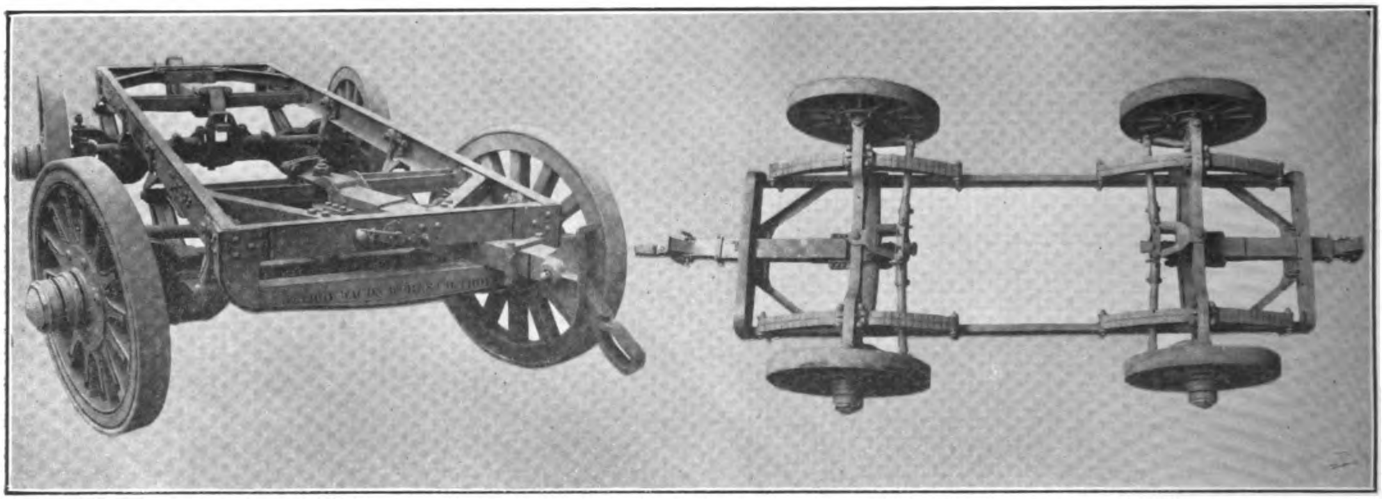
The trailer train to be practical must be controlled at all times, must be backed straight and in different curves, and the units constructed to require the smallest degree of power for haulage. Experiments justified the conclusion that the average motor truck loaded to rated capacity develops a drawbar pull equal to about half its rated load. That is, a three-ton truck in the condition stated will develop a drawbar pull of about 3000 pounds, but a team of horses will develop a maximum sustained drawbar pull equal to about 25 per cent. of their weight, or 750 pounds of drawbar pull for

a team of horses the weight of which is 3000 pounds.

Tests of different kinds established that on brick paving 50 pounds drawbar pull would draw a ton weight on level surface, but on hard country road 150 pounds drawbar pull was required for the same work. With these conclusions as a basis further experiments showed that on average roads and on average grades an average drawbar pull of 250 pounds for each ton of load carried was necessary for average work, and that a three-ton truck could be expected to draw 10 tons in addition to the load on the truck, so that the drawbar pull could be estimated as equalling that of at least three 3000-pound teams of horses. For the better demonstration of the statement curves have been plotted that show different conditions of road and the results accomplished at varying speeds. This chart will show that the estimate stated is much in excess of the charted requirements, but this apparent discrepancy is an allowance for possible exigencies not experienced in the tests. With these facts as a foundation the trailer was developed.

Having established the power that could be expected with a motor truck, the next proposition was to determine whether with trailers a truck could haul a ton of material at lower cost than without trailers, and what form of trailer could best be used. Careful tests having proven that the truck could be used economically with trailers, the design of the trailer was worked out. Five tons capacity was fixed as the limit for a trailer, and to permit turning in short radius, an imperative quality, a short wheelbase was necessary. Other qualities required were that the trailer must follow and be guided by the tractor, be either pulled or pushed equally well, that the drawbar should be attached to a flexible frame, that the wheels and axles should be flexibly connected to the trailer frame, that the drawbars should be resilient, that the drawbars should be constructed to minimize the shock of starting and stopping, that the trailers should be coupled and uncoupled quickly, that the trailers be so constructed as to be used with teams or other power in the event of necessity, that the construction be enduring, that the loss from friction be minimized, and that sufficient means for lubrication be provided.

If note be made of the illustrations the reader will learn that the Troy trailer is a chassis on which differing types of body may be mounted. The description will apply to the chassis only. The frame is mounted on semi-elliptic springs and the axles and connections with the drawbars are alike. The frame is a steel channel section construction with a cross member above each axle, with diagonals from each end member from either side of the centre to the side members. The frame end members are assembled with upper and lower sections riveted to castings, there being a slot or opening the entire length, or width of the chassis. Just back of the frame ends are the outside spring shackles, which are suspended from a heavy single bolt, and a similar shackle is located 48 inches along the frame. On these shackles the spring, 48 inches length and 3.5 inches width, is carried. The axles are heavy steel forgings, I section, but widened at the ends with openings through the axle for the spring, the seats being at the bottom of the openings.



Troy Trailer Chassis with Drawbar Swung to Afford the Shortest Turning Radius.

Bottom View of Troy Trailer Chassis, Showing the Construction of the Drawbar Control.

The ends of the axles are yoked and into these are set the pivots that carry the wheel spindles. These pivots will swing a radius of 180 degrees without the wheels. On the spindles are the heavy wooden, 36 inches diameter wheels, having 14 spokes three inches width, and fitted with steel tires four inches width. The wheels and pivots are carried on roller bearings.

From each pivot an arm extends, that is yoked at the end, and into the yokes are fitted the tiebars, these being short sections that are fitted into a rectangular member with a yoke at either side. A yoke pivoted from the axle centre supports this member and permits it to swing from side to side as the tiebar is drawn. This is necessary as in this construction the tiebars are in three sections, and are above the springs. The frame cross members above the axles support the inside ends of the drawbars, which are yoked so that there is a yoke arm above and below each member. The drawbar yokes are pivoted on the cross members. Bolted to the yoke arms are tongues that are extended into

the slot in the rectangular member in the centre of each tiebar. The drawbar is thus made a lever with the fulcrum at the frame cross member, and swinging it will turn the wheels through the tiebar and pivot arms. The angle is limited by the slide in the frame end members in which the drawbars swing or slide. Each drawbar may be locked in a centre position, and when hauled in trains the forward drawbar is free and the rear drawbar locked, and the trailers will follow in the exact radius of the turn made by the tractor. When backing the forward drawbar is locked and the rear drawbar is free. That is, when moving forward the effect is precisely the same as with any vehicle with a fixed rear axle. When backing the result is as though a fixed rear axle vehicle were turned end for end. Backing is accomplished by a man swinging the rear drawbar of the rear trailer to the desired angle.

The drawbar heads are steel castings that, when installed, have a vertical slot or opening in which the coupling link may be raised or lowered an angle of 45 degrees to the direct line of draft. These heads are so formed that they will contact and will not "ride" each other because of inequalities in the road surfaces. The drawbar is a rectangular tube of heavy section metal into which the shank of the drawhead is telescoped. This contains a helical spring that will compress when 200 pounds pressure is reached, and this will resist compression up to 2000 pounds pressure, when it will be fully compressed. This spring is so installed that the compression resistance is equally effective when the trailer is drawn or pushed. This affords a degree of resiliency that minimizes the strain upon the trailer and the tractor or truck drawing it.

The drawbar affords resiliency between units in the trailer train. The spring shackles are so designed that when at the lowest point stops prevent reflection, but when deflected the springs will swing backward until the stops on the front or drawing ends of the springs are seated, when the rear or free ends will have movement. All the drawing or pushing strain is exerted upon the springs, and the shocks of road obstructions are absorbed by them. The tongues of the drawbars have a vertical movement in the rectangular members of the tiebars corresponding to the deflection and reflection of the springs, and there is no resistance and no strain. The coupling links are so constructed that they are pivoted in the centres so as to have a sidewise movement from the pivot, this relieving strain when hauling, but when backing in multiples or holding on descending grades the flexible joints of the links are within the drawheads and there is a rigid connection.

The specifications of the trailer, which has a maximum capacity of five tons, are: Weight of chassis, 3330 pounds; length of chassis frame, 142 inches; width of chassis frame, 41.5 inches; tread (from centre to centre of tires), 64.5 inches; wheelbase, 81 inches; length overall, 173 inches; width overall, 84.5 inches; height of top of frame above ground, 34.5 inches; road clearance, 17 inches; wheel diameter, 36 inches; tire width, four inches; length between steering arms, 58 inches; length of springs, 48 inches; spring width, 3.5 inches; diameter of wheel spindle, 2.875 inches.

PRACTICAL PROMOTION.

Electric Vehicle Association Aiding Petitioner for New York 'Bus Franchise.

The value of organization and the possibilities for directing endeavors along practical lines is demonstrated by the activities of the Electric Vehicle Association of America, which is aiding the People's Five-Cent 'Bus Company in a campaign in New York City to obtain a franchise to operate 20 lines of motor omnibuses in different parts of the municipality. The petition is pending before the board of estimate, and the purpose of the company is to afford service with electric vehicles for sections which are not now well served by transportation companies.

The company purposes to divide the city into zones, the fare in each to be five cents, but passengers going the length of the city will pay two fares. The plan is regarded by the promoters as having material advantages for the people, and the claim is made that as most of the 'bus rides would be comparatively short distances the zones and the five-cent fare will give cheaper transportation and extremely efficient service.

The petition has been opposed by street railways and existing omnibus lines, a statement being made in behalf of the opposition that any increase of motor trucks throughout the city would endanger the lives of pedestrians. President Frank W. Smith of the Electric Vehicle Association, representing that organization at a hearing, controverted such a contention by emphasizing the simplicity of control and ease of operation of electric machines. He stated that within New York City were 500 enthusiastic owners of electric trucks, using 2100 vehicles, and that these owners would willingly testify before the board of estimate as to the great safety of their machines, or, if the board elected, his association would gather the facts and present a brief.

At this same meeting Miller Reese Hutchison represented Thomas A. Edison, who was confined home by a cold, and read this letter from Mr. Edison: "I believe that for traction in cities the electric motor will displace all other motors. Already it has displaced steam on street cars, elevated railways and subways. It drives all of the elevators and most of the machinery in the city. If 'buses are desirable for intercity traffic, the electric is the only practical one. It is noiseless, has half the destructive effect of a gasoline engine, and can be stopped quicker than the gasoline vehicle, with the added economic value of much cheaper operation".

The International Motor Company has sold the building at 532-40 Atlantic avenue, Brooklyn, N. Y., formerly occupied by Mack Bros. Motor Company.

ADVERTISING RATES.
Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Postoffice at Pawtucket, R. I., under the Act of March 3rd, 1879.

NIGHT HAULAGE IN CITIES.

The proposal that congestion of highway vehicle traffic in cities of considerable proportions be relieved by doing more or less of the haulage at night, appears to be the only logical solution of a problem that is becoming more and more pronounced. There is no question that street widening is too costly to be seriously considered, and the loss from the idle time of men and vehicles is such that business organizations must seek relief. Traffic regulation has accomplished a great deal, but the result has been chiefly in making the streets safer for pedestrians.

Beginning early in the morning, the traffic usually increases until its height is reached late in the afternoon, and from 6 in the evening until 4:30 the same thoroughfares are practically deserted. If haulage were distributed over the 24 hours of the day there would be a decided increase of productive time, and there would be comparatively little loss. This could apply to wholesale establishments, to railroad terminals and piers, to delivery of coal to manufactories, shops and buildings, and to transfers of freight and baggage, and would mean adjustment of hours of work more than anything else.

Night haulage would mean greater safety for the public, for a considerable part of the time there would not be more than a small per cent. of the pedestrians in the streets, while the diminution of traffic would reduce the dangers that now exist by day. Not only this, the use of the highways continuously would obviate many of the conditions that have brought about regulations that are regarded as hardships.

"SERVICE" AND "MAINTENANCE".

The manufacturers of motor service vehicles should establish precisely what is meant by the term "service". The word as it is generally used is decidedly indefinite, and because of this fact the purchaser of a machine has no knowledge of the responsibilities of the manufacturer, the agent or himself. The maker as a rule makes a guarantee against defective material or faulty workmanship within a stated period. The salesman makes promises and the agent assumes obligations because he considers it wise to do so, and the buyer may be justified in expecting supervision, advice, and whatever he can secure beyond the assurances of the guarantee, including damage resulting from his own ill judgment or the incompetency or neglect of the driver.

The experience has been that many men expect maintenance as well as service, and the company or agent makes concessions that are not warranted simply to prevent discontent of the owner and avoid criticism that is assumed would be adverse to future business. The buyer of a motor truck will permit abuse and neglect and then complain that he has been made a victim in purchasing, and will seldom admit that his own judgment was at fault. Were there a rigid definition of service, and this lived up to by manufacturers and agents, and the responsibilities actually placed, there would be far less criticism and dissatisfaction.

TRUCK OWNERS' ORGANIZATIONS.

That owners of service wagons and trucks have failed to organize for the promotion of their interests is not strange when one realizes that there has been no general inclination of those concerned in highway transportation to unify in organizations that might be productive of material benefit. Master teamers have formed associations in some cities, but these are the exception and not the rule. The principal purpose to be obtained is united action in the event of controversy with labor. There are very large possibilities, however, for owners of vehicles who wish to apply economic methods and improve their service, and there can be no better manner of acquiring knowledge than by exchange of experience and by adopting uniform policies and means of meeting conditions that may be met with.

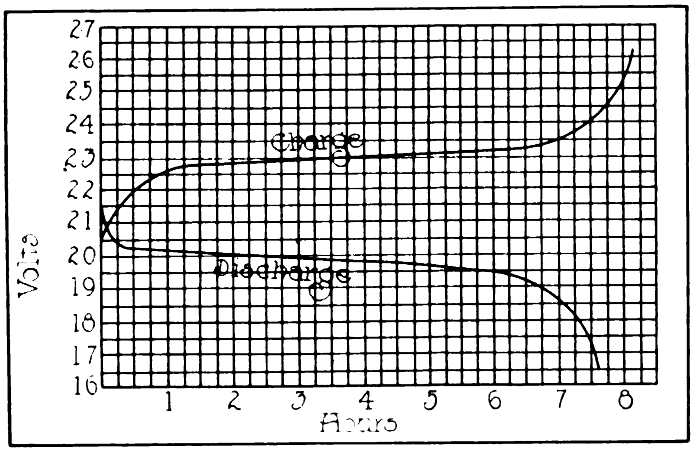
There are innumerable problems that could be practically dealt with, and the influence of an organization could be exerted with decided results where the endeavors of one or several would fail. As the use of service vehicles increases legislation will be an exceedingly important subject, and as legislators as a rule have excellent machinery and carefully developed resources, the futility of opposing them without organization is apparent.

ELECTRIC VEHICLE PRACTISE.

Tests of Electrolyte to Determine Metallic and Other Impurities---Influence of Temperature on Cell Capacity---Conditions Affecting Battery Efficiency---Internal Resistance and Local Action and the Results of Self-Discharge.

By William W. Scott.

WHEN this can be done, the electrolyte, before it is placed in the cells, should be tested for impurities, and it is good practise to test it from time to



Curves Showing the Characteristics of Voltage Increase and Decrease with Charging and Discharging.

time during the period it is used. The knowledge that the electrolyte is pure is assurance that there will be satisfactory results from the cells and minimum deterioration. While the average batteryman may not be a chemist, he can detect conditions that will cause destructive action. The tests should be made for the traces of metals or chlorine in their order of importance, which can be accepted as follows:

When an electrolyte is placed in a cell containing a regular element and the cell is on open circuit, if gassing should continue for a considerabe length of time one may safely assume platinum is present. The slightest trace of platinum will cause a discharge from the negative plates. If this test justifies the belief that platinum is in the acid a more complete examination can be made.

The presence of iron can be ascertained by neutralizing a solution of two parts acid and one part water with ammonia or caustic potash in solution, which may be boiled with a volume of hydrogen peroxide or nitric acid equal to about one-thirtieth of the specimen of electrolyte. The boiling will transform the iron into a ferric state, and if a sample be placed in a test tube and caustic potash solution or ammonia be added so as to make the sample alkaline, a brownish red precipitate will form if there is any considerable volume of iron present. A more delicate test can be made by adding several drops of prussiate of potassium to a sample of the boiled electrolyte, which will cause it to become red in color.

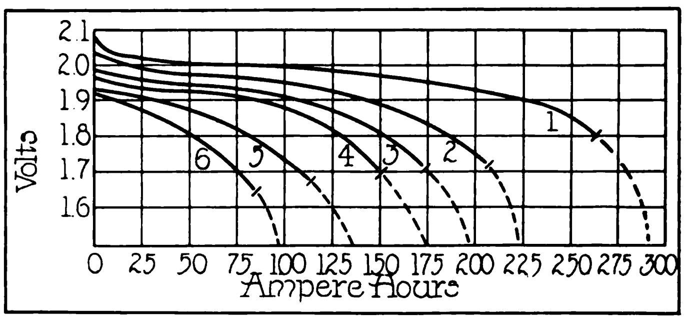
A satisfactory test for chlorine is made by preparing a solution by dissolving 20 grams of nitrate of silver in 1000 cubic centimeters of distilled water. A few drops of this solution may be dropped into a specimen of the electrolyte, and if chlorine is present, as chlorides, the electrolyte will change to white from the precipitation of silver chloride. If the precipitate is milky, but a small volume of chlorides is in the electrolyte. If it becomes curdy the volume of chlorides is much larger.

Several tests may be made for nitrates, but the best is by placing some chemically pure copper filings in a test tube and partly filling it with the electrolyte that has been tested and found free from chlorides. The tube should be corked, and through the cork should be introduced the end of an S shaped glass tube. One turn of the tube will form a trap, and this should be filled with a solution of ferrous sulphate. If the tube is heated by a bunsen burner the nitrate vapor will be forced to pass through the solution of ferrous sulphate and this, absorbing the nitrates, will be changed to a very dark brown color.

The addition of a solution of ammonia to electrolyte will, should there be copper present, cause a bluish-white precipitate to form, but should an excess of ammonia be added and the solution become alkaline, the precipitate will be obliterated and the fluid will become dark blue in color. This test will show .002 per cent. copper. Other tests may be used, but this will be sufficient.

If lime water be added to electrolyte a black precipitate will form if mercury is present, and the addition of a solution of potassium iodide will cause an olive green precipitation.

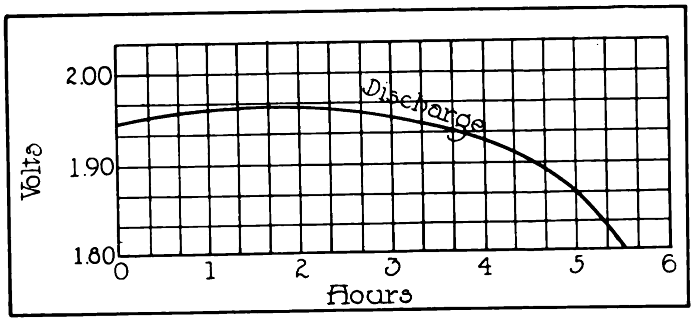
A very good test for arsenic can be made by taking a specimen of acid and reducing it by the addition of



Curves Illustrating the Voltages and Duration of Discharge at Varying Rates.

about 80 per cent. of distilled water, and to this solution adding about a tenth of its volume of concentrated hydrochloric acid. In this a tiny coil of copper wire,

polished to brightness, should be deposited, and the solution boiled for 15 minutes. The copper will become brown or black if arsenic is in the solution.



Curve Showing the Slight Rise of Voltage at Beginning of Discharge After a Considerable Period of Rest.

If acetic acid is suspected the electrolyte should be neutralized with ammonia and ferric chloride added. Should the solution become red and the addition of hydrochloric acid bleach it, an appreciable quantity of acetic acid is present.

To determine the existence of organic matter an analysis is preferable, but it is possible to reach a practical result by boiling electrolyte in a beaker to a point where it is so concentrated that white fumes will be given off by the acid. The discoloration of the fluid will indicate that there is organic matter in sufficient quantity to justify greater attention.

In making the tests care must be observed to prevent the introduction of impure matter with the water or the chemicals used. If the solution proves to be free from platinum, iron, chlorine and nitrates, the electrolyte may be assumed to be safe for use, but a better safeguard is to make all and be absolutely certain.

The statement has been made that in the designing of a cell the volume of electrolyte is kept as small as is practical and good results can be obtained, because of the desire to minimize weight, but the greater the volume the better, as a rule, is the efficiency of the cell.

It has also been stated that in the computations of engineering data the temperature is generally taken as 60 degrees Fahrenheit, but many engineers vary from this and having corrected their tabulations for density at higher temperatures follow their own formulae. These tabulations serve a very useful purpose, as they can be made to cover temperatures from 32 to 120 degrees, and efficiency of the electrolyte can be ascertained at a glance. In some instances curves are plotted that cover both temperature and density.

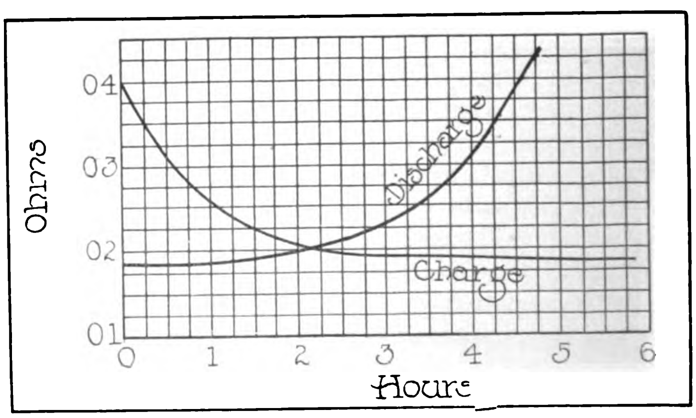
As a base for computations a temperature of 60 degrees may be taken, and as with this the following densities can be assumed with acids of 1.835 and 1.842 specific gravities, the range showing the proportions of acid by weight:

Specific Gravity	Weight in Pounds a Cubic Foot	Per Cent. of 1.835 Acid	Pounds of 1.835 Acid in One Cubic Foot	Per Cent. 1.842 Acid
1.151	71.79	22.00	15.79	20.570
1.160	72.35	23.25	16.82	21.739
1.169	72.91	24.50	17.86	22.907
1.179	73.53	26.00	19.12	24.310
1.188	74.10	27.25	20.19	25.479
1.198	74.72	28.50	21.30	26.647
1.208	75.34	30.00	22.60	28.050
1.218	75.97	31.25	23.74	29.219
1.229	76.65	32.75	25.10	30.621
1.239	77.28	34.00	26.28	31.790
1.250	77.96	35.50	27.68	33.192
1.261	78.65	37.00	29.10	34.595
1.272	79.33	38.37	30.44	35.876
1.283	80.02	39.75	31.81	37.166
1.295	80.77	41.25	33.32	38.569
1.306	81.46	42.62	34.72	39.850
1.318	82.20	44.00	36.17	41.140

It should be interpolated that, while 1.842 is the specific gravity of sulphuric acid and is the standard for all electro-chemical determinations, 1.835 is the specific gravity of commercial sulphuric acid, and this is the standard that may be used in mixing electrolyte.

Manufacturers of batteries usually have their own standards of electrolyte mixing, and an example of this may be stated where the normal maximum density of a battery is fixed as 1.285 at 85 degrees Fahrenheit, but when the cells are shipped they have a specific gravity of 1300, which is the highest that is permissible. The charging voltage will be less as the temperature of the electrolyte rises, and this has been proven to be as much as .18 volt by the increase of the temperature from 57 to 113 Fahrenheit. The greatest loss (.12 volt) was between 57 and 86 Fahrenheit temperature, but this loss cannot be sufficiently established to graduate it with accuracy. The discharging voltage will increase with the increase of temperature. Careful observations have proven that the amperehour and watt efficiencies decrease with the increase of temperatures. The considerable increase of temperature has the effect of increasing the porosity of the active material and through the greater activity of the electrolyte the discharge capacity of a cell is somewhat enhanced. The manufacturers and their engineers generally agree that the temperature of a cell should not be permitted to rise above 110 Fahrenheit. With the increase of temperature the resistance of the cell decreases and the local action will increase.

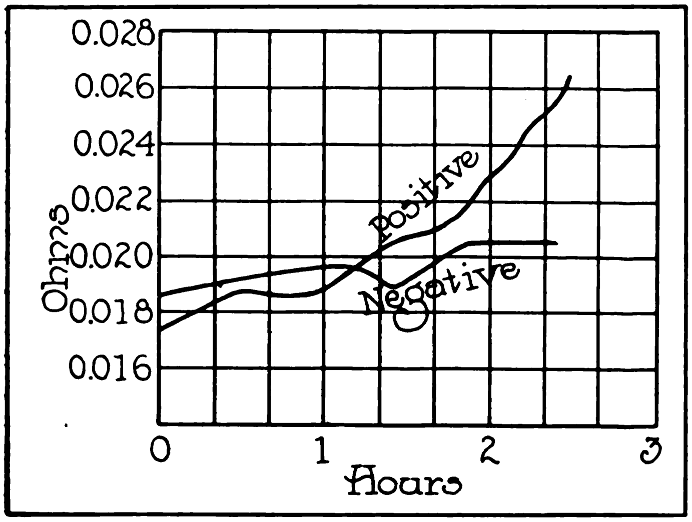
The efficiency of the lead-acid cell is dependent upon a number of conditions, which include the charging rate, the discharging rate, the internal resistance,



Curve Demonstrating the Decrease and Increase of Internal Resistance of a Cell with Charging and Discharging.

the volume, density and diffusion of the electrolyte; the period of time between the end of discharging and beginning of charging, the absence of local action and

the temperature, and the result may be expressed in the ratio of the useful current discharged, the standard being the current required for charging. The ratio



The Variance of Resistance Developed with Positive and Negative Plates During Discharge of a Cell.

of ampere-hours discharged to ampere-hours charged indicates the ampere-hour efficiency, and in a similar manner the ratio of watt-hour efficiency may be expressed.

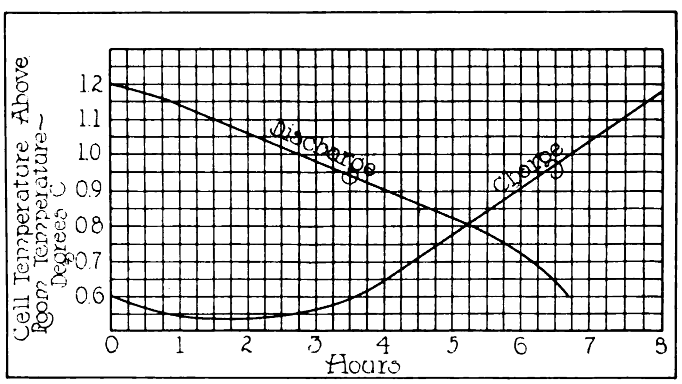
The reduction of efficiency of a cell from losses of energy may be the result of resistance loss, internal discharge from local action, the evolution of gas at the conclusion of discharge, and irreversible chemical reactions. In consideration of these, resistance may be first discussed. So far as the cell is concerned this loss during discharge may vary from two per cent. at low rates to five per cent. at high rates, but is not often in excess of this figure. The internal resistance of a cell will result from the resistance of the metal forming the frames of the plates, the resistance of the active materials of the plates, the resistance of the electrolyte saturating the active material, and the resistance of the electrolyte, and of these the most important is the resistance of the active material and the electrolyte contained in the pores of the plates. The others are of minor consequence. The statement as to loss during discharge is based on the supposition that the cell is in good condition.

As has been stated, the variation of temperature will influence the resistance, there being a gradual decrease as the temperature increases, from the seemingly greater porosity of the active material and the better diffusion. The results of charge and discharge should be remembered for a moment, and it is evident that in charging, assuming that a reasonable condition of sulphation is to be dealt with, the resistance will be greatest at the beginning. Careful observation has established that this resistance will diminish gradually until a minimum is reached, and from this point on until the end of the charge there will be but very little change, though there will be a slight diminution. In discharging the resistance will be least at the beginning and it will increase as the sulphation progresses, until the cell is completely discharged, or at least so long as discharge continues. The best authorities maintain that when a cell is charged the resistance is practically all from the electrolyte, but in discharging the resistance is dependent upon the degree of sulphation, and it may be from four to five times as much as at the maximum charge. The greatest change is in the positive plates, in which the resistance is increased constantly, but the increase in the negative plates is slight in comparison. As the rate of discharge is increased the internal resistance of the positive plate becomes more pronounced than when the rate was low. This may be attributed to the density of the acid in the pores of the active material, the degree of the combination of lead sulphate with the lead peroxide, the thickness of the formation of lead sulphate on the surface of the plates, and the reduction of the acid density. With high discharge rate the conditions which cause greater internal resistance are the more quickly reached and they are carried to a greater degree than with a low rate.

In charging, if the form of the plates is such that there will be accumulation of gas on them, there will be increase of internal resistance, but in addition to the ohmic resistance the effects of polarization, in combination with the resistance, is to increase the potential when charging and decrease it when discharging.

Loss of energy from internal discharge or local action may result abnormally from current that flows from one part of a plate to another from a difference in potential that may exist in different parts of the same plate, from impurities that are in the cell, while normal internal discharge may result in a cell in which there are no impurities, but will take place only at the end of a discharging period. The normal internal discharge is usually of little importance and is seldom of extended duration. As generally applied in battery engineering the term "local action" refers to more or less continuous discharge, which must result in sulphation of the plates and a consequent deterioration and reduction in capacity.

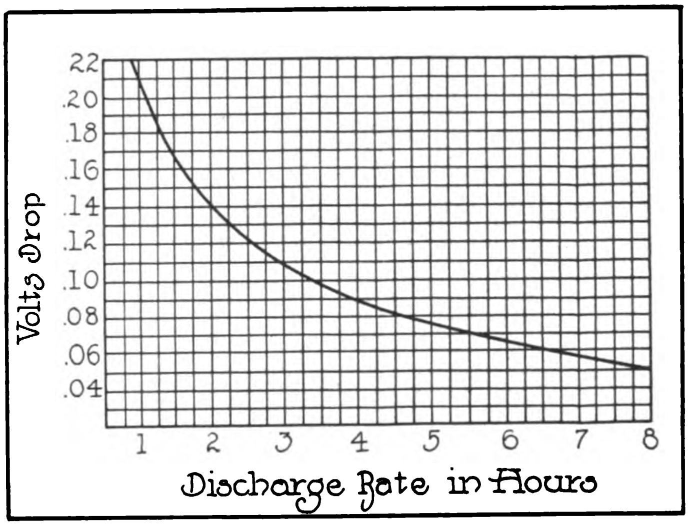
The reader will recall the statement that when an element is placed in electrolyte, and the cell be not



Cell Temperature Variation During Charging and Discharging in a Room with a Constant Temperature.

charged, sulphation will take place. The reason is that the sulphuric acid will transform the surface, or cover it with a formation of lead sulphate that is

similar in effect to a plating or sheet of insulating material, and the effect of the charging is to reduce the sulphation and increase the density of the electrolyte.



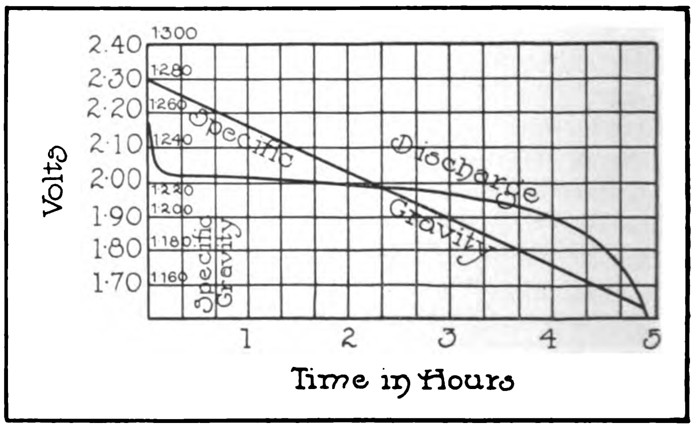
Decrease of Cell Voltage Is Dependent upon the Rate of Discharge, as Illustrated by This Curve.

Beginning with the discharge this sulphation goes on until the end of the function. Concentration of the acid and the increase of temperature will intensify local action. High electrolyte density will cause sulphation of the negative plates, for these electrodes are more easily affected than are the positive, as the sponge lead is necessarily cellular in structure and the metal has a greater electro-positive value. A fully charged negative plate removed from the cell and exposed to the atmosphere will heat and harden through rapid oxidization.

The negative plate can usually be assumed to be free from impurities in the manufacture or formation, but there is a possibility of acids or their salts, used in the production of the positive plates, not having been entirely eliminated and becoming active when the plates are submerged in electrolyte. The result of the presence of these substances is the increase of cell capacity, but the plate will rapidly deteriorate. A reasonably safe assumption is, should the capacity of the cell increase after it has been charged and discharged 30 times or more, that the cause is an acid or salt of an acid that, in combination with the electrolyte, is attacking the positive plates. When conditions are normal the chemical effect of the electrolyte on the lead peroxide of the positive plates is not a matter of importance. It is possible, however, for superoxides to be formed by charging that will be of consequence, for the peroxide will be reduced to a lower oxide.

The elimination of lead sulphate from the pores of the active material of a pasted or Faure plate and the permeation of these pores by the electrolyte, may cause a couple between the active material and the frame of the plate, and there is greater activity where the frame is of pure lead. This result is not usually of a character to be of importance. If such a condition existed it would continue until there was a sufficient formation of lead sulphate to protect the frame.

Particles of metal in the electrolyte, introduced with acid, can bring about local discharge on the positive plates if the metals are easily oxidized. When such impurities exist these carry oxygen from the positive to the negative plate and thus cause the charge to be transferred, the result being the eventual internal discharge of both plates. This condition obtains with all metals that are not precipitated on the positive plates. Deposits of metallic particles on the negative plate results in the two metals forming a tiny cell that is in short circuit. In the event that the metallic particle has greater electro-positive strength than the sponge lead of the negative plate, a current will flow from it through the electrolyte to the sponge lead, and the result is that hydrogen is released from the negative plate and it becomes more strongly charged. If the metallic particle has greater electro-negative strength than the negative plate the current will flow from the plate through the electrolyte to the foreign metal and hydrogen is released at the metal and oxygen is released at the plate. The result is the formation of lead sulphate and the negative plate is consequently discharged. In other words, when an active couple is established on the negative plate the result may be charging or discharging, the conditions necessary to bring about this result being the actual contact of the metals and a difference of potential that will cause decomposition of the electrolyte, as well as the influence of the electrolyte upon both the foreign metal and the plate. The influence of metals varies, that of platinum being the greatest, and the statement of an undoubted authority is that as minute a particle as one one-millionth will cause internal discharge. The elements most to be feared besides platinum are iron, copper, arsenic, manganese, antimony and mercury. When a plate has been discharged by platinum in the electrolyte its efficiency can only be restored by reversal of the current, but other metals deposited on the negative plates may become covered with deposits of sponge lead and in time lose their harmful influence. A very good indication of the presence of a foreign metal in a cell is the liberation of hydrogen gas from



Decrease of the Specific Gravity of a Cell with the Discharge.

the negative plates when the cell is on open circuit.

Hydrochloric acid in a cell will form chloride of lead, which is later transformed to lead sulphate, and

results in discharge of the positive plates, and the transformation of the lead chloride releases the acid, which is free to renew its injurious influence and repeat the process. A sufficient volume of this acid will cause sulphation of the sponge lead and a similar result as with the negative plates, but the chemical action of the cell and the action of the electrolyte will neutralize the acid, if but a very small proportion exists. Arsenic will have a discharging influence upon the negative plates for a short time if in a cell, but will not affect the positive plates. The metal is either precipitated or it is liberated as arsenated hydrogen. Nitric acid will cause corrosion of the positive plates and it will attack the negative plates, forming nitrate of lead, which is converted into lead sulphate, releasing the acid to continue its destructive influence, and the consequent discharge of the negative plates. Ammonia will cause reduction of capacity and the formation of crystals by "creeping" about the edges of the cells. Iron is one of the most harmful of metals to be introduced into a lead-acid cell, for when in sufficient volume it will cause discharge of both the negative and positive plates, and its influence will continue so long as it remains in the electrolyte. Iron serves as a carrier of oxygen, and when in contact with lead peroxide it will form in the electrolyte a ferric sulphate. In this state it is attracted to the negative plates, where it will liberate oxygen and will discharge the negative plates and change to ferrous sulphate. As ferrous sulphate it is attracted to the positive plates, and there the process stated is repeated indefinitely. The action of manganese salts is identical with that of iron in carrying oxygen, the salts being changed in the electrolyte to permanganic acid or manganic sulphate. The permanganic acid carries oxygen from the positive plates to the negative, and after causing oxidization and forming manganic sulphate, it returns to the positive plate, where it releases the oxygen and is changed to acid form. This influence is repeated indefinitely.

(To Be Continued.)

The Warnes law that was to become effective Jan. 1, 1913, which imposed a registration tax of from $5 to $18 on different classes of automobiles and motor wagons owned by citizens of Ohio, has been declared unconstitutional as the result of a suit filed against the secretary of state by C. C. James, president of the Ohio State Automobile Association. The opinion of the court was that the measure was designed for revenue instead of merely affording protection for people and property. This decision will for the time being, at least, assumedly continue the law now existing. The opinion is of large importance to the owners of vehicles used for business purposes.

The annual convention of the American Road Builders' Association took place at Philadelphia, Penn., Dec. 9-13, and in connection with the meeting was an exhibition of road building machinery.

BOSTON MOTOR TRUCK SHOW.

Only Exhibition of the Kind in 1914 Has Large Business Possibilities.

The annual exhibition of the Boston Commercial Motor Vehicle Association will take place at Mechanics' building, Huntington avenue, March 17-21, continuing for five days, this allowing one business day between the conclusion of the pleasure car show on March 14 and the opening of the display of service machines. This will be the third successive annual truck show for Boston, and with the experience of the previous years the show committee believes that there will be an exhibition far superior to any yet held.

This will be the only exclusive motor truck show held during 1914, and while Boston exhibitions have always been national in character, this quality will be more pronounced than ever. The Boston dealers' organization is practically the only body in America that has continued display of service wagons, the Automobile Chamber of Commerce abandoning those held in New York and Chicago. Boston is recognized as the commercial centre of New England and the truck shows have invariably attracted people from all sections, with the result of numerous sales and the development of a great deal of prospective business.

The show will be under the management of Chester I. Campbell, who has directed every exhibition of motor vehicles held in Boston in the past 10 years, and he has neglected nothing that would in any way contribute to the attractiveness of the show to the business man. The show will not have the features that are characteristic of pleasure car exhibitions, but it will decidedly appeal to the man studying or investigating motor vehicles, for he will have opportunity to examine practically every machine sold in New England, make such comparisons as may be desired and obtain data that will be distinctly valuable.

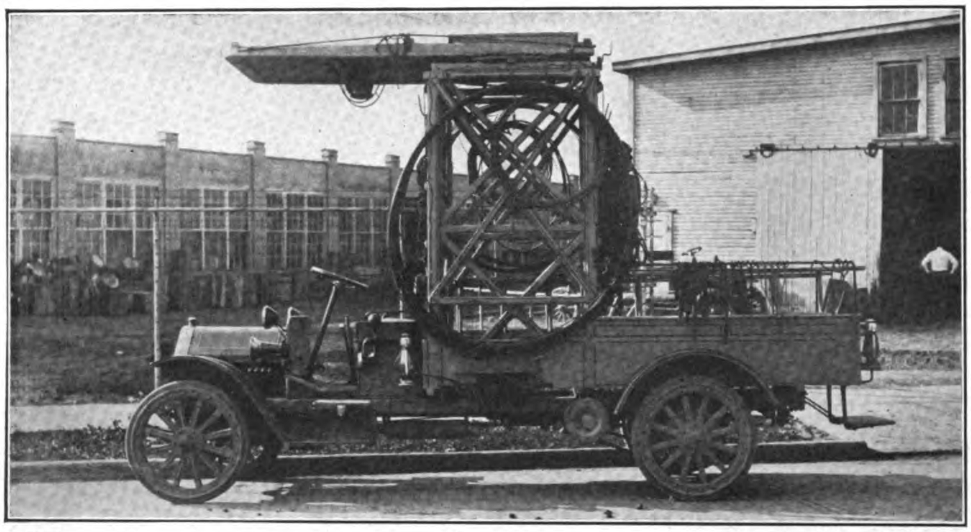
The show will continue five full days, and it will be at the end of winter, when the business men are planning for the activities that will be begun with the advent of warmer weather. Given over wholly to business vehicles and accessible from every part of New England in a few hours, it is expected that it will be especially productive. The possibilities for business at this show are regarded as extremely good, and this can be applied to practically any make of machine.

The M. Rumely Company, Laporte, Ind., has appointed as general manager of operations, Henry A. Waterman, who was general superintendent of the Milwaukee works of the International Harvester Company, and in charge of the designing and experimental work on tractors and internal combustion engines. Mr. Waterman, after being graduated from the Massachusetts Institute of Technology, was for two years with the Brown & Sharpe Manufacturing Company, Providence, R. I., as engineer.

FEDERAL TRUCKS FOR EMERGENCY WORK.

THE utility of the motor vehicle is accepted without question by business men and its economy is understood, but the fullest value of motorized equipment is not always realized by those who own it unless the conditions are studied and it is used to the best advantage. An admirable example of the possibilities is that of the Detroit United Railway Company, which operates the trolley surface lines in the city and vicinity, and which must provide means for maintenance of its service and restoration of lines whenever interruption happens. Time is extremely valuable when work of this character is needed and equipment that will economize it is not only desirable but is necessary.

For years horses were used by the department maintaining the street construction and lines, and believing that a better organization was possible, Ellsworth J. Burdick, superintendent of power, who has oversight of the power stations and the street construction, worked out a plan for using motor wagons. It was necessary to maintain a wagon to respond to fire alarms and to derailments of cars, and another to restore broken wires and make other repairs. He wanted machines that could be driven rapidly and which would have endurance, as well as sufficient capacity to carry tools and apparatus that would be needed in the event of any emergency that could be foreseen.



Federal Truck Equipped for "Overhead Trouble" Service and Used by the Detroit United Railway Company.

Detroit Street Railway Equipment.

He planned a central station where the apparatus he purposed to use could be located in readiness for a summons, and the service of two machines, selecting two Federal wagons. The station is at St. Antoine and Woodbridge streets, and here the equipment is always in readiness unless it is absent because of calls. The service is operated much the same as is a fire department, the calls being received by telephone and the wagon that is summoned being sent away almost instantly. Each wagon has a crew of four men, who are on duty day and night, seven days a week, sleeping in the house and being absent only for meals unless relieved. In this manner the fullest value of the men and machines is realized and work is done with celerity that is surprising. This is probably the only public service corporation that has adopted this plan, but the results have been extremely satisfactory.

One of the wagons is used for what is known as "ground work" and while it is a standard Federal chassis the body was built to designs submitted by Mr. Burdick, who planned his equipment requirements and the best means of carrying it. The body of this wagon is 11 feet length and is about five feet width, being built on a frame. This body is installed on the chassis so that the floor is about 30 inches above the ground. Five feet back of the driver's seat is a partition. Over the rear wheels are two tool boxes, each three feet length and nine inches width. Forward of the partition are carried bars, tackle, jacks, rope and tools used for moving and lifting derailed cars, this load weighing about 1100 pounds. The wagon is sent wherever a car is off the rails or is inoperative.

This wagon also is sent to all alarms of fire within a mile circle of the station, and to any fire that is in a street in which there is a track of the company. When the machine is sent out to fires it carries in addition to the equipment stated a steel tube and chain cradle that contains other tools and fitments that weigh about 2100 pounds. This cradle carries camelbacks and jumpers for use in crossing hose stretched across rails, and with its contents it is suspended from the ceiling by an air hoist. When the wagon is in the station it is under the cradle, so that in the event of an alarm the cradle is lowered into the space behind the body partition and without loss of time it can be dispatched. The machine is governed to 18 miles an hour instead of the regular 15 miles, and is fitted with cellular tires. Fast time is made by the crew, and frequently the machine is at fires ahead of apparatus.

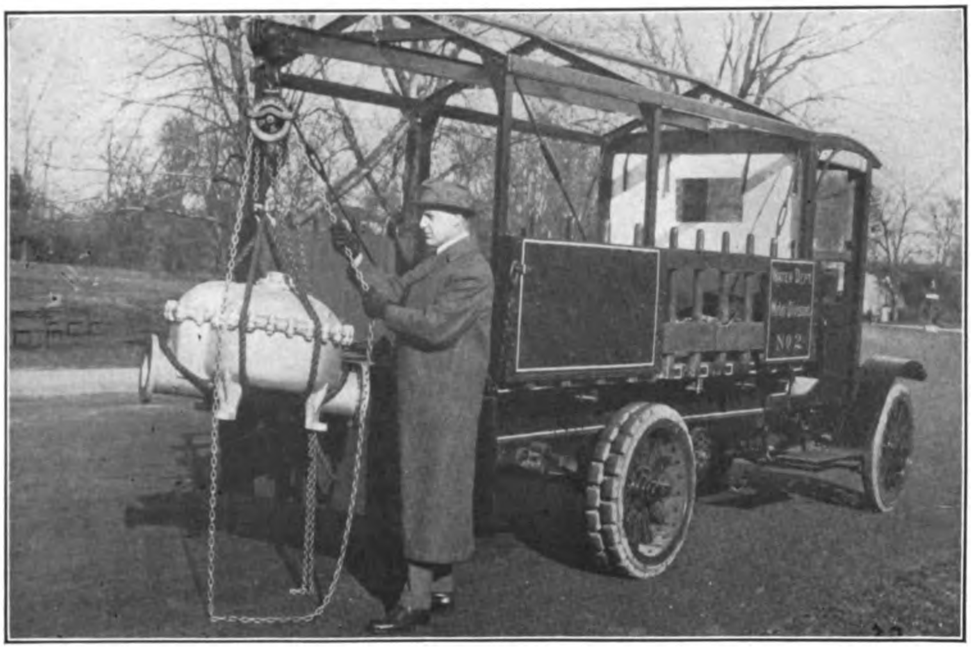
The second wagon is a standard Federal chassis equipped with a body designed by Mr. Burdick, and this is used exclusively for work on overhead construction, and it is sent to any point in the city where it is needed by the same system as the other. This machine has an open body and on this is mounted a standard Trenton tower for working on the wires. The tower is 10.5 feet height, but it may be extended to 17

feet. The equipment consists of rope, wire in coils, bars, wire guys, turnbuckles, wire cutters, blow torches, hand tools of all kinds, and whatever might be necessary for construction or repair work. Despite the tower the centre of gravity is low. The machine has the same speed as the other and it is rushed around the city in fast time.

Both machines have been in use about a year and have been in that period very thoroughly demonstrated. The system has worked out admirably and a service is afforded that would not be possible with any other form of equipment.

St. Louis Water Department.

Quite as interesting an installation has been developed by the St. Louis, Mo., water department for the use of its meter division. As it is necessary to handle a considerable number of large meters and these are both bulky and heavy, much time was required for loading and unloading, as well as the setting, and to economize the time a motor wagon equipment was devised. A Federal chassis was purchased and an open body installed. On this was built a frame with three 2.5-inch T bar steel stanchions at either side with a truss construction above them, with a four-inch I beam supported in the centre of the frame and extending 30 inches beyond the end of the body at the rear. On this I beam is mounted a half-ton chain hoist that can be moved from one end of the beam to the other. The frame is comparatively light, but it is given rigidity by gussets, ties and by diagonal rods and turnbuckles that are extended from the upper ends of the front and rear stanchions to the centre of the flooring, and is also given support by the sides of the body. The platform is 11 feet length and five feet width. The body, frame and equipment weigh 1500 pounds.



Federal Truck Fitted So Driver May Handle Half-Ton Meters Without Help, in the Service of the St. Louis, Mo., Water Department.

The largest meters used by the department weigh about 1000 pounds, and there are sizes that are graduated from that weight down. Because of the form the meters are difficult to handle without equipment, and with the idea of one man loading and unloading the heaviest of these, F. L. Beck, engineer of the meter and tap division of the St. Louis water works department, designed the body and the hoisting frame. When large meters are to be handled the truck is backed to the meter in the store house, a rope sling is passed around the machine and with the hoist it is raised to a height that will clear the truck platform and lowered. The truck can carry three of the largest meters and these can be moved from one place to another as easily as the smallest sizes. The truck may be backed to a sidewalk and the meters loaded or unloaded. The truck carries a meter puller that is used for loosening the flanged joints, this tool being designed to expedite the work and economize the time of the vehicle and its crew. The truck is driven from 15 to 30 miles a day, transferring men from one job to another, and according to the records of the department six men working in pairs with the truck can do as much work as 10 men working with five single-horse wagons. The saving possible through the use of the machine is considerable.

MILLER'S CATALOGUE.

Chas. E. Miller, with home office at 97-103 Reade street, and 14 branch stores located in the principal cities of nine states, has just issued his advance 1914 catalogue, which is designated as No. 27, and with an edition of 100,000. The catalogue is issued primarily for distribution at the automobile shows of the country and consists of 128 pages, describing and illustrating hundreds of specialties and standard equipment, accessories and supplies for motor vehicles, motor yachts and aeroplanes. Miller claims to be the largest and the oldest house in the country dealing in such goods. As manufacturer, jobber, importer and exporter he carries a stock that is unequalled and quick service is specialized. The catalogue is admirably designed and printed. A copy will be of distinct value to any person interested in motoring, motor yachting or aviation. It will be sent at request to any address.

John F. Soby is secretary and sales manager of the branch of the Brockway Motor Truck Sales Company of Homer, N. Y., which has been established at 250 West 54th street, New York City.

INTERNAL GEAR DRIVEN AXLES.

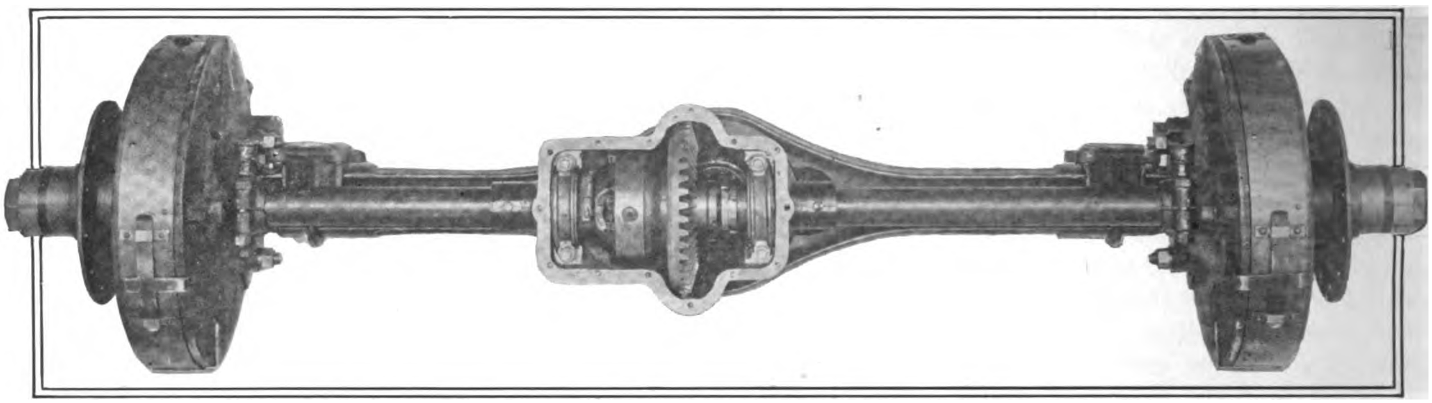
Torbensen Constructions Designed for Use with Gasoline and Electric Vehicles.

The Torbensen Gear & Axle Company, Newark, N. J., is now producing axles for service vehicles of the internal gear drive type, these being known as type R, for machines of 1500 pounds, and type S, for wagons of 3000 pounds capacity. The former size can be supplied with four different gear ratios, one of which is suited for electric vehicles, and the latter with three gear ratios. The principle of construction has been well established and the axles are maintained to be of high quality, affording extreme efficiency and having long endurance. The axles are identical save in that the parts of the type S are larger to meet the greater requirements of service.

The axle itself is an I section drop forged from selected steel, and the centre is made about double the width of the arms. At this section there is at either side a boss, through which is a circular eye or opening, and reinforcements for seating the bolts retaining the driving axle or jackshaft. At the ends of the axle are tongues which project above and below it to support the inner brake plate and the brake shafts. Outside of these tongues the axle is machined to cylindrical form. These ends are bored and reamed to a taper. The axle spindles are of chrome vanadium steel and are ground to the dimensions of the holes in the axle ends. The axles are then heated and when sufficiently expanded the spindles are forced into the holes, so that the metal, as it cools, holds the spindles so that they can only be removed by boring. The cylindrical portion of the axle extends into the wheel hub nearly to the centre line of the hub, so that the bending stress upon the axle is very small. The spindles are ample to resist all strains upon them. The spindles are fitted with either taper roller or ball bearings as may be desired by the manufacturers who are to use the axles.

On the back side of the axle is the jackshaft, which is housed in a central section divided vertically and bolted together, with shaft tubes extending from this section to fittings bolted to the axle carrying the outer bearings. On the forward side of the axle is bolted the housing that carries the bearings for the pinion shaft. The differential is mounted in the axle housing on either ball or roller bearings and the axle shafts carry pinions at the outer ends. The drive is by these pinions meshing with an internal ring gear that is a drop forging, and is pressed into the hub of the wheel, being secured by 12 rivets. These rivets serve as keys and lock the ring into the hub. Two overlapping shoulders protect the gear and pinion against dust and an annular ring laid in a groove in the inner running joint serves like a piston ring and retains the lubricant.

These axles are fitted with a service brake of the external type with bands contracting on pressed steel drums surrounding the internal gear, and internal cam expanding brake shoes operating within these drums for emergency. The type R axles are made with reductions of 5.25:1, 6:1, 6.8:1 and 11.3:1, the last named being generally used for electrics. The type S axles are supplied with reductions of 6.15:1, 7.20:1 and 8:1. These axles have been carefully designed and the principles have been established by use for years. The claim is made that the internal gear drive insures a very uniform application of power, and there is but little variation in power losses. The axle is constructed of high grade material and aside from renewal of lubrication from time to time it requires minimum attention.



The Torbensen Internal Gear Driven Rear Axle, Suited for Gasoline and Electric Vehicles, Made in Two Types and with Different Reduction Ratios, for 1500 and 3000-Pound Machines.

The Capitol Hill Truck Manufacturing Company has been formed at Denver, Col., to build electric service wagons. The president is Charles A. Scott, who has other interests in the automobile industry. The plans of the company are to build a factory in Speer boulevard that will have a capacity of perhaps 100 vehicles annually, and the purpose is to turn out at least 50 the coming year. The design that is now being considered is for a shaft drive machine with the battery in three sections, one in front under a hood and the other two carried on running boards at the side. The vehicle is not an uncertainty, several which embody the chief qualities sought having been built and used for considerable time in experimental service in the city of Denver.

AUSTRIA'S ELECTRIC POSTAL WAGONS.

An Installation in Vienna Which Comprises 30 Electro-Daimler 2.5-Ton Vehicles—Garage Facilities, Battery Care and Construction of the Machines.

ONE of the most interesting installations of electric vehicles abroad is that recently inaugurated by the Austrian Postoffice Department in Vienna. This is particularly true, because, for reasons which do not appear exactly clear in this country, foreign business men have not looked with favor upon the use of electrics. The official indorsement of the Austrian imperial government is expected to mean much to this branch of the industry in Continental Europe, and very probably in Great Britain, as well.

General View of the Garage Where Electro-Daimler Postal Wagons Are Housed in Vienna, Austria.

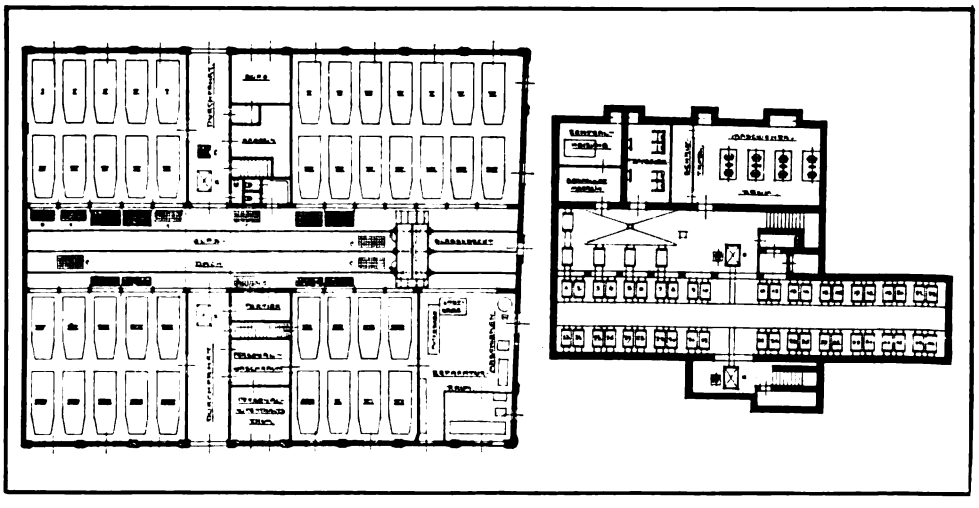
The installation comprises 30 Electro-Daimler wagons of practically 2.5 tons capacity, built by the Austrian Daimler Motoren-A. G., of Vienna, a concern which is much better known in America, at least, for its production of Austro-Daimler gasoline cars and trucks. The service was begun June 15 of this year, but not until experimentation covering a period of more than a year had demonstrated to the satisfaction of General Postmaster von Uhl that the electric was suitable in every respect.

It is not understood, as the result of correspondence with the maker of these cars, that they are owned by the government, inasmuch as the service is supplied by a private concern, the Austrian Daimler-Tudor Omnibus-Gesellschaft. This company has been operating electric omnibuses in Vienna for some two years, and it was from observation of these vehicles that the government officials first had their attention drawn to this type of transport.

Having decided to experiment with electrics, the imperial wagon works, Jacob Lohner & Co., Vienna, was commissioned to construct a special body design to meet the needs of the postoffice department, in the transportation of packages and mails, and this was fitted to an Electro-Daimler chassis. This machine was delivered to the government March 1, 1912, and was at once placed under the charge of the omnibus company. During the year this was driven 17,000 kilometers (about 10,000 miles), and careful observation was made relative to its economy and efficiency. At the conclusion of this experimental period, the omnibus company made public the following statement:

> General Postmaster von Uhl considered both types of vehicle and found that the electric possessed the advantages of safety, cleanliness, simplicity, noiselessness and of being odorless. It was also found that the cost for power was 20 per cent. less. The decision was made easily.
>
> In Europe, it has been felt that, on account of the disadvantages of the battery, electric power was not practicable for trucks, omnibuses, etc., while in America the use of specially heavy electric trucks has increased rapidly. With the constant advance in the price of gasoline, the electric will be used more and more, especially by such enterprises as this, where the installation is large. This year, this type of vehicle is gaining ground all over Europe, as is true in America. It is a mistaken idea that the battery gives trouble, as is borne out by a service of 15 months on a given line in Austria, covering 500,000 kilometers without interruption.

The postoffice machines in question are housed in a special garage, work on which was begun Oct. 29,



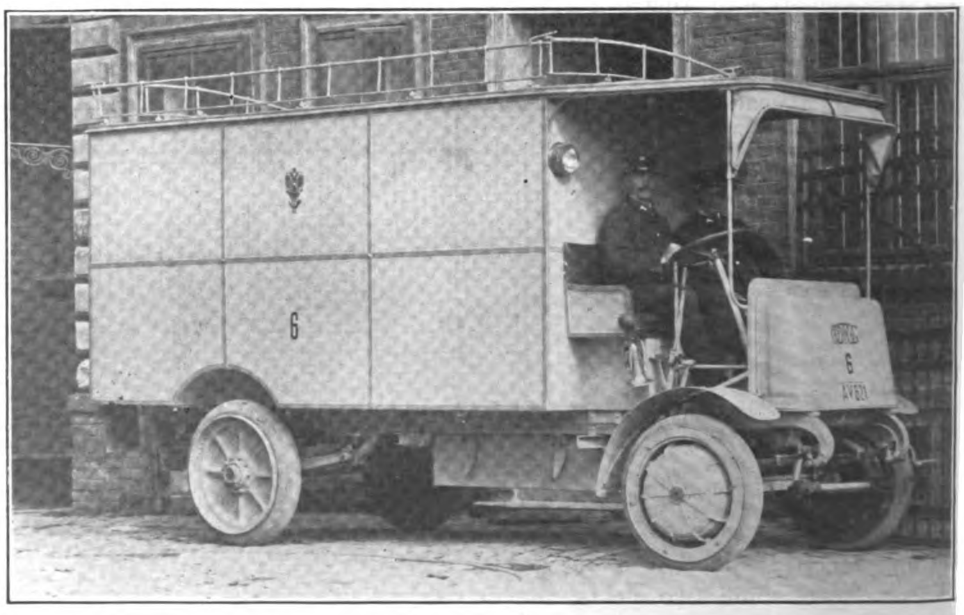
Plan View of Postoffice Department's Garage in Vienna, Showing Arangement of Stalls on the Main Floor at Left, and Location of Battery Room, Etc., in Basement at Right.

Front View of Electro-Daimler Postal Wagon, Indicating Construction of Forward Axle, Etc.

1912, and finished in May of this year. The building is located with a frontage on three streets and is 40 by 31 meters (131 by 102 feet). It consists of one story and basement, the cars being stored on the main floor, and the battery room being in the basement. The building was erected to accommodate 45 machines, although but 30 have been installed as yet.

An accompanying diagram indicates the interior arrangement. It will be seen that the machines are assigned to stalls on either side of a main driveway through the building, and the government demands 10 square meters for each. Cars are not turned around in the garage under their own power, but are driven upon a turntable, and this turntable is mounted on rails in such a manner as to permit its being used on any portion of the main driveway.

Whenever it becomes necessary to change a battery, the car is shunted into an aisle branching off at right angles to the main driveway, at either side, and is located over an opening into the basement. An elevator, bearing a platform, is hoisted through this opening until the top of the platform bears against the bottom of the chassis. The battery is carried on the chassis in such manner, being supported by bars, as will be explained in more detail later, that a simple movement of these bars frees the crate and lowers it to the platform. The elevator then disappears into the basement and a fully charged battery is hoisted into place. The whole operation consumes between one and two minutes.



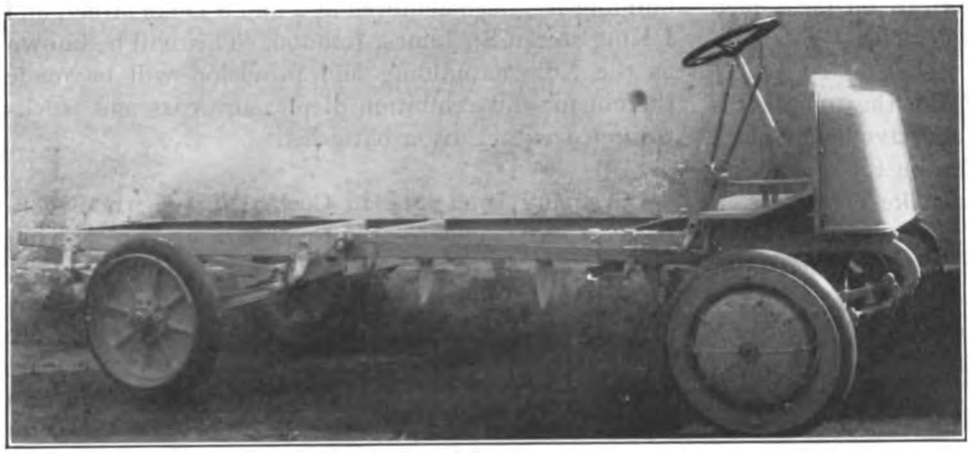
One of the Electro-Daimler Postal Wagons Which Are Utilized by the General Postmaster at Vienna, Austria.

There were two good reasons for this arrangement of floor space, the first being that of segregating the battery work and providing for a quick exchange of batteries, and the other, the necessity for economizing on space so as to provide for a power room, stock room, office and a large tool room and repair shop.

The power room is located in the basement. Current is delivered to the garage from the city electric works and at a voltage of 5000. This is transformed to 220 volts, alternating current. This is again transformed to 110 volts, direct current, for charging purposes, in a special room equipped with the very latest electrical appliances for this work.

The chassis, which are the product of the Austrian Daimler Motoren-A. G., are distinctive, in that the motors are located in the front wheels, a type of construction which is not entirely new in American practise, however. The frame is of pressed alloy steel, and this is mounted on extra long springs designed to possess easy riding qualities. The axles are of chrome steel, and the rear wheels of pressed steel, mounted on ball bearings. There are two sets of brakes, in addition to the electric brake which operates on the front wheels, and both of these act direct on rear wheel drums. Tires are solid rubber, 850 by 140 mm front and 900 by 160 mm rear. The wheelbase is 3300 mm (130 inches).

The motors in the front wheels are with the pole pieces arranged in the form of a star, while the armature is attached to the case forming one side of the wheel, supported on either side by ball bearings, and the assembly is so bolted together as provide practically a unit construction. The armature is wound in the conventional manner, and the collector brushes are so positioned that the vertical vibrations of the car cannot injure them. The brush bridge is of the ring design, located on the forward part of the axle.



Stripped Chassis of the Electro-Daimler Postal Wagon, Indicating the General Constructional Features.

ing through a neat application of the worm and worm wheel principle. Steering is accomplished by a hand wheel of the conventional type.

The bodies are of special design, conforming to the specifications supplied by the postoffice officials, and are the product of the imperial wagon works, Jacob Lohner & Co. They are entirely enclosed, with entrance from the rear, and may be locked so that the driver and attendant may not reach the contents. Inside is a special compartment for valuable packages, this box being lined with zinc. Provision is made on top for carrying extra large packages, a wire fence preventing dislodgement. This fence is made so that it may be turned down, on account of the entrances to several of the postal stations, the machines being driven directly into the buildings and the contents being handled by government officials alone.

As the service is furnished by a private corporation, each vehicle is fitted with a speedometer, payment being made for each kilometer travelled. The wagons have a guaranteed radius of 35 kilometers (21.7 miles). The tires also are supplied on a guaranteed service basis.

The construction is such that by removing the outer safety casing or cover, the collector with its brushes is fully exposed and accessible. The motors are dust and water tight, and easily dismounted. They are of the high speed type, 90-volt, with maximum of 15 horsepower.

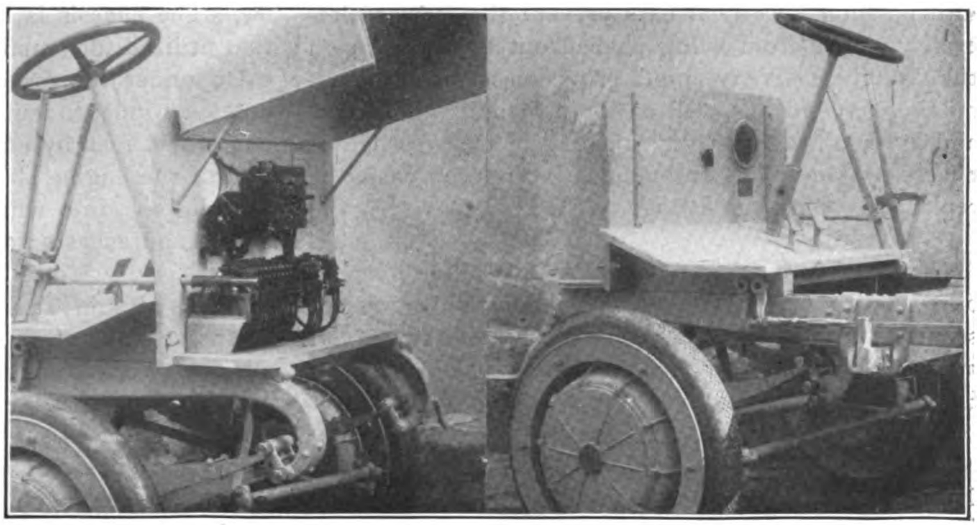
The battery is carried in a tray in the centre of the chassis at the front, as indicated in an accompanying illustration. The method of fastening is extremely simple, two bars, or parallel rails, one at the front and the other at the rear, as shown, being inserted in clamps provided for that purpose. With the platform on the elevator pressing against the bottom of the tray, as explained above, the weight is taken from these bars and it is an easy matter to withdraw them, when the battery tray is immediately released from the chassis.

The batteries are each 42 cells, type VI Ky 285/4, and are rated at 300 ampere-hours, with five hours discharge rate, and with maximum capacity of 60 amperes. Their weight is 870 kilogrammes (1918 pounds). In order that there shall be no opportunity for delay in the service the company maintains 56 of these, so that it practically is possible to have one battery in reserve for each truck at all times.

All electrical apparatus—controller, switch, meters and coil—is carried at the front of the dash, where it is protected from dirt and dust by a short hood. This is readily accessible by lifting the cover, which is hinged at the top and provided with rods to hold it in an upright position. The controller gives three speeds forward and one in reverse, and operates the electric brake on the front wheels. The driver is at the right, with two levers also at the right. One of these actuates the emergency brake on the rear wheels and the other the controller, the latter work-

GENERAL NEWS FROM ABROAD.

Another Electric Truck Maker—As a result of the favorable impression made upon B. M. Drake of Drake & Gorham, Ltd., London, England, during his recent visit to the United States, this concern, which is well known in Great Britain as a firm of electrical engineers, is working on plans for an electric truck, which will be placed on the British market in the near future. Mr. Drake says he was particularly interested



Details of Electric-Daimler Construction: At Left, Location of Controller and Electrical Apparatus, Showing Worm Drive Employed; at Right, Front Wheel Casing Enclosing Electric Motor, Etc.

in the figures obtained from American business men regarding the economy of electric vehicles.

Motor Trucks in Ireland—While the merchants and business men in Dublin, Ireland, have been studying the subject of motor transportation for some little time, it is stated that the recent strike of carters in that city has had the usual effect abroad. Many concerns, who were compelled to adopt some means of securing immediate delivery, decided at once in favor of motor trucks, and the success of the plan has been so marked that orders for from five to eight vehicles have been received by makers in several instances.

Trucks at Paris Salon—Because of the many conflicting plans attendant upon the proposed showing of commercial motor vehicles in connection with the annual Paris Salon, only 21 different makes were placed on display. At the last moment the government decided to permit the erection of a temporary structure in the Cours la Reine, adjoining the Grand Palais, and it was in this that the vehicles were shown. The exhibition was particularly interesting from the fact that steam machines were featured much more extensively than heretofore. This type of vehicle has not received decided encouragement in France, although it has been utilized with a large measure of success in England, and Germany and some other Continental countries. Another feature of the exhibit was the number of dumping wagons on display. As might be expected, a majority of the chassis shown were of the subsidized types.

Saurer Ambulance for Russian Army—Adolph Saurer of Switzerland has just made delivery of a Saurer ambulance to the Russian military officials, which discloses some interesting innovations in the body arrangement. The interior provides space for six stretchers, three on a side, suspended by coil springs, also for two seats, which are intended either for attendants or for wounded able to sit. A system of pulleys serves to hoist the two topmost stretchers into position. Vertical bars prevent the forward lateral windows from being pushed out by the men on the stretchers. Very ample provision is made for admitting daylight, as well as for protecting the driver and attendant against inclemencies of the weather. If necessary, the whole ambulance fixtures can easily be replaced by omnibus fittings.

Wants South African Agency—A. Collins, Maritzburg, South Africa, announces that he is desirous of securing an agency for a reputed make of commercial motor vehicle and for any good brand of solid tires. He invites correspondence direct.

Edison Batteries in England—The increase in the demand for Edison batteries in Great Britain has been such that it has been found necessary to secure additional room for Edison Accumulators, Ltd., and a new building has been acquired at 2 and 3 Duke street, and 1 King street, St. James, London. This will be known as the Edison building and provision will be made therein for the exhibition of pleasure cars and trucks equipped with Edison batteries.

Germany Interested in Costa Rica—German consular reports indicate that there is a certain demand for interurban motor 'bus lines in Costa Rica, and German manufacturers are urged to cultivate this market. It is explained that the cross country roads are not suitable for automobile use, but within the past year some 18 motor cabs have been installed in San Jose with satisfactory results.

Japanese Government Interested—It is reported from Tokio, Japan, that the war office has decided to purchase a number of military motor vehicles. Not only will a motor wagon corps be formed for transporting provisions, etc., and the officers, but also a flying corps and a wireless telegraphy fleet of automobiles, provision for which will be made in the budget for next year.

Demand in Straits Settlements—The registrar of imports and exports at Singapore reports that the estimates of expenditures for 1914, for the Straits Settlements, include provision for a motor truck and four dumping wagons at a total cost of $40,000. The demand for all types of motor vehicles in this section is growing rapidly.

Experiment with Electric Ambulance—The Metropolitan Asylums Board, London, England, has decided to experiment with electric driven ambulances. Two chassis have been purchased from the Cedes Electric Traction Company, Ltd., the purchase price being about $1950, exclusive of the body and batteries.

Schneider Water Filter Plant—The French military authorities have been investigating the possibilities of an automobile water filter plant for army service. The chassis is a standard Schneider, similar to that utilized for omnibuses in Paris. The motor is located under the driver's feet, and for filtration purposes, an independent pump carried on a two-wheeled bogey is driven by an electric dynamo on a continuation of the engine shaft. Two tanks are united by a flexible pipe, into which the water is filtered through cotton and asbestos discs.

Paris Would Tax Trucks—The prefect of the department of the Seine, Paris, France, has asked permission to impose a tax on commercial motor vehicles, based upon the weight of the car and the horsepower rating. The fees suggested include $60 a year for 25 horsepower vehicles weighing 3.5 tons, and $200 for a 50 horsepower machine weighing eight tons, if shod with rubber tires, or $300 with steel tires. Other proposed rates are in proportion to those selected.

Municipal Service Equipment

FEDERAL FIRE WAGON.

A New Body Design Which Has Met with Decided Favor During the Past Season.

The Federal Motor Truck Company, Detroit, is directing special attention at this time to its combination chemical engine and hose wagon, a body design that is fitted to the regulation Federal truck chassis. The first vehicles of this type were produced by this company about a year ago, and the popularity which has resulted from the original installations has been such as to win a large measure of success for the company in this field and the demand is increasing very rapidly in many sections.

The capacity of the chassis is one ton, and the wheelbase is 144 inches. The engine is rated at 30 horsepower and the maximum speed of the wagon is placed at 22 miles an hour. Control is at the left side.

Federal One-Ton Chassis Equipped as a Combination Chemical Engine and Hose Wagon.

Brass clutch rails extend the full length of the body to the rear stepboard, on which are two spindles for hose nozzles. The equipment includes: One thousand feet of standard fire hose, 35-gallon chemical tank with connection for hose from the hydrant, two five-gallon hand extinguishers in brass receptacles, hose basket suspended over the front of the body with capacity of 250 feet of chemical hose, two 20 to 25-foot extension ladders, poles, hooks and many other implements necessary for fire fighting.

WANTS MOTOR APPARATUS.

Jersey City Commissioner of Public Safety Says Present Equipment Is Antiquated.

Frank Hague, commissioner of public safety in Jersey City, N. J., has asked the city commission to permit him to expend $168,525 for new equipment and to appoint extra men. Concerning the acquisition of motor apparatus, he has the following to say:

Many of the engines now in service are antiquated. These must be replaced sooner or later by modern apparatus. A motor driven aerial truck to replace hook and ladder No. 6, that has outlived its usefulness, would work wonders. Such an apparatus is absolutely necessary and should be acquired at once. It could be pressed into service on second and third alarms in any section of the city.

There is not a single spare or reserve engine in the department. This is a serious condition, as, if an engine is disabled when in service, there is none to take its place. In all well regulated fire departments a contingency of this kind is provided for. This should be the case in this city, and I am firmly convinced that if two motor driven engines were put in service every emergency would be met. Results accomplished would more than pay for the money expended.

NO HORSES DOWN TOWN.

Tacoma, Wash., Witnessed an Important Event in Its History Last Month.

For the first time in the history of Tacoma, Wash., the fire department responded to an alarm of fire in the down town district last month without a horse drawn vehicle. Every piece of apparatus that answered the call from the Realty building on this instance was gasoline propelled. In commenting upon the incident Chief George McAlevy voiced his regret concerning the passing of the horse, although he appreciates the value of the newer equipment.

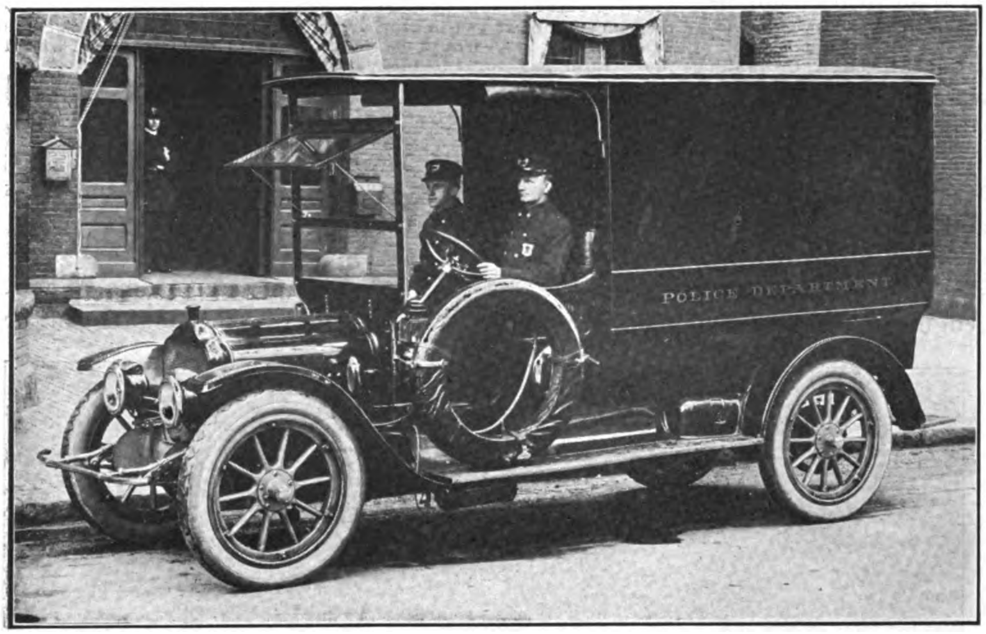
"While the good old horse has not been entirely eliminated from the fire department in this city", said he, "he will never again answer the calls in the down town district". Some of the stations in the outside sections still have horse drawn wagons, but it will only be a question of time when these will be replaced with automobile equipment. "It may be that old Dobbin will receive a call once in a while, in cases of emergency, but I doubt it", concluded Chief McAlevy

WHITE PATROLS IN SERVICE.

Stability and Efficiency of Worcester Equipment Is Satisfactorily Demonstrated.

In October, 1911, the police department in Worcester, Mass., placed in service one combination patrol wagon and ambulance and a vehicle equipped exclusively for ambulance work. About a month later another combination machine was added. All three chassis were of White make, produced by the White Company, Cleveland, O. The stability and efficiency of these three machines has been so well demonstrated during the past two years that a fourth has now been purchased and will be installed shortly.

During the two years which the three machines have been in service they have answered an aggregate of 18,728 calls, and have covered 43,455 miles. As ambulances the wagons are expected to go anywhere, and several instances are on record in which they have been called upon to traverse places that an ordinary motor car driver would consider impossible. Trips have been made through fields and wood lots, and often the way has been strewn with rocks or the mud has been hub deep.



White Combination Patrol Wagon and Ambulance, Which Has Seen Two Years' Service with Department in Worcester, Mass.

All three machines have been in constant service, with the exception of two or three days, when overhaul work has been deemed advisable. Each is in good running condition, Chief Mathews being of the opinion that they are practically as serviceable in every way as when they left the factory. The expense for repairs has been so small as to be almost negligible.

Aside from the economy afforded, as compared with horse equipment, the people of Worcester have had many examples of the value of the ambulance feature, in the numerous quick runs which have resulted in the saving of human life. This has been particularly true in cases of asphyxiation and drowning, where the pulmotor has been rushed to the scene. There also are hundreds of instances in which people have been wounded and have been saved from serious results through the ability of the police department to make rapid time in reaching the hospital or medical attention. Surgeons in charge of these patients state that many of them would have died had they been compelled to wait for a horse drawn ambulance.

ECONOMY OF MOTOR PUMP.

Experience of Pasadena Department Shows Decided Saving Over Steam Engine.

The use of motor pumping engines in the fire department has been a subject of much inquiry and investigation by fire chiefs throughout the country. It is not often that it is possible to give dependable figures as to the maintenance cost of this type of apparatus, covering a period sufficient to permit of satisfactory comparison with horse drawn steam pumping engines.

The department in Pasadena, Cal., has an automobile of this type at the station on Mentor avenue, and a steamer drawn by three horses at the house on Dayton street. The former has been in service one year, and the two have been so situated as to answer about the same number of alarms and to cover approximately the same mileage.

In his annual report Chief Arthur M. Clifford states that the maintenance cost for the gasoline pumping engine for the year was $51.40, in answering 43 alarms and travelling 61 miles. The expense for the steamer drawn by three horses was $685.32, and it answered 45 alarms, covering 63 miles. The difference is $633.92.

In commenting upon this showing Chief Clifford calls attention to the fact that the saving would not be as marked between the Mentor avenue apparatus and other horse drawn equipment in the city, for the reason that with most wagons only two horses are employed.

INVESTIGATION IN PITTSBURG.

Report Recommends Motorization of Fire Department After Tests Have Been Made.

At the request of the city council in Pittsburg, Penn., two bureaus of municipal research and efficiency engineers have investigated the fire department in that city with the purpose of recommending

such changes in management and equipment as would seem desirable. One of the investigators lays great stress upon the matter of motorization, and makes the following recommendations:

That accurate tests and records as to motor equipment be carried out and maintained.
That these tests and records establish the type of motive power to be purchased.
That the council withhold the $120,000 for new motorized apparatus until this is definitely established.
That motorization be undertaken first in the outlying districts.
That automatic decrease in the size of the bureau be allowed to eliminate the 139 men not required.
That motorization be pursued with a speed that will permit the reduction to be made according to the natural elimination of the members of the bureau.

NEWS FROM VARIOUS CITIES.

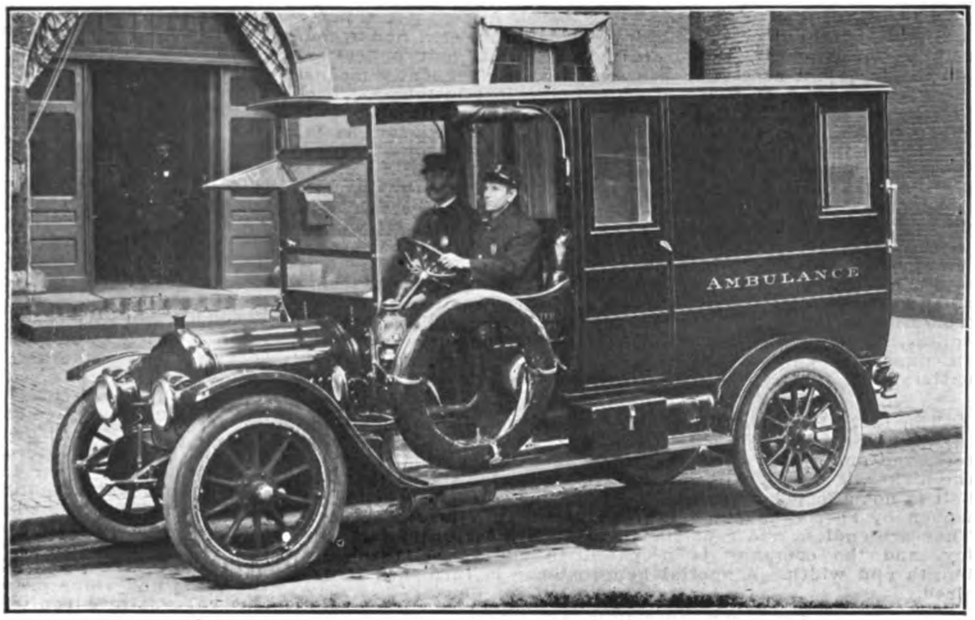
In the Market—The following cities are considering the purchase of motor driven fire apparatus: Suffolk, Va.; Livingston, Mont.; New Haven, Conn., pumping engine; Kearny, N. J., fire engine; St. Augustine, Fla.; Rochester, N. Y., two combination chemical and hose wagons; Providence, R. I., two combination hose and chemical wagons; Douglas, Ariz.; Oklahoma City, Okla., pumping engine; Manitowoc, Wis.; Chico, Cal., hose car; Hot Springs, Ark., chemical and hose car; Ottawa, Ill.; Vallejo, Cal., combination chemical and hose car; Chicaga, Ill., two combination chemical and hose cars; Corsicana, Tex., combination chemical and hose car; Oxnard, Cal.; Lestershire, N. Y.; Reading, Penn.; Carthage, Mo., one piece; Merchantville, N. J.

Motors in Grand Rapids—When motor fire equipment is being considered by other cities, Grand Rapids, Mich., has a high position among cities of its size. There are now 10 pieces of this apparatus in use by the department, including five hose wagons, two chemical trucks, two tractors, four ladder trucks and a tractor for a steamer. In addition there are now being constructed a tractor for a ladder truck and an aerial ladder to be drawn by a tractor. Besides the apparatus there are a number of automobiles for the use of the officials of the department.

Cleveland's Apparatus in Snow—The recent heavy snowstorm at Cleveland, O., brought out forcibly the superiority of the motor driven fire apparatus over the horse drawn vehicles. On account of the bad traffic conditions during the storm orders were given that none of the heavy horse drawn hook and ladder trucks, steamers and hose wagons should leave their respective houses. At one of the houses a Peerless tractor had been installed to haul a 65-foot ladder truck, and when a fire alarm came in at the height of the storm this tractor, drawing the six-ton ladder truck and a crew of 13 men, weighing more than another ton, made the trip successfully.

Hartford's Police Patrols—After being entirely overhauled and rebuilt the police patrol automobile of Hartford, Conn., has been returned to the service. The police department of that city is now equipped with two patrol automobiles and an automobile ambulance, all three of which have demonstrated the highest type of efficiency.

KisselKar Wagon for Fall River—A KisselKar hose and chemical wagon has just been delivered to the fire department of Fall River, Mass., which has won the unanimous approval of Chief Davol and the board of fire commissioners after its official test. The apparatus is mounted on a six-cylinder chassis of 60 horsepower and is the third piece of motor equipment purchased by this city.



White Ambulance in Service with Worcester Police Department at Headquarters.

Installations of Apparatus—Motor driven fire apparatus has recently been installed in the service of the following cities: Reading, Mass., triple combination truck; Amesbury, Mass., combination hose and twin tank chemical; Springfield, Mass., electrically operated Seagrave ladder truck; Thompsonville, Conn., hook and ladder truck; Holyoke, Mass., two tractors and two combination hose and chemical wagons; Roselle, N. J., combination pumping engine; Sandusky, O., triple combination pump, chemical and hose car; Pasadena, Cal., two combination chemical and hose cars and a 75-foot aerial truck; Red Bank, N. J., two piston pumping engines; Des Moines, Ia., Dayton airless tires for the motor apparatus.

New Commercial Car Accessories

Volcano Electric Primer.

The Volcano electric primer differs from the usual priming devices in that the vaporization of the fuel is obtained by the heat of electricity. A plate device is fitted inside of the intake manifold of the motor and gasoline is led to it by tubing. The capacity of the intake member is proportioned to make an inflammable mixture. A small dash vessel contains the priming fluid and a control member is also provided. Current is supplied by a six-volt storage battery or dry cells. The maker states that the dash container has sufficient capacity to provide about 150 starts when the motor is cold.

Motophone Horn.

The Automobile Supply Manufacturing Company, 220 Taaffe Place, Brooklyn, N. Y., is introducing a new horn known as the Motophone. It is mechanically operated, a slight pressure on a conveniently located lever resulting in a loud, steady, pleasant sound. The operating mechanism has been perfected by the maker after long experimentation and it is stated that the tests to which it was subjected were unusually severe. The maker calls attention to the convenience of the signal, in that its operation does not depend upon batteries. Throughout the workmanship and material are high class.

J & B Magnetic Lift.

In the overhaul of the motor, transmission, etc., and when making adjustments, the dropping of a nut, bolt or cotter pin in places not accessible with the fingers, frequently means the disassembling of parts to recover the lost members. The J & B Manufacturing Company, Pittsfield, Mass., has brought out a useful, as well as practical, tool for recovering parts dropped in the pan or mechanism of the car. It comprises an electromagnet in sections, having a handle containing a switch for opening and closing the circuit between the device and the battery. These sections are so constructed as to carry the current from the handle to the magnet end without wires, and as the electromagnet is always at the end of the tool, maximum lifting power is provided at the service end. The device is designed for the owner, repairman and service station, and the maker states that it has sufficient power to lift valves from the cylinder heads. The tool weighs complete but 12 ounces, has a lifting power of 12 pounds, consumes but half an ampere of current and may be utilized with any six-volt battery.

Curry Fan Belt.

The C. & B. Hinson Company, Cincinnati, O., is manufacturing a fan belt designed particularly for model T Ford motors, and one of the qualities of the material, as indicated by the maker, is that it will not stretch. It is also stated that the belt is not affected by grease, oils, dirt or heat. The belts are woven by special machinery and treated by a secret process. They are endless and constructed to fit any design of fan pulley, and the company is prepared to supply belts in any length and width. A special belt fastener is furnished if desired.

Ten Eyck Automatic Air Pump.

The Ten Eyck automatic air pump is manufactured by the Ten Eyck Pump Company, Auburn, N. Y., and may be employed for inflating tires or in connection with a compressed air type of motor starter. The gearshift is automatically controlled by a separate piston and cylinder, which is operated by the pressure in the tank or tire. The back pressure from the air receiver slides the pump gear into mesh with the driving gear, the pump gear running idle until the two gears are partly meshed. The clutch is then engaged. Disconnecting the pump from the air receiver allows the pressure to escape from the automatic cylinder and the gears are disengaged by means of a spring. In this operation the clutch is first disengaged, permitting the pump gear to run idle while being drawn out of mesh. This arrangement makes easy engagement and disengagement of the gears without reducing the motor speed. All parts are constructed of high grade material and the workmanship is first class. The pump is 10 by 4.5 inches, weighs 10 pounds and has a capacity of two cubic feet a minute.

V Hot Air Valve.

The use of heated air in carburetion is becoming more general and the usual method is to convey the warm air from proximity of the exhaust manifold to the air intake of the carburetor by means of a flexible tube. A different application of the principle is noted in the V hot air valve marketed by V Air Valve & Manufacturing Company, 1648 Tremont street, Denver, Col. It comprises a hood like member, which is clamped on to the exhaust pipe or manifold; flexible metallic tubing for conveying the heated air, and the V valve. The last named member is screwed into the intake manifold above the carburetor and control of the valve is by a wire cable operated by a lever clamped to the steering column under the wheel. This permits the driver to regulate the amount of air admitted according to atmospheric conditions, etc., also to utilize the control for flushing out the cylinders with fresh air, as in coasting down hill, for example. The maker states that considerable more mileage is obtained to a gallon and that further economy results, in that at high piston speeds the emergence of the fuel from the jet is restricted without affecting the output of the motor.

Auto-Queen Wrench Set.

The Auto-Queen wrench set is produced by the C. M. B. Wrench Company, Garwood, N. J. The No. 11 set includes a ratchet wrench, universal joint, long extension, spark plug socket and 15 sockets. The last named members provide for a number of different sized nuts and bolts, both square and hexagonal. The outfit comes in a neat, substantial hard wood box and weighs seven pounds.

Breeze Tank Valve.

The Breeze Carburetor Company, Newark, N. J., is marketing the Breeze 4-in-1 tank valve, which obtains the reserve capacity of fuel without the auxiliary tank being in the fuel container. Two outlet levels are utilized in the tank, the service member being slightly higher than the reserve, and according to requirements. Two controls are provided, one for each outlet, also two "off" positions, connection between the indicating plate and valve proper being made by a rod arrangement. The valve is provided with a gauze strainer, also a screw plug member for cleaning and draining. One of the features of the valve is that it may be locked, preventing use of the car by others than those intended.

THE A B C OF MOTOR TRUCK IGNITION.

Part XVI—Characteristics of Mea True High-Tension Magneto, Employing Bell Shaped Magnets Placed Horizontally and in the Same Axis with the Armature—Independent and Dual Equipments.

By C. P. Shattuck.

PREVIOUS discussions of magnetos dealt with those conventional forms utilizing a breaker box or interrupter mechanism which permitted the driver to control the break or interruption of the primary current, or, in other words, to advance or retard the spark. This has been designated as variable advance, a construction making for motor efficiency if handled intelligently by the operator. It has been pointed out that the greatest efficiency is obtained from the magneto when the greatest number of lines of force are cut and that the quality of the spark, its heat value, is dependent largely upon the position of the armature with reference to the magnetic field, or the relation of the armature and field, when the spark is created.

With the high-tension magneto the correct relation of position is established twice each revolution of the armature, or at intervals of 180 degrees, and two sparks may be obtained each time the armature is revolved once. The timing of the spark, as previously explained, is by causing the breaker or contact points to separate earlier or later, and if the magnetic field cannot be moved the relation between the armature and the field must be changed if the spark be advanced or retarded.

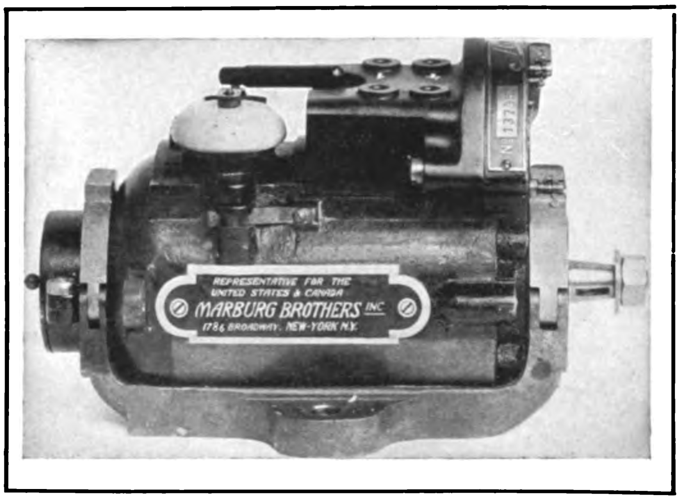

Fig. 85—Mea True High-Tension Magneto, Productive of Uniform Spark in All Positions of Timing as Breaker Is Attached to the Magnet, and Is Advanced and Retarded Simultaneously with It.

How Mea Differs.

The Mea magneto, marketed by Marburg Bros., Inc., 1790 Broadway, New York City, several types of which are illustrated herewith, is distinct from the designs discussed, in several particulars. The most noticeable feature of the construction is the use of bell shaped magnets instead of the permanent horseshoe type, and these are placed horizontally and in the same axis with the armature, instead of at right angle to it as with conventional designs.

The maker points out that this makes possible and practicable the simultaneous advance and retard of the magnets and breaker, instead of the latter alone, insuring maximum efficiency or heat value from the spark irrespective of the timing. This is due to established retarded positions between the magnet and the armature field.

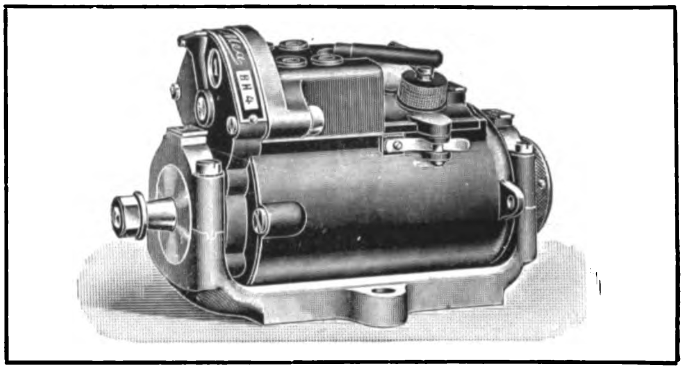

Fig. 86—The Mea Magneto, Type BH4.

Fig. 89 shows how Mea magnetic fields advance and retard. The range of timing of the Mea magneto is from 45 to 70 degrees, depending upon the size and type of instrument. The timing range, however, can be increased to any number of degrees desired. In other words, the relations are not changed and there should be the same value of spark at all times.

Value of Hot Spark.

The value of the equally hot spark in all positions of timing is well understood. The magneto can be put at full retard and the engine started easily if there is an explosive mixture in the cylinders. The maker further states that the magneto may be set as far ad-

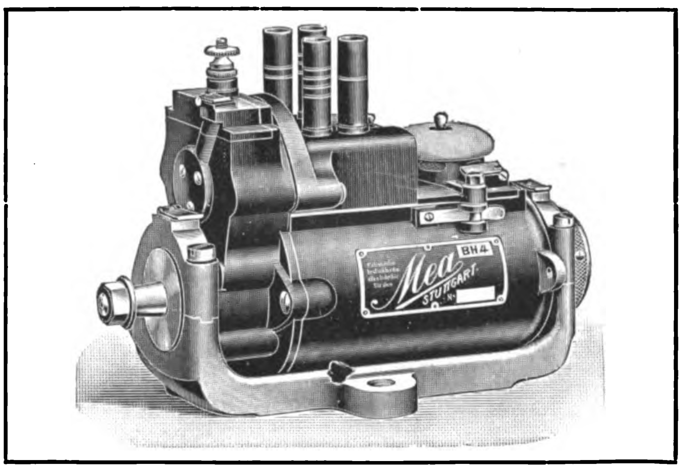

Fig. 87—BH4 Dual Mea Magneto.

vanced as the motor will ever require at the highest speed, and that notwithstanding this fact a retarded spark will be furnished which will permit of operating

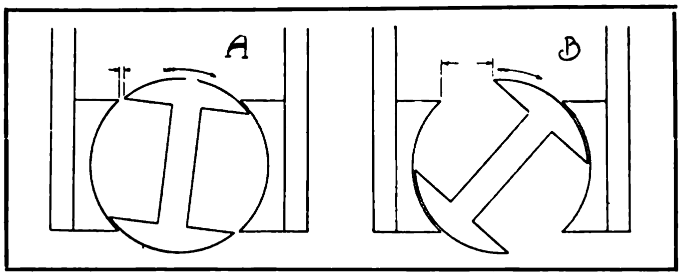

Fig. 88—Horseshoe Type Magneto: Relative Position of Magnets and Armature at Moment of Sparking in Advance Position (A), and Retard Position (B).

the engine at the lowest speed at which an explosive mixture can be drawn into the cylinders. Safety in starting is also emphasized. With the magneto timed to allow the highest motor speed, the spark can be retarded to a safe position for cranking. Another advantage claimed in the design is that the magneto will supply an intense spark when the motor is overloaded, as in hill climbing.

Mea Dual Equipment.

The Mea magneto is made to meet the requirements of different motors, including single and multiple-cylinder units, and a dual instrument is also marketed. The last named equipment comprises, in addition to the magneto, a Mea coil and switch, and differs from the standard design in that it is provided with a device for interrupting or breaking the battery or primary current.

A longitudinal section of the four-cylinder Mea magneto is shown at Fig. 92 B, the sketches A and C depicting the driving and breaker end respectively. It will be noted that the bell shaped magnet, with the poles in a horizontal line near the driven end of the magneto, partly encloses the armature, which rotates in ball bearings. The armature consists of a spindle or shaft carrying an I shaped iron core, which is wound with a heavy primary winding of few turns and a light secondary winding of many turns of wire. This armature shaft also carries the condenser, the collector ring and the low-tension breaker.

The circuit breaker is composed of a disc which carries a short platinum point contact and an insulated

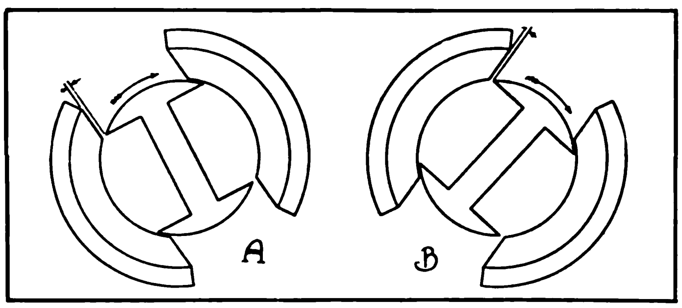

Fig. 89—Mea Magneto (Bell Shaped Magnet Type): Relative Position of Magnets and Armature at the Moment of Sparking in Advance Position (A), and in Retard Position (B).

plate which holds a spring supporting the other platinum contact point. This platinum point is adjustable. The circuit breaker or interrupter is operated by a fiber roller in connection with a cam disc, which is provided with two cams and is located within the breaker. The circuit breaker is parallel to the primary winding outside of the case, and is covered with a brass case or housing. In revolving with the armature the roller presses against the spring supported part of the breaker whenever it rolls over the two cams and in this manner opens the breaker, separating the platinum contact points twice every revolution of the armature.

Circuit Breaker Box.

The circuit breaker box is closed by a cover, which supports in its centre a carbon holder, by which the carbon member is pressed against the screw. The last named member connects at one end with the low-tension winding of the armature and at the other end with the core of the armature. The entire circuit breaker can be removed by displacing the screw referred to. The condenser is in parallel circuit with the circuit breaker and is fitted to the right armature cap. This serves to absorb the excess current induced by the breaking of the primary current.

The ends of the primary and secondary windings are metallically connected with the armature core and

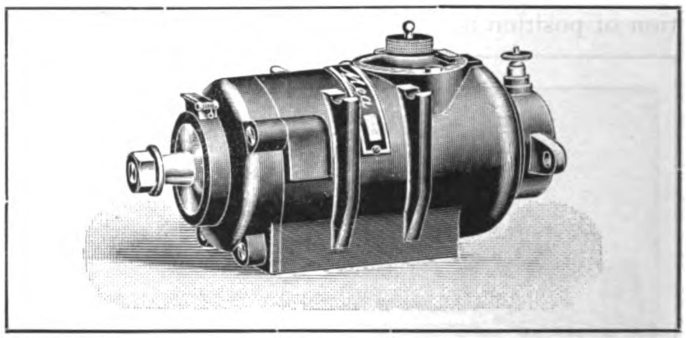

Fig. 90—The Mea Magneto Type A1.

consequently with the body of the magneto. The joint of the two wires is connected with a metal piece of the condenser, which is insulated from the armature shaft. The secondary wire is connected with a slip ring that is fitted to a vulcanite member, which is also insulated from the armature shaft. From this slip ring the high-tension current is conveyed through a carbon cylinder, carried by a holder and insulated from the cover, and thence to the distributor. A second carbon member, which is not insulated, slides on the right cap of the shuttle and serves to conduct the current from the armature to the body of the magneto.

Path of High-Tension Current.

The high-tension current is collected from the collector ring by a brush carried in a brush holder, also supported by a removable cover, the low-tension grounding brush being retained by the same cover, which relieves the ball bearings of all current that might have a deteriorating effect. The cover also carries the safety gap, which protects the armature from excess of voltage should the magneto become disconnected from the spark plugs.

The distributor is attached directly above the armature and it consists of a shell, a rotating member

driven by steel and bronze gears from the armature shaft, and the distributing finger. The shell and rotating member are of the best insulating material. Imbedded in the shell are four contact plates which are in metallic contact with the lead terminals at the top of the distributor, into which the ends of the cables connected with the different engine cylinders are inserted and retained.

The high-tension current is collected from the collector ring by a brush and brush holder, and reaches the distributor from a carbon member through the bridge and another carbon. It is conducted to the brushes, placed at right angles to each other, which make contact alternately with the four contact plates in the distributor shell. In the operation of the magneto the circuit breaker ordinarily short circuits the low-tension winding of the armature, and this short circuit is only broken when the breaker opens. When the knurled screw member is wired to a metal portion of the car, the frame for example, the primary circuit is diverted, or the instrument short circuited, so that it will not create energy.

Variation in timing is obtained by turning or rocking the bell shaped magnets in the stationary base by means of the lever connections at the side lugs and in the same manner as the conventional breaker box is rotated. The spark is advanced by turning the magnet in the direction opposite to the rotation of the armature, and is retarded by turning it in the direction of the rotation of the armature. The range of timing obtained with all medium and large sized magnetos for three, four, six and eight-cylinder motors is 70 degrees, or very nearly the fifth of a circumference of a circle.

The magneto is mounted in a frame or base so that the entire construction may be turned or rotated partially on its axis. The installation is such that the instrument may be removed from the frame easily by displacing the top parts or clamps retaining the bearings. Not only is the design small and light, but all working parts are protected from water, dust, etc. The breaker construction is such that even at the highest speeds the lightness of the parts insures accurate operation, while the centrifugal force has no undue influence upon the circuit breaker, because the circuit is broken parallel to the axis.

Setting the Magneto.

At Fig. 92 A will be noted a circular indicator or timing window that is protected by glass, through which may be seen the numbers marked on the distributor gear. This is of value in that it permits the magneto to be positively set after it has been removed from the base, obviating the trouble of ascertaining the position of the distributor by opening the distributor case. The cables are all marked so as to make replacement a certainty.

The type A magnetos involve the same principle of advancing and retarding the magnetic field as the B and C, differing mechanically in that they have no separate base, but a stationary shell inside of which the magnet is turned when changing the timing by means of the lugs. The main features of the B and C types are retained. The two-cylinder instruments are similar to the A except that the metal part of the slip ring extends over about 100 degrees and that two collecting carbons are provided. Only one carbon is connected to the high-tension winding at a time and the current is alternately sent to one or the other cylinder.

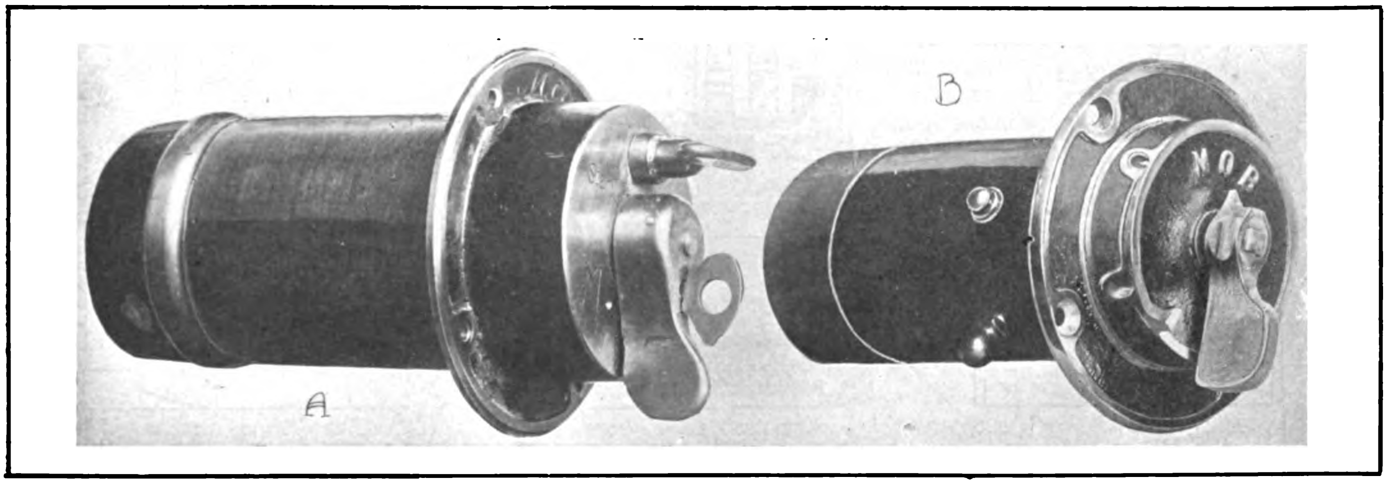

Fig. 91—Showing Dash Coils Utilized with Mea Dual Ignition: A, Type SS; B, Type SC.

As with all true high-tension magnetos, the wiring plan is very simple. In addition to the leads connecting the distributor with the spark plugs there is but one wire utilized, that employed for grounding the primary circuit or for stopping the operation of the motor.

Mea Dual Magneto Equipment.

The Mea dual magneto equipment, comprising a Mea magneto dynamo, coil and switch, does not differ in the main from the independent type. The system of connection required varies, however. The secondary or high-tension connections consist of wiring from the distributor to the spark plugs, in the same manner as with the independent type, and a connection from a high-tension switch to the magneto distributor, also one from this switch to the high-tension carbon holder. The primary wiring includes a connection from the magneto breaker to the switch utilized for grounding the magneto, and is identical with the wire used for this purpose with independent mag-

netos. There are also connections joining together the battery, coil and battery breaker of the magneto.

By means of these connections and the switch, the distributor is wired either to the magneto or to the high-tension side of the coil. Whenever the distributor is connected to the coil, the low-tension part of the switch grounds the breaker of the magneto, and closes the circuit to the battery breaker. When the distributor is connected to the magneto the switch disconnects the battery and opens the magneto ground connection. In this manner the distributor will be connected to the armature of the magneto when the instrument fires, and it is connected to the coil whenever the latter is operating.

Types of Coils Utilized.

The Mea dual equipments are supplied with a coil of the vibrator type which provides a number of sparks for every firing stroke of the motor. Designs are manufactured, however, with single-spark coils, and these may be fitted with the multiple-spark attachment. Both are of the horizontal dashboard type.

The dual magneto equipment differs only in the arrangement of the battery breaker. With the vibrator type of coil this breaker closes when the spark is desired, while with the single-spark type the breaker is normally closed and only opens at the instant of firing.

The Mea coil and switch of the vibrator type are shown at Fig. 91 B. All terminal posts are placed on the periphery of the coil close to the dashboard, and the vibrator is located at the end of the coil, where it can be reached easily when adjustments are necessary. The switch has three positions, these being "Battery", "Off" and "Magneto". No push button or special starting device is required. To start the motor from the seat the switch is moved to the battery position and then moved to the magneto side. The timing lever is always placed in a fully retarded position, in starting.

The single-spark type SS is shown at A. It comprises a mechanically actuated vibrator, by means of which a single spark or a number of sparks may be obtained as for starting from the seat. The system is operated by turning the lever to the battery position and moving slightly the starting device.

Timing the Magneto.

In timing the multiple magneto, place it in the position of its maximum advance by turning the magneto housing or timing lever in the direction opposite to that of the rotation of the armature. Remove the cover of the breaker box and turn the armature shaft in the direction of rotation until the figure 1 appears on the indicator and until the contact breaker opens. Turn the motor until the piston of the first cylinder (that nearest the radiator) is from .625 to .875 inch in advance of the dead centre. The secondary wires are attached according to the firing order of the motor and as explained in previous discussions on magnetos.

In installing magnetos on two-cylinder opposed motors, the instrument should be timed so that it will always fire on the terminal nearest the cylinder to be fired, as otherwise the wires will have to be crossed. This may be determined easily by opening one of the two covers and seeing with which high-tension carbon the metal segment is making contact.

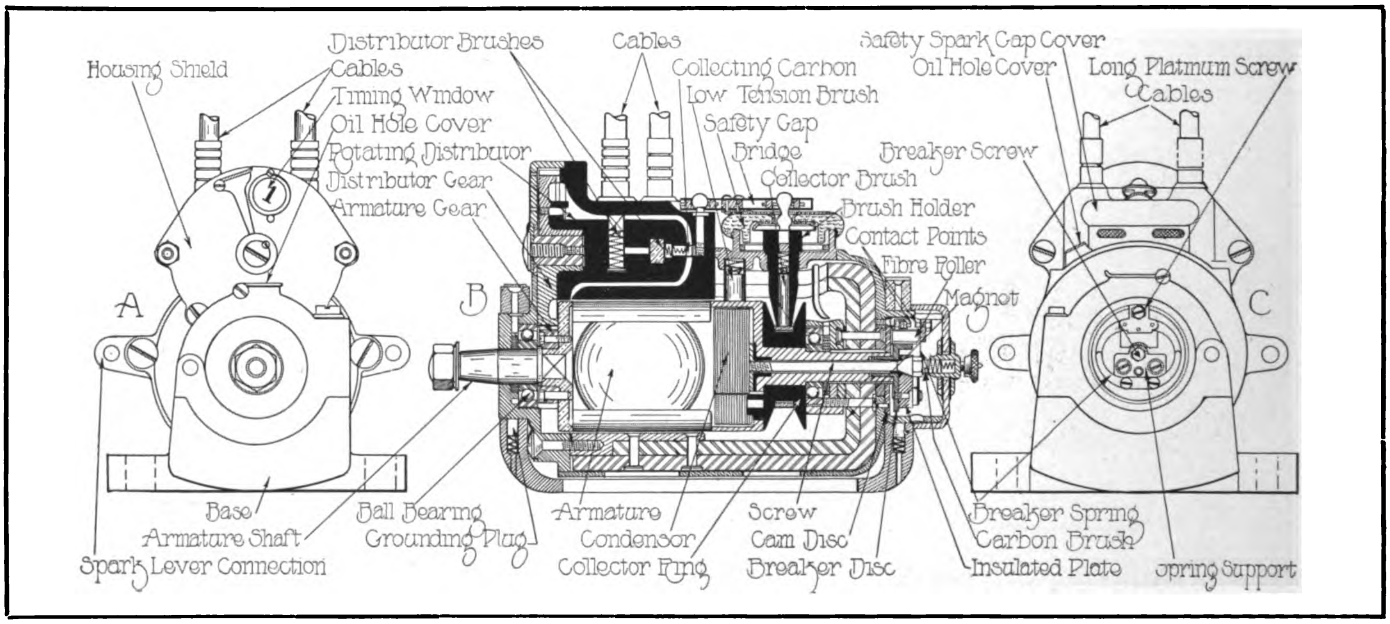

Fig. 92—The Mea Magneto Type BH4: A, the Driving End, Showing the Timing Window and Method of Oscillating Magnet; B, Sectional View; C, Breaker End.

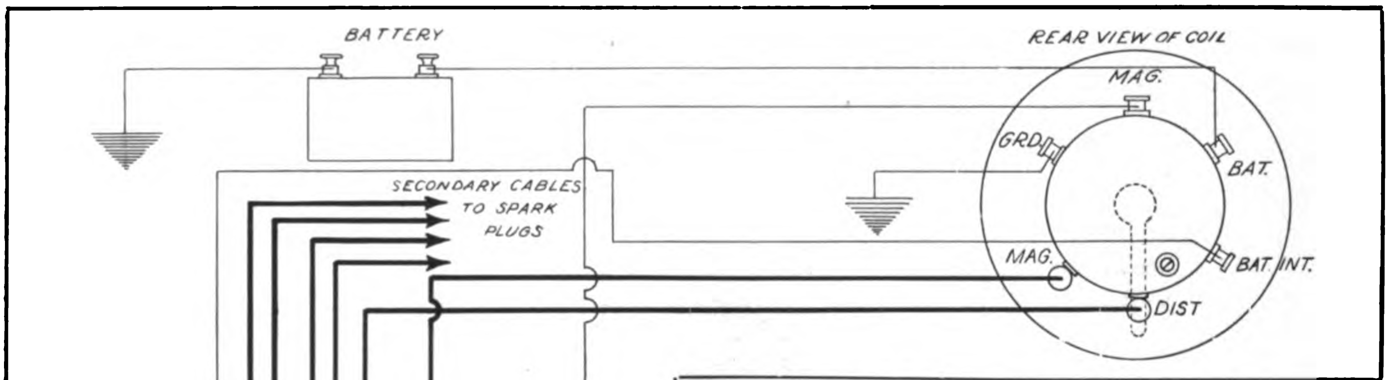
Replacing Magneto.

The resetting of the Mea, after it has been removed from a motor for cleaning or inspection, is simple. Before displacing the instrument, turn the motor or move the timing lever until one of the numbers appears on the indicator, then remove the magneto by opening up the base bearings and leave the engine undisturbed while the instrument is out of its base. In replacing see that the same number as before appears on the indicator. The identification of the cables is made easy by the number of rings on the hard rubber sleeves or terminals.

The opening of the platinum contact points should

be about .015625 inch, or slightly more, and the proper space is determined by the use of a wrench accompanying each instrument. The breaker may be removed from the box by loosening the long centre screw retaining the breaker to the armature, and screwing it into the small tapped hole provided in the breaker so that it may be used as a handle in lifting the breaker out. In replacing the breaker the small pin at its back must be introduced into the slot provided for it in the armature shaft and care must be taken not to tighten the screw until the pin is in its proper place.

The maker of the Mea recommends a spark plug gap of .015625 inch. The breaker must not be lubricated or the top cover supporting the high-tension carbon removed while the magneto is operating. This cover contains the safety spark gap, and if displaced



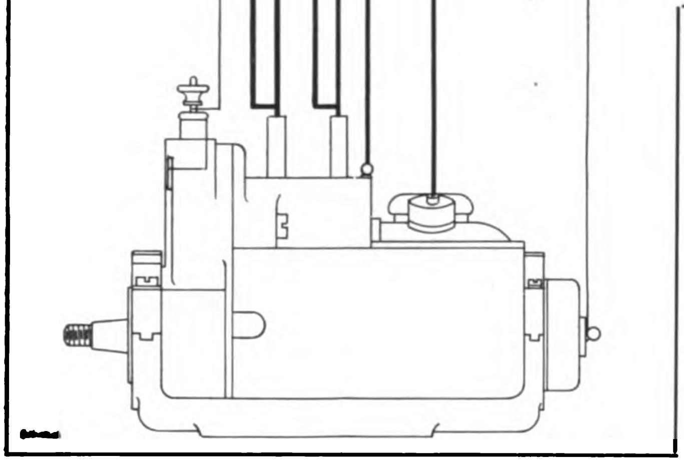


Fig. 93—Wiring Diagram of Mea Dual Magneto, Including Storage Battery and Dash Coil.

is likely to injure the winding of the armature. It requires no attention.

Timing Dual Equipment.

To time the dual equipment magneto the caps over the battery and magneto breakers are removed and the instrument fully retarded. The armature is then rotated until the figure 1 on the distributor gear is opposite the red line on the housing, and until the magneto breaker just begins to open. The motor is then turned to dead centre of the first cylinder, and if the engine is of the four-cylinder type, about 1.5 inches beyond, measuring on the circumference of the flywheel, or from .0625 to .09375-inch downward on the firing stroke. With six-cylinder motors it is preferable to time full retard slightly beyond dead centre.

CONTRACT DELIVERY SERVICE.

High Class Distribution at Minimum Expense Attractive to Business Men.

The practical saving that can be made by contract delivery, eliminating duplication of service and insuring satisfaction to customers, such as has been developed to a limited extent in a number of cities, is extremely attractive to business men, according to W. S. Pettit, sales manager of the Commerce Motor Car Company, Detroit, Mich., who maintains that considerable attention is being given to study of the possibilities of such contracting companies. Many small stores limit patronage because of lack of delivery facilities, and others cannot meet the demands that are made by customers through dependence upon express companies or messengers. Occasional deliveries are necessarily more expensive, and they are not systematically made.

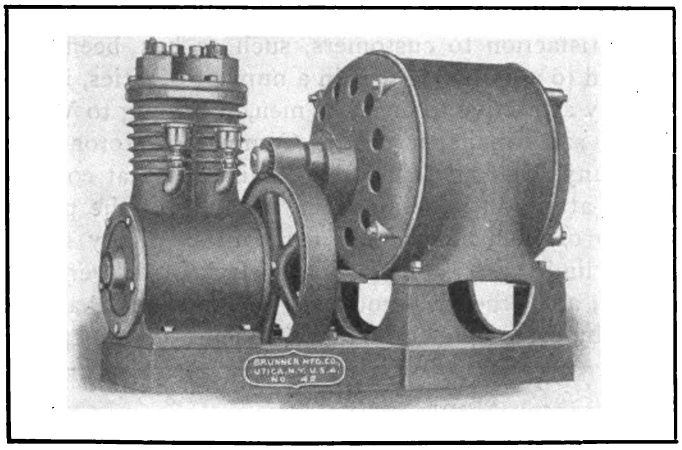
Inquiries made by some of the manufacturers indicate that a decided attention has been given the possibilities of organizing concerns for contracting with small stores, either by distributing from a central location where the goods are sent by the stores, or by collecting packages consigned to different localities by the vehicles covering the routes. The conclusion of those who have studied the problem in different localities is that a vehicle of 1000 pounds capacity, that can be fitted with a covered body that will carry bulky bundles, and equipped for convenient handling, will afford the best service in average conditions.

Economy of operation, speed and reliability are three important factors, and simplicity of construction and durability in service are absolutely essential. With businesses that will not support delivery equipment individually a contractor, by careful routing and good supervision, can combine a number so as to materially increase the satisfaction of the customers, extend the radius from which patronage is drawn and realize a reasonable profit.

The Mogul Motor Truck Company, Chicago, Ill., has appointed Charles Fisher, formerly with the Universal Motor Truck Company of Detroit, sales manager of the territory east of Chicago. He will have offices in New York City.

GARAGE AND SERVICE STATION EQUIPMENT.

MOTOR driven compressors are now considered standard equipment in the repair shop and service station, the design varying according to the service required. The Brunner Manufacturing Company, Utica, N. Y., is producing a number of different types, that shown in the accompanying illustration being adaptable to many varying classes of service. The complete outfit is self-retained and operates with so little vibration that it can be installed, if desired, without fastening to the floor.



Parker Double-Cylinder Motor Driven Air Compressor.

The No. 42 Parker outfit, as it is termed, comprises, in addition to the motor, a double-cylinder vertical compressor with cylinders having a bore of 1.825 inches and stroke of 2.5. The guaranteed pressure with a standard motor is 130 pounds to the square inch, although the compressor can be fitted for higher pressures upon order.

Lubrication is by the splash system and the motor bearings are oiled by ring oilers on the shaft. The height is 16.5 inches and the floor space required is 18.5 by 11 inches. The net weight is 170 pounds; shipping weight, 200.

Energy is supplied by a .5 horsepower electric motor, and drive is by a cast iron spur gear and a rawhide pinion. The compressor is driven at a speed of 350 revolutions a minute, and has a capacity of 4480 cubic inches (2.5 cubic feet) of free air a minute. The outlet is tapped for a .25-inch iron pipe. The finish is gloss black enamel. The motor is a direct current machine or single-phase alternating current, 110 or 220 volts. Motors of any frequency on alternating current are supplied at an extra cost.

The outfit can be made automatic with an electric controller and any desired pressure can be maintained day or night without any other attention than an occasional oiling. Two types of controllers are shown in an accompanying illustration, that at the left being designed for service with single or two-phase alternating current motors of two horsepower and less. The No. 91 is shown at the right and is similar to the other, but has a rheostat for all direct current motors and such alternating current motors as require starting resistance or a rheostat.

As previously stated, these controllers maintain a constant air pressure at all times and are stated to be extremely accurate and reliable. They can be adjusted for operation on a wide variation of pressure, or set to start and stop the motor within a variation in the tank pressure of two or three pounds, if desired. The construction is simple, only two diaphragms being used, these presenting such a small portion of their area to the pressure that they are practically wear proof. The contact points are of the wiping variety, insuring a clean surface at all times, and eliminating sparking.

The Brunner Manufacturing Company is issuing a new catalogue illustrating and describing air compressors, which will be mailed free.

MOVABLE LIGHT STAND.

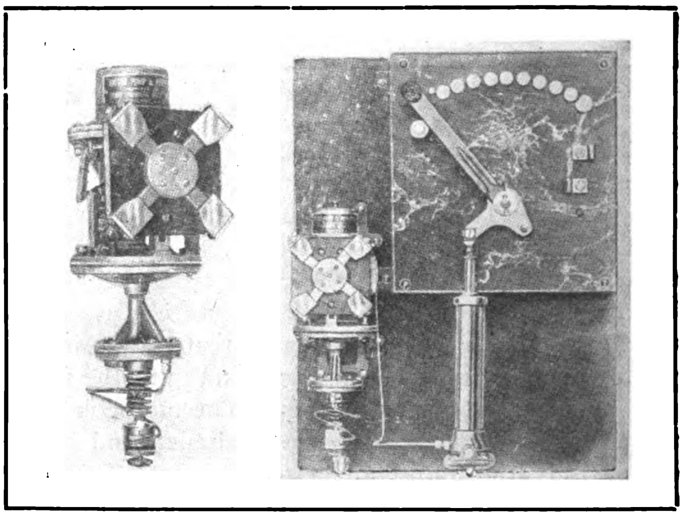
The Muller Manufacturing Company, East New Durham, N. J., has brought out a new light stand which is mounted on casters, permitting its use about the garage. A cluster of four bulbs is employed with a suitable reflector and the latter is adjustable. Sufficient length of lamp cord and a socket are supplied with each equipment, which is moderately priced.

GLYCO REINFORCED BEARING.

The Glyco bearing is being marketed by Joseph T. Ryerson & Son, Chicago, and it is claimed that by a bronze or steel reinforcement of skeleton construction the body and flange are greatly strengthened.

GENTER'S METALLIZED PAINT.

The J. H. Genter Company, Inc., Newburgh, N. Y., is marketing a metallized paint which is intended to withstand extreme high temperatures. It is stated that the three shades of copper will successfully survive a heat of 900 degrees Fahrenheit, and at the other



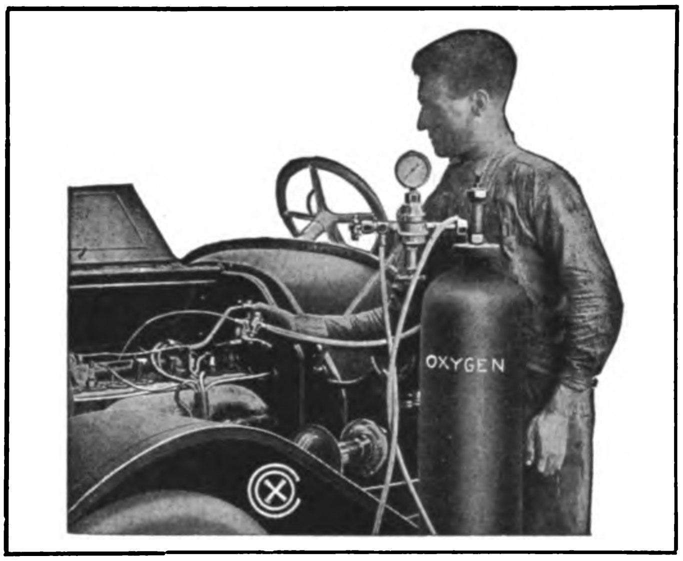
Electric Controllers Utilized with Parker Air Compressors.

end of the scale come black, brown and red, which, it is claimed, will remain unaffected under a heat of 2200 degrees.

COX OXYGEN CLEANER.

The introduction of the oxygen process for removing carbon from the cylinders of internal combustion motors has not only eliminated the necessity of pulling down the cylinders, but considerable labor is saved. Some of the advantages derived by the use of the new method are noted by the statement of a manufacturer who claims that the average four-cylinder engine can be cleaned in 30 minutes and a six-cylinder in 45. Another quality of the system is that deposits are removed from crevices, etc., not accessible with the scrapers.

The Cox Brass Manufacturing Company, Albany, N. Y., is marketing the Cox oxygen carbon cleaner, which equipment is shown in an accompanying illustration. It comprises a tank of oxygen with pressure



The Oxygen Carbon Cleaner Equipment Marketed by the Cox Brass Manufacturing Company, and Method of Use.

gauge, etc., and a flexible arm which is inserted through the spark plug opening of the cylinder. Means for controlling the flow of the mixture are provided, as shown in the illustration, and the oxygen consumes the carbon without affecting the metal. It is pointed out by the maker that a large number of motors may be cleaned during a week and that the cost is slight.

The equipment is constructed of high grade material, and high class workmanship characterizes all the products of this company, and each outfit is tested carefully before being shipped from the factory. The oxygen tanks are loaned, the only charge made being for the refill. The Cox oxygen carbon cleaner equipment is moderately priced and the maker has an interesting proposition for the trade.

HOYT FORD MAGNETO TESTER.

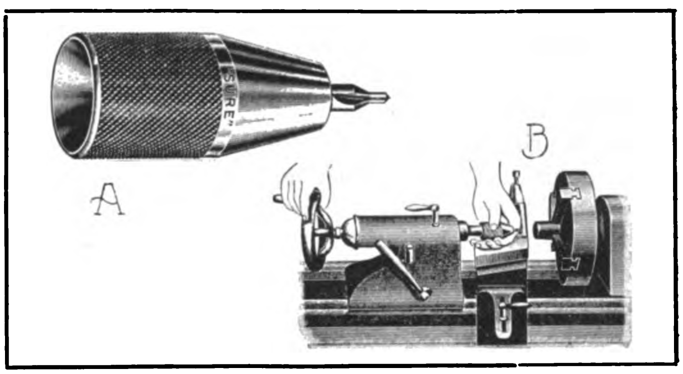
One of the most difficult troubles to locate with the model T Ford motor is the ignition, and many times weak magnets are the cause of the cylinder heating and lack of power. The Hoyt Electrical Works, Penacook, N. H., maker of current testing devices, is marketing the Hoyt Ford magneto tester, shown in an accompanying illustration. The meter is very compact, being 3.5 inches in diameter, and is constructed with the same care and high grade material for which the product of this concern is noted.

Hoyt Ford Magneto Tester.

The dial of the instrument is calibrated, providing three chief points, these being "Poor", "Medium" and "Good". The meter is fitted with two cables or leads and either may be utilized in connection with the magneto terminal. The remaining lead is grounded. The Hoyt Ford magneto tester is moderately priced and should prove especially useful to Ford service stations, repair shops and where a fleet of the Ford cars is maintained.

SURE CENTRE FINDER.

The West Haven Manufacturing Company, New Haven, Conn., is marketing the Sure centre finder, a new lathe tool, shown in an accompanying illustration. It has a socket that fits on the 60-degree angle taper of centre of the tail stock of the lathe, and when held in that position and fed up to the work held and revolving in the chuck, it immediately locates the centre. The friction of the centre finder on the lathe centre is sufficient to hold for drilling and countersinking, enabling the workman to make the three operations without change or use of any other tool. The fingers need do more than steady the tool. Each centre finder is sent out with a combination drill and countersink, which are stock sizes with any maker. The Nos. 0 and 1 have a short single-end drill and countersink about



West Haven Sure Centre Finder: A, Finder; B, Method of Use.

half the length of the double-end ones on the market, for the sake of compactness, but the double-end ones may be used, however.

HINTS FOR PROPER MAINTENANCE.

IN THE event of a broken crankshaft the usual method is to obtain a new one from the factory, but if the car is an old one and a new part cannot be secured it may be necessary to buy a drop forged crank in the rough and turn it up. Sometimes in the overhaul it is found that the crankpin is worn oval and will not yield to ordinary methods, and when such is the case a light cut is taken. The Strasburger Manufacturing Company, 326 Madison street, Chicago, is marketing combination lathe dogs, which are shown at Fig. 2, and these members are adjustable from two to six inches. They are designed for holding all kinds of crankshafts, such as utilized in automobile and marine engines, and other power plants, and can be employed wherever a common lathe dog can be used.

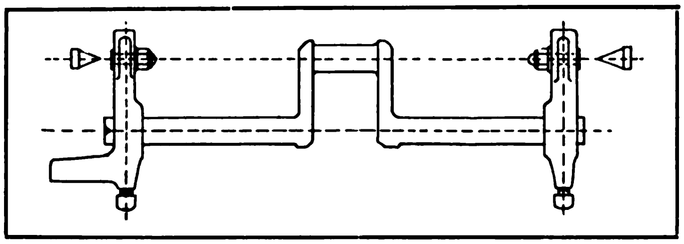


Fig. 1—Using Combination Lathe Dogs for Turning up the Crankshaft.

The design illustrated at C is adapted for turning heavy work, such as motor truck engine crankshafts, and is adjustable from two to eight inches. It is provided with screw feed centre and gauge, and each type of dog is constructed of the best malleable iron with case hardened steel screws.

The company points out that the turning up of a crankshaft has always been accomplished under certain difficulties except in shops where they are made in large numbers, and where special machines are required. As crankshafts are now forged in nearly all sizes and forms, and may be procured at a reasonable cost in the rough, it is possible to turn these up in the lathe by the following process:

Assuming that a four-throw crankshaft is to be finished, although single and double ones are more common to the repairman: The first step is to centre the work, either by laying off and centring in the drill press or in the lathe with the use of a steady rest. The driving dog is fastened at one end and the work placed between centres.

The bearings, front, centre and rear, are roughened down to within .03125 or .0625 inch of the finished size. The straight or tailless dog is then fastened on the other end and one-half of the stroke is measured from the centre of the crank to the centre hole in the adjustable screws, and the nuts securely tightened. The work is then placed between the adjustable centres and lined up parallel by running the lathe carriage back and forth.

The second and third pins should be roughened down to within .03125 or .0625 inch of the finished size. The dogs should now be loosened and the crank given half a turn, the first and fourth pins lined up parallel, and finished to exact size. After this is done the dogs are again loosened and the crank given half a turn back and lined up parallel to finish the second and third pins to exact size.

The four pins are now finished to size, so the straight dog and the counter-balance should be taken off, and the crank placed between centres. The centre bearing is then finished to size and the steady rest applied, while the front and rear bearings are being finished to size. Care should be taken not to have the tailstock centre too tight during the finishing cuts.

The large face plate should be used for this operation and a weight clamped to it for a counter-balance. If the crank should have a flange on one end, it may be chucked and a four-jaw chuck used instead of the face-plate, then only one dog will be necessary. If a heavy cut be desired or the tool chatter, the steady rest can be used on one pin, while the other pin is being turned down.

BUILDING UP BEARINGS.

The following suggestion is made by a workman, for adjusting the small ends of connecting rods where considerable play exists: Press the bushing out of position in the vise and sweat a layer of solder onto the outside surface. After pressing the part into position again it will be found to be smaller than before and the wristpin can be refitted.

SOFTENING CAST IRON.

To soften cast iron for drilling, heat the part to a cherry red, and have it lie level in the fire. Then with the tongs put on a piece of brimstone, a little smaller in size than the hole to be drilled. This softens the iron entirely through. Let the piece remain in the fire until cooled.

The following suggestion for eliminating cotter pins and preventing nuts from working loose on the spring clips, brake drums, etc., is contributed by a driver: Make a saw cut in the bolt, screw up the nut, then spread the bolt with a chisel.

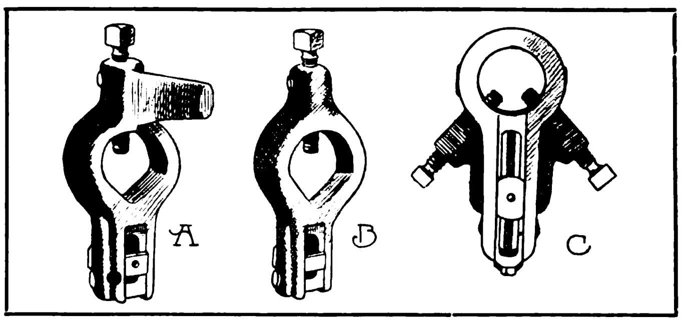

Fig. 2—A and B, Adjustable Combination Lathe Dogs; C, Design for Heavy Work.

"LOGGING" NEAR THE METROPOLIS.

Five-Ton G. M. C. Truck Hauling Timber Cleared from New Yorker's Big Estate.

Those who have occasion to speak of New York City regard it as further removed than all cities of the nation from industries associated with the country, and, in some instances, with what might be termed the wilderness of civilization. New York is a city of enormous proportions and the municipality itself contains more people than any single state aside from New York State itself, and when the commuters from the suburbs—for practically every city, town and village within 50 miles is so regarded—and the half million daily visitors are considered, it will be understood that there is within the radius stated a population hardly conceivable.

New York City itself is in a state of transition, and to the critical visitor this aspect is always emphasized by the building operations, but aside from construction one might assume there was little else than commerce and manufacturing to employ the multitude of inhabitants. But, strange as it may appear within comparatively short distances of the commercial centre of New York City, which is generally spoken of as Broadway, there are men engaged in work that might be associated with the mountains or the remote country. This fact is emphasized by the recent purchase of a five-ton G. M. C. truck by George B. Tompkins, who has a very large estate, that can be reached in less than 45 minutes from Grand Central terminal, who is using it in hauling timber that he is cutting in clearing his property, as he is delivering logs of large size to New York lumber dealers. The logs are cut on the estate and are hauled with a trailer to different points where they are shipped or stored for use later on. The high price of timber makes the sale of the logs extremely profitable, and the truck, which is doing work that was done by eight horses, is regarded as a very satisfactory investment.

INTERNATIONAL GETS MORE TIME.

Extension of Notes and Loans for Three Years and Other Creditors Preferred.

The temporary injunction obtained by minority stockholders of the International Motor Company to permit an inquiry into the proposal of the company to place a mortgage of $1,200,000 on its property, pending determination of the proposition judicially, and with the possible object of bringing about a receivership, has been dissolved by Judge Garretson of the New York supreme court, and the company will now make effective a plan evolved for the purpose of strengthening it financially.

The details of the plan have been worked out and comprehend that all the bank loans and notes payable, which aggregate $2,500,000, have been extended, both principal and interest, for three years from Nov. 1, 1913. These obligations have been subordinated to the claims of the merchandise creditors, who will have prior claim on the assets of the company save for a mortgage of $48,000 on the plant at Plainfield, N. J., which remained when the property was acquired from the Saurer Motor Company, and a mortgage of $6500 on Newark, N. J., real estate, which remained when this realty was bought as a service station for the company.

In other words, indebtedness aggregating $2,500,000 has been deferred three years and the merchandise creditors will have first claim on the assets after mortgages aggregating $54,500 have been satisfied. The claim of the company is that the assets, exclusive of licenses, patent rights, good will, etc., amount to more than $5,000,000, and that the claims of the merchandise creditors are approximately $300,000.

George E. Blakeslee, the petitioner, maintains that his suit for the dissolution of the company will be continued to a finality.

C. J. Rohrer of the General Electric Company, Schenectady, N. Y., will read a paper on "Small Motor Applications for Farm Work" at the seventh annual convention of the American Society of Agricultural Engineers, to be held at the Great Northern hotel, Chicago, Ill., Dec. 29-31. Part of the session will be devoted to the consideration of various types of motor farming apparatus.
